THE COMPLETE DICTIONARY OF ARTS and SCIENCES.

IN WHICH THE WHOLE CIRCLE OF
HUMAN LEARNING
IS EXPLAINED,

And the DIFFICULTIES attending the Acquisition of EVERY ART,
Whether LIBERAL or MECHANICAL, are Removed,
IN THE MOST EASY AND FAMILIAR MANNER.

Among the various Branches of LITERATURE explained in this Work are the following, viz.

AGRICULTURE	ETHICS	HYDROGRAPHY	PAINTING
ALGEBRA	FLUXIONS	HYDROSTATICS	PERSPECTIVE
ANATOMY	FORTIFICATION	LAW	PHARMACY
ARCHITECTURE	GARDENING	LEVELLING	PHILOLOGY
ARITHMETIC	GAUGING	LOGIC	PHILOSOPHY
ASTRONOMY	GEOGRAPHY	MARITIME AND	PHYSIC
BOTANY	GEOMETRY	MILITARY AFFAIRS	PNEUMATICS
CATOPTRICS	GRAMMAR	MATHEMATICS	RHETORIC
CHEMISTRY	GUNNERY	MECHANICS	SCULPTURE
CHRONOLOGY	HANDICRAFTS	MERCHANDIZE	SERIES
COMMERCE	HERALDRY	METAPHYSICS	STATICS
CONICS	HISTORY	METEOROLOGY	STATUARY
COSMOGRAPHY	HORSEMANSHIP	MUSIC	SURGERY
DIALLING	HUSBANDRY	NAVIGATION	SURVEYING
DIOPTRICS	HYDRAULICS	OPTICS	THEOLOGY, &c.

The THEOLOGICAL, PHILOLOGICAL, and CRITICAL BRANCHES, by
The Rev. TEMPLE HENRY CROKER, A. M.
Chaplain to the Right Honourable the Earl of HILLSBOROUGH.

The MEDICINAL, ANATOMICAL, and CHEMICAL,
By THOMAS WILLIAMS, M. D.

The MATHEMATICAL
By SAMUEL CLARK,
Author of an Easy Introduction to the Theory and Practice of Mechanics.

AND THE OTHER PARTS BY
Several GENTLEMEN particularly conversant in the Arts or Sciences they have undertaken to explain.

V O L. III.

THE COMPLETE O F DICTIONARY OF ARTS and SCIENCES.

QUA

Q a consonant, and the sixteenth letter of the alphabet, and, though it is not in the old Greek or Latin alphabet, is yet derived from the more ancient Hebrew Δ , by turning the character and making the angular apex round, and carrying the perpendicular part obliquely under the round one; and from thence also the modern Hebrew character $\aleph$ koph of the same letter. In the Latin, the use or disuse of the Q seems to have been so little settled, that the poets used the Q or C indifferently, as best suited their measures; it being a rule, that the C imported them to be divided. The Saxons had not this letter, but expressed it by *c p*, as in *cpacian*, to quake, &c.

In the French, the sound of the Q and K are so near akin, that some of their nicest authors think the former might be spared.

In English, the Q is formed in the voice in a different manner from K, the cheeks being contracted, and the lips, especially the under one, put into a cannular form for the passage of the breath. It is, however, never sounded alone, but in conjunction with *u* after it either in Latin or English, as in *qualis*, *quantum*, *qualm*, *queen*, *oblique*, &c. and it never ends any English word.

As a numeral, Q stands for 500; and with a dash over it, thus $\overline{Q}$, for 500000.

Used as an abbreviation, *q* signifies *quantity* or *quantum*: thus, among physicians, *q. pl.* is *quantum placet*, that is, as much as you please of a thing; and *q. s.* *quantum sufficit*, that is, as much as is necessary. *Q. E. D.* among mathematicians is *quod erat demonstrandum*, that is, which was to be demonstrated; and *Q. E. F.* *quod erat faciendum*, that is, which was to be done. *Q. D.* among grammarians, is *quasi dictum*, that is, as if it were said, or, as who should say.

QUACK, among physicians, the same with empiric. See the article EMPIRIC.

QUADRA, in building, any square border encompassing a basso relievo, pannel, painting, or other work.

QUADRAGESIMA, a denomination given to Lent, from its consisting of forty days. See the article LENT.

QUA

Hence also the first Sunday of Lent is called Quadregesima Sunday, and the three preceding Sundays, Quinquagesima, Sexagesima, and Septuagesima.

QUADRANGLE, in geometry, the same with quadrilateral figure, or one consisting of four sides and four angles. See QUADRILATERAL.

QUADRANT, QUADRANS, in geometry, an arch of a circle, containing 90° , or one fourth part of the whole periphery. The space or area included between this arch and two radii drawn from the center, to each extremity thereof, is called a quadrant, or, more properly, a quadrantal space, as being a quarter of an entire circle.

QUADRANT also denotes a mathematical instrument, of great use in astronomy, navigation, &c. for taking of altitudes, angles, &c. It is variously contrived, according to the various uses it is intended for, but they all have this in common, that they consist of a quarter of a circle, whose limb is divided into 90° : some have a plummet suspended from the center, and furnished with pinnulae or sights to look through.

The principal and most useful quadrants are the common or surveying quadrant, astronomical quadrant, Davis's quadrant, Hadley's quadrant, horodictical quadrant, Gunter's quadrant, Sutton's or Collins's quadrant, and the finical quadrant.

1. The common or surveying quadrant, (plate CVII. fig. 1.) is made of brass, wood, or any other solid substance; the limb of which is divided into 90° , and each of these farther divided into as many equal parts as the space will allow, either diagonally or otherwise. On one of the semi-diameters are fitted two moveable sights, and to the center is sometimes also fixed a label, or moveable index, bearing two other sights; but in lieu of these last sights there is sometimes fitted a telescope; also from the center there is hung a thread with a plummet; and on the under side, or face of the instrument is fitted a ball and socket, by means of which it may be put into any position. The general use of it is for taking angles in a vertical plane, comprehended under right lines going from the center of the instrument, one of which is horizontal,

and the other is directed to some visible point. But besides the parts already described, there is frequently added on the face near the center, a kind of compartment, called the quadrat, or geometrical square; as in the figure.

This quadrant may be used in different situations: for observing heights or depths, its plane must be disposed perpendicularly to the horizon; but to take horizontal distances, its plane is disposed parallel thereto: again, heights and distances may be taken two ways, viz. by means of the fixed sights and plummet, or by the label.

Use of the Surveying QUADRANT.—To take the height or depth of an object, with the fixed sights and plummet, place the quadrant vertically, and the eye under the sight next the arch of the quadrant; thus direct the instrument to the object, suppose the top of a castle, &c. till the visual rays thereof strike through the sights upon the eye.

This done, the portion of the arch intercepted between the thread and the semi-diameter, whereon the sights are fastened, shews the complement of the object's height above the horizon or its distance from the zenith; and the other portion of the arch, between the thread and the other semi-diameter, shews the height itself of the object above the horizon. The same arch likewise gives the quantity of the angle made by the visual ray, and a horizontal line parallel to the base of the tower. To observe depths, the eye must be placed over that sight next the center of the quadrant.

From the height or depth of the object, in degrees thus found, which suppose $35^{\circ} 35'$; and the distance of the foot of the object from the place of observation carefully measured, which suppose 47 feet; its height or depth in feet, yards, &c. is easily determined by the most common case in trigonometry.

For we have here in a triangle one side given; namely the line measured, and we have all the angles; for that of the castle is always supposed a right angle; the other two, therefore, are equal to another right angle; but the angle observed is $35^{\circ} 35'$, therefore, the other is $54^{\circ} 25'$.

The case then will be reduced to this: as the sine of $54^{\circ} 25'$, is to 47 feet; so is the sine of $35^{\circ} 35'$, to a fourth term thirty-three feet and a half; to which add the height of the observer's eye, suppose five feet, the sum thirty-eight feet and a half is the height of the castle required.

As to the taking of altitudes of objects accessible, or inaccessible, see ALTITUDE.

2. *Astronomical QUADRANT*, is an instrument contrived to take the altitude, &c. of the heavenly bodies in a very accurate manner.

This instrument is generally made of brass, or wooden bars faced with plates of iron, having its limb *fe* (fig. 2.) divided either diagonally or otherwise into degrees, minutes, and seconds, if possible, with two telescopes; one fixed on the side of it, as *ab*, and the other *cd* moveable upon the center, by means of the screw *g*. And by means of screws and the dented wheels *h, i*, together with the screw *b*, it is easily directed to any object, or phenomenon.

3. *Davis's QUADRANT*, so called from its inventor captain Davis; and is no other than a common quadrant, lessened in one part of the arch, by supposing it to be divided into two different arches by a concentric circle, whereby the instrument becomes more portable.

It consists of two arches, and three vanes. See (fig. 3.) The arch *fg* contains commonly 60 deg. whence it is generally called the sixty arch, and is numbered from *f* towards *g*. The other arch *de* contains 30 degrees, or the complement of the former, being numbered from *e* towards *d*. On the surface of this arch are described 12 concentric circles, whereby each deg. by the help of diagonal lines, is divided into 12 equal parts, and consequently the altitude may be obtained to 5 minutes. The sight vane *A* is a piece of wood or brass, of about three inches long and one broad, and is fitted to slide on the arch *de*; in the middle of this vane is drilled a fine hole, through which both the solar spot, or shadow, and horizon are to be viewed at the time of observation. The horizon vane *B* is of about the same length and breadth as the former; and at the time of observation is fixed at *B*; it has a slit cut through it of about an inch long, and

a quarter of an inch broad, through which the horizon is to be observed. The shade vane *C* is fitted to the arch *de*, and has generally a convex lens set therein, which casts the solar spot on the horizon vane at the time of observation, being one of the many inventions of the celebrated Mr. Flamsteed.

To find the sun's altitude by this instrument: fix the shade vane *C* on the 60° arch, at about 15 or twenty degrees less than the complement of the altitude, and turning your back towards the sun, move the sight vane *A* up and down the arch *de*, till the sun's image fall on the horizon vane *B*, and at the same instant you see the horizon through the slit in the horizon vane; then will the degrees cut by the shade vane *C*, on the arch *fg*, being added to those cut by the sight vane *A*, on the arch *de*, be the sun's zenith distance at that time, which being subtracted from 90 degrees, will give his altitude.

But to obtain the sun's greatest altitude, or altitude when he is in the meridian, which is required in finding the latitude, continue observing, and as the sun approaches the meridian, the sea will appear through the slit in the horizon vane, and then must the slit vane be removed lower. And thus continue observing, till the sun be in the meridian, and, as soon as he begins to decline, the sky will appear thro' the slit in the horizon vane, when your observation will be finished, and the degrees on the sixty arch being added to those on the thirty arch will give the complement of the sun's meridian altitude or zenith distance, as before.

4. *Gunter's QUADRANT*, so called from its inventor Edmund Gunter, is represented in plate CVII. fig. 4. and besides the apparatus of other quadrants, has a stereographical projection of the sphere on the plane of the equinoctial. It has also a calendar of the months, next to the divisions of the limb.

Use of Gunter's QUADRANT. 1. To find the sun's meridian altitude for any given day, or the day of the month for any given meridian altitude. Lay the thread to the day of the month in the scale next the limb; and the deg. it cuts in the limb, is the sun's meridian altitude. Thus the thread being laid on the 15th of May cuts $59^{\circ} 30'$, the altitude sought; and contrarily the thread, being set to the meridian altitude, shews the day of the month. 2. To find the hour of the day. Having put the bead, which slides on the thread, to the sun's place in the ecliptic, observe the sun's altitude by the quadrant; then, if the thread be laid over the same in the limb, the bead will fall upon the hour required. Thus suppose on the 10th of April, the sun being then in the beginning of Taurus, I observe the sun's altitude by the quadrant to be 36° ; I place the bead to the beginning of Taurus in the ecliptic, and lay the thread over 36° of the limb; and find the bead to fall on the hour-line marked 3 and 9; accordingly the hour is either 9 in the morning, or 3 in the afternoon. Again, laying the bead on the hour given, having first rectified, or put it to the sun's place, the degree cut by the thread on the limb gives the altitude. Note, the bead may be rectified otherwise, by bringing the thread to the day of the month, and the bead to the hour-line of 12. 3. To find the sun's declination from his place given, and contrariwise. Set the bead to the sun's place in the ecliptic, move the thread to the line of declination *ET*, and the bead will cut the degree of declination required. Contrarily, the bead being adjusted to a given declination, and the thread moved to the ecliptic, the bead will cut the sun's place. 4. The sun's place being given, to find his right ascension, or contrarily. Lay the thread on the sun's place in the ecliptic, and the degree it cuts on the limb is the right ascension sought. Contrarily, laying the thread on the right ascension, it cuts the sun's place in the ecliptic. 5. The sun's altitude being given, to find his azimuth, and contrariwise. Rectify the bead for the time, as in the second article, and observe the sun's altitude; bring the thread to the complement of that altitude; thus the bead will give the azimuth sought among the azimuth lines. 6. To find the hour of the night from some of the five stars laid down on the quadrant. 1. Put the bead to the star you would observe, and find how many hours it is off the meridian, by article 2. Then, from the right ascension of the star subtract the sun's right ascension converted into hours, and

and mark the difference: which difference, added to the observed hour of the star from the meridian, shews how many hours the sun is gone from the meridian, which is the hour of the night. Suppose on the 15th of May the sun is in the 4th degree of Gemini, I set the bead to Arcturus; and, observing his altitude, find him to be in the west about 52° high, and the bead to fall on the hour-line of 2 in the afternoon; then will the hour be 11 hours 50 minutes past noon, or 10 minutes short of midnight: for 62° , the sun's right ascension, converted into time, make 4 hours 8 minutes, which subtracted from 13 hours 58 minutes, the right ascension of Arcturus, the remainder will be 9 hours 50 minutes, which added to 2 hours, the observed distance of Arcturus from the meridian, shews the hour of the night to be 11 hours 50 minutes.

Hadley's QUADRANT, the most useful instrument for taking altitudes at sea, yet extant. It has its name from its inventor, J. Hadley, Esq; and is compounded of the following particulars. 1. An octant, or $\frac{1}{8}$ part of a circle, ABC. 2. An index D. 3. The speculum E. 4. Two horizontal glasses, F, G. 5. Two screens, K, K. 6. Two sight-vanes, H, I. plate CVII. *fig. 5.*

The octant consists of two radii, AB, AC, which are strengthened by the braces L, M, and the arch BC; which though containing only 45° , is nevertheless divided into 90 primary divisions, each of which stands for degrees, and are numbered 0, 10, 20, 30, &c. to 90; beginning at each end of the arch, for the convenience of numbering both ways, either for altitudes or zenith-distances: again, each degree is subdivided into minutes.

The index D, is a flat bar, moveable round the center of the instrument; and that part of it which slides over the graduated arch, BC, is open in the middle, with Vernier's scale on the lower part of it; and underneath is a screw, serving to fasten the index against any division.

The speculum E, is a piece of flat glass, quicksilvered on one side, set in a brass-box, and placed perpendicular to the plane of the instrument, the middle part of the former coinciding with the center of the latter. And, because the speculum is fixed to the index, the position of it will be altered by the moving of the index along the arch. The rays of an observed object are received on the speculum, and from thence reflected on one of the horizon glasses F, G, which are two small pieces of looking-glass placed on one of the limbs, their faces being turned obliquely to the speculum, from whence they receive the reflected rays of observed objects. This glass, F, has only its lower part quicksilvered, and set in brass-work; the upper part being left transparent to view the horizon. The glass G has in its middle a transparent slit, through which the horizon is to be seen. And because the warping of the wood-work, and other accidents, may distend them from their true situation, there are three screws passing thro' their feet, whereby they may be easily replaced. The screens are two pieces of coloured glass, set in two square brass frames K, K, which serve as screens to take off the glare of the sun's rays, which would be otherwise too strong for the eye; the one is tinged much deeper than the other, and, as both of them move on the same center, they may be both or either of them used: in the situation they appear in the figure, they serve for the horizon-glass F; but, when they are wanted for the horizon-glass G, they must be taken from their present situation, and placed on the quadrant above G.

The sight vanes are two pins, H and I, standing at right angles to the plane of the instrument; that at H has one hole in it, opposite to the transparent slit in the horizon-glass G; the other, at I, has two holes in it, the one opposite to the middle of the transparent part of the horizon-glass F, the other rather lower than the quicksilvered part: this vane has a piece of brass on the back of it, which moves round a center, and serves to cover either of the holes.

There are two sorts of observations to be made with this instrument; the one, when the back of the observer is turned towards the object, and therefore called the back-observation; the other, when the face of the observer is towards the object, which is called the fore-observation. To rectify the instrument for the fore-observation: slacken the screw in the middle of the

handle behind the glass F; bring the index close to the button *b*; hold the instrument in a vertical position, with the arch downwards; look through the right hand hole in the vane I, and through the transparent part of the glass F, for the horizon; and if it lies in the same right line with the image of the horizon, seen on the quicksilvered part, the glass F is rightly adjusted; but, if the two horizon-lines disagree, turn the screw at the end of the handle backwards or forwards, until those lines coincide, then fasten the middle screw of the handle, and the glass is rightly adjusted.

To take the sun's altitude by the fore-observation: having fixed the screens above the horizon-glass F, and suited them proportionally to the strength of the sun's rays, turn your face towards the sun, holding the instrument with your right hand, by the braces L, M, in a vertical position, with the arch downwards; put your eye close to the right hand hole in the vane I, and view the horizon through the transparent part of the horizon-glass F, moving at the same time the index D, with your left hand, till the reflex solar spot coincides with the line of the horizon; then the degrees counted from C, or that end next your body, will give the altitude of the sun at that time, observing to add or subtract 16 min. according as the upper or lower edge of the sun's reflex image is made use of. But to obtain the sun's meridian altitude, which is the thing wanted, in order to find the latitude; the observations must be continued, and, as the sun approaches the meridian, the index D must be continually moved towards B, in order to maintain the coincidence between the reflex solar spot and the horizon; and consequently, as long as this motion can maintain the same coincidence, the observation must be continued, and when the sun has attained the meridian, and begins to descend, the coincidence will require a retrograde motion of the index, or towards C; and then is the observation finished, and the degrees counted, as before, will give the sun's meridian altitude, or those from B, the zenith-distance.

6. *Sutton's*, sometimes called *Collins's Pocket QUADRANT*, as represented *fig. 6.* is a stereographic projection of one quarter of the sphere, between the tropics, upon the plane of the ecliptic, the eye being in its north pole; it is fitted to the latitude of London. The lines, running from the right hand to the left, are parallels of altitude; and those crossing them are azimuths. The lesser of the two circles, bounding the projection, is one fourth of the tropic of Capricorn; the greater is one fourth of that of Cancer. The two ecliptics are drawn from a point on the left edge of the quadrant, with the characters of the signs upon them; and the two horizons are drawn from the same point. The limb is divided both into degrees and time; and, by having the sun's altitude, the hour of the day may be found here to a minute.

The quadrantal arches next the center contain the calendar of months; and under them, in another arch, is the sun's declination.

On the projection are placed several of the most noted fixed stars between the tropics; and the next below the projection is the quadrant and line of shadows.

To find the time of the sun's rising or setting, his amplitude, his azimuth, hour of the day, &c. by this quadrant: lay the thread over the day and the month, and bring the bead to the proper ecliptic, either of summer or winter, according to the season, which is called rectifying; then, moving the thread, bring the bead to the horizon, in which case the thread will cut the limb in the time of the sun's rising or setting, before or after six; and at the same time the bead will cut the horizon in the degrees of the sun's amplitude.

Again, observing the sun's altitude with the quadrant, and supposing it found 45° on the 5th of May, lay the thread over the fifth of May, bring the bead to the summer ecliptic, and carry it to the parallel of altitude 45° , in which case the thread will cut the limb at $55^\circ 15'$, and the hour will be seen among the hour-lines to be either 41' past nine in the morning, or 19' past two in the afternoon.

Lastly, the bead among the azimuths shews the sun's distance from the south $50^\circ 41'$.

But note, that if the sun's altitude be less than what it is at six o'clock, the operation must be performed among those parallels above the upper horizon; the bead being rectified to the winter ecliptic.

7. *Sinical QUADRANT* (*fig. 7.*) consists of several concentric quadrantal arches, divided into eight equal parts by radii, with parallel right lines crossing each other at right angles.

Now any one of the arches, as B C, may represent a quadrant of any great circle of the sphere, but is chiefly used for the horizon or meridian. If then B C be taken for a quadrant of the horizon, either of the sides, as A B, may represent the meridian; and the other side, A C, will represent a parallel, or line of east and west: and all the other lines, parallel to A B, will also be meridians; and all those parallel to A C, east and west lines or parallels.

Again, the eight spaces into which the arches are divided by the radii, represent the eight points of the compass in a quarter of the horizon; each containing $11^{\circ} 15'$.

The arch B C, is likewise divided into 90° , and each degree subdivided into $12'$, diagonal-wise.

To the center is fixed a thread, which, being laid over any degree of the quadrant, serves to divide the horizon.

If the sinical quadrant be taken for a fourth part of the meridian, one side thereof, A B, may be taken for the common radius of the meridian and equator; and then the other, A C, will be half the axis of the world. The degrees of the circumference, B C, will represent degrees of latitude, and the parallels to the side A B, assumed from every point of latitude to the axis A C, will be radii of the parallels of latitude, as likewise the sine complement of those latitudes.

Suppose then it be required to find the degrees of longitude contained in 83 of the lesser leagues, in the parallel of 48° ; lay the thread over 48° of latitude on the circumference, and count thence the 83 leagues, on A B beginning at A; this will terminate in H, allowing every small interval 4 leagues. Then tracing out the parallel H E, from the point H to the thread; the part A E of the thread shews that 125 greater or equinoctial leagues make $6^{\circ} 15'$; and therefore that the 83 lesser leagues A H, which make the difference of longitude of the course, and are equal to the radius of the parallel H E, make $6^{\circ} 15'$ of the said parallel.

If the ship sails an oblique course, such course, besides the north and south greater leagues, gives lesser leagues easterly and westerly, to be reduced to degrees of longitude of the equator. But these leagues being made neither on the parallel of departure, nor on that of arrival, but in all the intermediate ones; we must find a mean proportional parallel between them.

To find this, we have on the instrument a scale of cross latitudes. Suppose then it were required to find a mean parallel between the parallels of 40° and 60° ; with your compasses take the middle between the 40th and 60th degree on the scale; this middle point will terminate against the 51st degree, which is the mean parallel required.

The principal use of the sinical quadrant is to form triangles upon, similar to those made by a ship's way, with the meridians and parallels; the sides of which triangles are measured by the equal intervals between the concentric quadrants, and the lines N and S. E and W; and every fifth line and arch is made deeper than the rest.

Now suppose a ship to have sailed 150 leagues north-east, one fourth north, which is the third point, and makes an angle of $33^{\circ} 45'$ with the north-part of the meridian: here are given the course and distance sailed, by which a triangle may be formed on the instrument, similar to that made by the ship's course; and hence the unknown parts of the triangle may be found. Thus supposing the center A to represent the place of departure; count, by means of the concentric circles, along the point the ship sailed on, viz. A D, 150 leagues from A to D; then is the point D the place the ship is arrived at, which note. This done, let D E be parallel to the side; and then there will be formed a right-angled triangle A E D, similar to that of the ship's course difference of longitude and latitude: the side A E gives 125 leagues for the difference of the latitude northwards,

which makes $6^{\circ} 15'$; and the side D E gives 83 lesser leagues answering to the parallels, which, being reduced as shewn above, gives the difference of the longitude. And thus is the whole triangle formed.

8. *Gunner's QUADRANT* (*fig. 8.*) sometimes called gunner's square, is that used for elevating and pointing cannon, mortars, &c. and consists of two branches either of brass or wood, between which is a quadrantal arch divided into 90° , beginning from the shorter branch, and furnished with a thread and plummet, as represented in the plate above referred to.

The use of the gunner's quadrant is extremely easy; for if the longest branch be placed in the mouth of the piece, and it be elevated till the plummet cut the degree necessary to hit a proposed object, the thing is done.

Sometimes on one of the surfaces of the long branch, are noted the division of diameters, and weights of iron-bullets, as also the bores of pieces.

QUADRANT of Altitude, (plate CVII. *fig. 9.*) is an appendage of the artificial globe, consisting of a lamina, or slip of brass, the length of a quadrant of one of the great circles of the globe, and graduated. At the end, where the division terminates, is a nut riveted on, and furnished with a screw, by means whereof the instrument is fitted on to the meridian, and moveable round upon the rivet, to all points of the horizon, as represented in the figure referred to.

Its use is to serve as a scale in measuring of altitudes, amplitudes, azimuths, &c. See *GLOBE*.

QUADRANTAL, in Roman antiquity, a vessel every way square like a die, serving as a measure of liquids. Its capacity was eighty libræ or pounds of water, which made forty-eight sextaries, two urnæ, or eight congi.

QUADRANTAL TRIANGLE, a spherical triangle, one of whose sides at least is a quadrant of a circle, and one of its angles a right angle. See *TRIANGLE*.

QUADRAT, *Quadratum*, a mathematical instrument, called also a geometrical square, and line of shadows: it is frequently an additional member on the face of the common quadrant, as also on those of Gunter's and Sutton's quadrant.

QUADRAT, in printing, a piece of metal cast like the letters, to fill up the void spaces between words, &c. There are quadrats of different sizes, as m quadrats, n quadrats, &c. which are, respectively, of the dimensions of these letters.

QUADRATIC Equation, in algebra, is that which involves one unknown quantity, and, at the same time, involves the square of that quantity and the product of it multiplied by some known quantity. — This kind of equations may be resolved by the following rule:

1. Transpose all the terms that involve the unknown quantity to one side, and the known terms to the other side of the equation.

2. If the square of the unknown quantity is multiplied by any coefficient, you are to divide all the terms by that coefficient, that the coefficient of the square of the unknown quantity may be an unit.

3. Add to both sides the square of half the coefficient prefixed to the unknown quantity itself, and the side of the equation, that involves the unknown quantity, will then be a complete square.

4. Extract the square root from both sides of the equation, which you will find, on one side, always to be the unknown quantity with half the foresaid coefficient subjoined to it; so that by transposing this half, you may obtain the value of the unknown quantity expressed in known terms.

Thus, suppose $y^2 + 2ay = b$,

Add the square of a to both sides of the equation, we have $yy + 2ay + aa = b + aa$; extract the root, $y + a =$

$\sqrt{b + a^2}$. Transpose a , and $y = \sqrt{b + a^2} - a$.

Let $y^2 - 2ay = b$, then $y^2 - 2ay + a^2 = b + a^2$, and $y - a =$

$\sqrt{b + a^2}$; hence $y = \sqrt{b + a^2} + a$.

Let $2ay - y^2 = b$, then $y^2 - 2ay = -b$, and by adding the square of a to both sides, we have $y^2 - 2ay + aa = aa - b$, and $y - a = \pm \sqrt{aa - b}$.

The square root of any quantity, as $+aa$, may be $+a$ or $-a$, and hence all quadratic equations admit of two solutions. In the first example, after finding that $y^2 + 2ay + aa = b + aa$, it may be inferred, that $y + a = \sqrt{b + a^2}$, or to $-\sqrt{b + a^2}$; since $-\sqrt{b + a^2} \times +\sqrt{b + a^2}$ gives $b + a^2$, as well as $+\sqrt{b + a^2} \times +\sqrt{b + a^2}$. There are, therefore, two values of y ; the one gives $y = +\sqrt{b + a^2} - a$, the other $y = -\sqrt{b + a^2} - a$.

Since the square of all quantities is positive, it is plain, that the square root of a negative quantity is imaginary, and cannot be assigned. Therefore there are some quadratic equations that cannot have any solution. For example:

Suppose $y^2 - 2ay + 3a^2 = 0$.

Then $y^2 - 2ay = -3a^2$.

Add a^2 to both, $y^2 - 2ay + a^2 = -3a^2 + a^2 = -2a^2$.

Extract the root $y - a = \pm \sqrt{-2a^2}$, and $y = a \pm \sqrt{-2a^2}$.

Whence the two values of y must be imaginary or impossible, because the root of $-2a^2$ cannot possibly be assigned.

QUADRATING of a Piece, among gunners, is the due placing of a piece of ordnance, and poising it in its carriage, and having its wheels of an equal height, &c. See **GUNNERY**.

QUADRATRIX, in geometry, a mechanical line, by means whereof we can find right lines equal to the circumference of circles, or other curves, and their several parts.

QUADRATRIX of Dinoftrates, so called from its inventor Dinoftrates, is a curve, whereby the quadrature of the circle is effected mechanically.

QUADRATRIX Tschirnhausiana, is a transcendental curve invented by M. Tschirnhausen, whereby the quadrature of the circle is likewise effected.

QUADRATURE, *Quadratura*, in geometry, the art of squaring, or reducing a figure to a square. See **CIRCLE**, **CURVE**, **FLUXIONS**, **SERIES**, &c.

QUADRATURE, in astronomy, that aspect of the moon when she is 90° distant from the sun; or when she is in a middle point of her orbit, between the points of conjunction and opposition, namely, in the first and third quarters. See **MOON**.

QUADRATURE-LINES, are two lines placed on Gunter's sector: they are marked with Q. and 5, 6, 7, 8, 9, 10: of which Q. signifies the side of the square, and the other figures the sides of polygons of 5, 6, 7, &c. sides. S, on the same instrument, stands for the semi-diameter of a circle, and 90 for a line equal to 90° in circumference.

QUADRATUS, in anatomy, a name given to several muscles, on account of their square figure.

QUADREL, in building, a kind of artificial stone, so called from its being perfectly square.

The quadrels are made of a chalky earth, &c. and dried in the shade for two years. These were formerly in great request among the Italian architects.

QUADRILATERAL, in geometry, a figure whose perimeter consists of four right lines, making four angles; whence it is also called a quadrangular figure. The quadrilateral figures are either a parallelogram, trapezium, rectangle, square, rhombus, or rhomboides.

QUADRUPEDS, *quadrupedia*, in zoology, a class of land-animals, with hairy bodies, and four limbs or legs proceeding from the trunk of their bodies: add to this, that the females of this class are viviparous, or bring forth their young alive, and nourish them with milk from their teats.

This class, though still numerous enough, will be considerably lessened in number, by throwing out of it the frog, lizard, and other four-footed amphibious animals. See **AMPHIBIOUS**.

On the other hand, it will be increased by the admission of the bat; which, from its having the fore-feet webbed with a membrane, and using them as birds do their wings in flying, has erroneously been ranked among the bird-kind.

Linnaeus subdivides the quadruped-class into six orders, which characterizes from the number, figure,

and disposition of their teeth. The first order he calls anthropomorpha, from their resemblance to the human shape: these have four fore-teeth in each jaw. The feræ, or beasts of prey, make the second order, and are distinguished by having six sharp-pointed fore-teeth in each jaw, and very long canine teeth. The third order, denominated agriæ, is sufficiently distinguished by having no teeth at all. The glires make the fourth class, and are distinguished by having the fore-teeth only two in number, and those prominent. The pecora constitute the fifth order, and have no fore-teeth at all in the upper jaw, and the fore-teeth in the lower jaw are six. The sixth and last order is that of the jumenta, the teeth of which are few in number, and disposed in an irregular manner, quite different from that of the five preceding orders.

QUADRUPLE, a sum or number multiplied by four, or taken four times.

This word is particularly used for a gold coin, worth four times as much as that of which it is the quadruple.

QUÆSTUS, in law, signifies whatever a person has by purchase; as hereditas denotes that which one has by descent, or hereditary right.

QUAKERS, a religious sect which made its first appearance in England during the interregnum; so called, in derision, from certain unusual tremblings with which they were seized at their first meetings. Their founder was George Fox, a shoemaker, born at Drayton, in Leicestershire; who, as he worked at his trade, used to meditate much on the scriptures: at length he began to see visions, and set up for a preacher. He proposed but few articles of faith, insisting chiefly on moral virtue, mutual charity, the love of God, and a deep attention to the inward motions and secret operations of the spirit. He required a plain simple worship, and a religion without ceremonies, making it a principal point to wait in profound silence the directions of the Holy Spirit.

Quakers were at first guilty of some extravagances, but these wore off, and they settled into a regular body, professing great austerity of behaviour, a singular probity and uprightness in their dealings, a great frugality at their tables, and a remarkable plainness and simplicity in their dress.

The system of the Quakers is laid down in fifteen theses, by Robert Barclay, in a sensible, well wrote apology, addressed to Charles II. Their principal doctrines are, That God has given to all men, without exception, supernatural light, which being obeyed can save them; and that this light is Christ, the true light, which lighteth every man that cometh into the world: that the scriptures were indeed given by inspiration, and are preferable to all the other writings in the world; but that they are no more than secondary rules of faith and practice, in subordination to the light or spirit of God, which is the primary rule: that immediate revelation is not ceased, a measure of the spirit being given to every one: that all superstitions and ceremonies in religion of mere human institution, ought to be laid aside: as also, in civil society, the saluting one another by pulling off the hat, bowing, or the like; and the saying *you* instead of *thou*, to a single person: that men and women ought to be plain and grave in their apparel, sober and just in their whole conversation, and at a word in all their dealings; and not to swear, to go to war, to fight in private quarrels, or even to bear any carnal weapons. They also entirely set aside the two sacraments, baptism and the Lord's supper; admit no clergy among them, but any one, without distinction, who is of a sober life, and believes him or herself to be moved thereto by the spirit, is allowed to preach in their assemblies; and they hold it unlawful to pay tythes, or church-rates. In short, they are a quiet inoffensive people, of exemplary morals, remarkably charitable and friendly to each other, and have never yet been guilty of persecution, though they have had it in their power.

As to discipline and polity, the affairs of the community are managed in their assemblies, of which there are several kinds; as monthly, quarterly, yearly, second days meetings, and meetings of sufferings. The monthly and quarterly meetings are held in their respective counties, to which deputies are sent from the several particular

particular meetings, and enquiry is made into the state of each meeting; who violate the laws of the community; who pay tythes or church-rates, and who suffer for the non-payment of either: here too they excommunicate, and receive again into their communion. Of all which registers are kept.

From these meetings appeals lie to their yearly assemblies, which are always held in London, and consist of three orders or classes; representatives sent from the quarterly meetings, correspondents from foreign countries and the several counties, and preachers. Hither are transmitted accounts of what has been transacted in all the monthly and quarterly meetings: here measures are concerted, and directions given as to behaviour about tythes, rates, &c. and here they compose differences and make provision for the poor: here public accounts are audited, and instructions given to the deputies to be observed at their return; and from hence a yearly epistle of admonition is dispatched to be read in all the monthly and quarterly meetings.

The second day's meeting is a standing committee, consisting of the principal preachers in and about the city, who meet every Monday to consider of particular cases and exigencies which happen between the yearly meeting.

The meetings of sufferings is held every week, and consists of the correspondents for each county. Its business is to receive complaints for such as have suffered for non-payment of tythes and church-rates, and to procure them relief, either by sending them money, for which they have a settled fund, or by soliciting their cause, or both.

QUALITY, *Qualitas*, is defined by Mr. Locke, to be the power in a subject of producing any idea in the mind: thus a snow-ball having the power to produce in us the ideas of white, cold, and round, these powers, as they are in the snow ball, he calls qualities; and as they are sensations, or perceptions, in our understandings, he calls ideas. See **IDEA**.

These qualities, according to the same philosopher, are of two sorts; first, original or primary qualities, are those inseparable from body, and such as it keeps in all its changes and situations: these are solidity, extension, motion or rest, number and figure: thus, take a grain of wheat, divide it into two parts, each has solidity, extension, figure, mobility; divide it again and it still retains the same qualities, and will do so still, though you divide it on till the parts become insensible. Secondly, secondary qualities are such, whatever reality we by mistake may attribute to them, as in truth are nothing in the objects themselves, but powers to produce various sensations in us, and depend on the qualities before-mentioned; such are colours, smells, tastes, sounds, &c.

The ideas of primary qualities of bodies, are resemblances of them, and their patterns really exist in bodies; but the ideas produced in us by secondary qualities have no resemblance of them at all: and what is sweet, blue, or warm, in the idea, is but the certain bulk, figure, and motion of the insensible parts in the bodies themselves which we call so: thus we see that fire at one distance produces in us the sensation of warmth, which at a nearer approach causes the sensation of pain. Now what reason have we to say that the idea of warmth is actually in the fire, but that of pain not in the fire, which the same fire produces in us the same way. The bulk, number, figure, and motion of the parts are really in it whether we perceive them or no, and therefore may be called real qualities, because they really exist in that body; but light and heat are no more really in it than pain or sickness: take away the sensation of them, let not the eyes see light or colours, nor the ear hear sounds, let the palate not taste, or the nose smell, and all colours, tastes, odours, and sounds, as they are such particular ideas, vanish and cease, and are reduced to their causes, that is, bulk, motion, figure, &c. of parts.

These secondary qualities are of two sorts; first, immediately perceivable, which by immediately acting on our bodies, produce several different ideas in us. Secondly, mediately perceivable, which, by operating on other bodies, change their primary qualities so as to render them capable of producing ideas in us different from what they did before. These last are powers in bodies,

which proceed from the particular constitutions of those primary and original qualities, to make such a change in the bulk, figure, texture, &c. of another body, as to make it operate on our senses differently from what it did before; as in fire, to make lead fluid: these two last being nothing but powers relating to other bodies, and resulting from the different modifications of the original qualities, are yet otherwise thought of; the former being esteemed real qualities, but the latter barely powers. The reason of this mistake seems to be this, that our ideas of sensible qualities, containing nothing in them of bulk, figure, &c. we cannot think them the effect of those primary qualities, which appear not to our senses to operate in their productions, and with which they have not any apparent congruity; nor can reason shew how bodies, by their bulk, figure, &c. should produce in the mind the ideas of warm, yellow, &c. but in the other case, when bodies operate upon one another, we plainly see that the quality produced hath commonly no resemblance with aught in the thing producing it, and therefore we look upon it as the effect of power: but our senses not being able to discover any unlikeness between the idea produced in us, and the quality of the object producing it, we imagine that our ideas are resemblances of something in the objects, and not the effects of certain powers placed in the modification of the primary qualities, with which primary qualities the ideas produced in us have no resemblance.

Secondary qualities, for the most part, serve to distinguish substances; for our senses fail us in the discovery of the bulk, figure, texture, &c. of the minute parts of bodies, on which their real constitutions and differences depend: and secondary qualities are nothing but powers with relation to our senses. The ideas that make our complex ones, of corporeal substances, are of three sorts: first, the ideas of primary qualities of things, which are discovered by our senses; such are bulk, figure, motion, &c. secondly, the sensible secondary qualities, which are nothing but powers to produce several ideas in us, by our senses; thirdly, the aptness we consider in any substance, to cause or receive such alterations of primary qualities, as that the substance, so altered, should produce in us different ideas from what it did before: and they are called active or passive powers. The mind can have no other idea of sensible qualities, than what comes from without, by the senses; nor any other idea of the operations of a thinking substance, than what it finds in itself; and as of two primary qualities of body, viz. solid coherent parts, and impulse, we have clear and distinct ideas, so likewise have we of two primary qualities of spirit, viz. thinking and a power of action: and as we have clear and distinct ideas of several qualities inherent in bodies, which are but the various modifications of the extension of cohering solid parts, and their motion; so we have likewise the ideas of the several modes of thinking, viz. believing, doubting, hoping, fearing, &c.

Chemical QUALITIES, those qualities principally introduced by means of chemical experiments, as fumigation, amalgamation, cupellation, volatilization, precipitation, &c.

QUALITY is also used for a kind of title given to certain persons, in regard of their territories, signories, or other pretensions.

QUANTITY, *quantitas*, any thing capable of estimation, or mensuration; or which, being compared with another thing of the same kind, may be said to be greater or less than it, equal or unequal to it.

Mathematics is the science or doctrine of quantity, which being made up of parts, is capable of being made greater or less. It is increased by addition, and diminished by subtraction; which are therefore the two primary operations that relate to quantity. Hence it is that any quantity may be supposed to enter into algebraic computations two different ways, which have contrary effects, viz. either as an increment or as a decrement. See the article **ADDITION** and **SUBTRACTION**.

As addition and subtraction are opposite, or an increment is opposite to a decrement; there is an analogous opposition between the affections of quantities that are considered in the mathematical sciences; as between ex-

cess and defect, between the value of effects or money due to a man, and money due by him; a line drawn towards the right, and a line drawn towards the left; gravity, and levity; elevation above the horizon, and depression below it. When two quantities equal in respect of magnitude, but of those opposite kinds, are joined together, and conceived to take place in the same subject, they destroy each other's effect, and their amount is nothing. A power is sustained by an equal power, acting on the same body with a contrary direction, and neither have effect. When two unequal quantities of those opposite qualities are joined in the same subject, the greater prevails by their difference; and when a greater quantity is taken from a lesser of the same kind, the remainder becomes of the opposite kind. When two powers or forces are to be added together, their sum acts upon the body; but when we are to subtract one of them from the other, we conceive that which is to be subtracted, to be a power with an opposite direction; and if it be greater than the other, it will prevail by the difference. This change of quality only takes place where the quantity is of such a nature as to admit of such a contrariety or opposition. We know nothing analogous to it in quantity abstractly considered, and cannot subtract a greater quantity of matter from a lesser; or a greater quantity of light from a lesser; and the application of this doctrine to any art or science, is to be derived from the known principles of the science.

A quantity that is to be added, is called a positive quantity; and a quantity to be subtracted, is said to be negative.

Quantities are said to be like or similar, that are of the same denomination, or are represented by the same letter or letters, equally repeated: but quantities of different denominations, or represented by a different letter or letters, are said to be unlike or dissimilar. A quantity consisting of more than one term is called a compound quantity; whereas that consisting of one term only is denominated a simple quantity.

The quantity of matter in any body, is the product of its density into its bulk; or a quantity arising from the joint consideration of its magnitude and density; as, if a body be twice as dense, and take up twice as much space as another, it will be four times as great. This quantity of matter is best discoverable by the absolute weight of bodies. See GRAVITY.

The quantity of motion in any body is the factum of the velocity into the mass, or it is a measure arising from the joint consideration of the quantity of matter, and the velocity of the motion of the body; the motion of any whole being the sum or aggregate of the motion in all its several parts. Hence, in a body twice as great as another, moved with an equal velocity, the quantity of motion is double; if the velocity be double also, the quantity of motion will be quadruple. Hence, the quantity of motion is the same with what we call the momentum or impetus of a moving body.

Combination of QUANTITIES. See the article COMBINATION.

Commensurable QUANTITIES. See the article COMMENSURABLE.

Exponential QUANTITY. See the article EXPONENTIAL.

Infinite QUANTITIES. See INFINITE Quantities and INFINITESIMALS.

Transcendental QUANTITIES. See the article TRANSCENDENTAL.

Variable QUANTITIES. See VARIABLE.

QUANTITY, in grammar, an affection of a syllable, whereby its measure, or the time wherein it is pronounced, is ascertained; or that which determines the syllable to be long or short.

QUANTITY is also the object of prosody, and distinguishes verse from prose; and the œconomy and arrangement of quantities, that is, the distribution of long and short syllables, makes what we call the number.

The quantities are used to be distinguished, among grammarians, by the characters $\cup$, short, as $p\bar{e}r$; and $-$, long, as $r\bar{o}s$. There is also a common, variable, or dubious quantity; that is, syllables that are one time taken for short ones, and at another time for long ones,

as the first syllable in *Atlas, patres*, &c. Feet are made up of quantities. See FOOT.

The quantity of a syllable is either natural or accidental: natural quantity is that taken from the nature of the vowel, as *re* in *refylo* is short, and *de* in *depello* is long. Accidental quantity is that departing from the natural quantity, merely by accident, as *re* in *refiti* is long, because it is immediately followed by two consonants; and *de* in *deamo* is short, because it immediately precedes a vowel.

The quantity of syllables is known two ways. 1. By rules for that purpose. And, 2. By authority. The rules for this end are taught by that part of grammar called prosody; the authority made use of in this case is no more than examples from, or the testimony of, approved authors; and is never used but either when the rules are deficient, or when we are unacquainted with them. The quantity of the syllables is but little fixed in the modern tongues; and there is still less regard had to it in the composition of modern verses. The want of feet, or rather the shortness and uniformity of our feet, makes a world of difference between the numbers of the antient and modern verse. The antients subsisted by their quantities alone; so well were they distinguished, and such a harmony did they produce. Our quantities make such poor music, that we are generally forced to call in the Gothic aid of rhyme, to distinguish our verse from prose.

QUARANTAIN, QUARENTINE, or QUARANTENA, in old law books, denotes the space of forty days. It also signifies a benefit allowed to the widow of a man dying seized of lands, &c. by which she may challenge to continue in his capital messuage, or chief mansion-house, so it be not a castle, for the space of forty days after his decease. And if the heir or any other person eject her, she may have the writ de quarantena habenda.

QUARANTAIN is more particularly used for a term of forty days, which vessels, coming from places suspected of contagion, are obliged to wait in certain places appointed to air themselves, before they come into port. See the article LAZAR-HOUSE.

QUARREL, *Querela*, in law, is generally applied to personal and mixed actions in which the plaintiff is called querens: and hence it is that if a person release all quarrels, it is taken to be as beneficial to the releasee, as if it were a release of all actions; since all actions both real and personal are thereby released.

QUARRY, a place under ground, out of which are got marble, free-stone, slate, lime-stone, or other matters proper for buildings.

Quarries of free-stone are in many places opened, and the stone brought out, in the following manner: they first dig a hole in the manner of a well, twelve or fourteen feet in diameter, and the rubbish drawn out with a windlass in large osier baskets, they heap up all around; placing their wheel, which is to draw up their stones, upon it. As the hole advances, and their common ladder becomes too short, they apply a particular ladder for the purpose. When they have got through the earth, and are arrived at the first bank or stratum; they begin to apply their wheel and baskets to discharge the stones as fast as they dig through them. In freeing the stone from the bed, they proceed thus: as common stones, at least the softer kinds, have two grains, a cleaving grain, running parallel with the horizon, and a breaking grain, running perpendicular thereto; they observe by the grain where it will cleave, and there drive in a number of wedges, till they have cleft it from the rest of the rock. This done they proceed to break it; in order to which applying the ruler to it, they strike a line, and by this cut a channel with their stone-ax; and in the channel if the stone be three or four feet long, set five or six wedges, driving them in very carefully with gentle blows, and still keeping them equally forward. Having thus broken the stone in length, which they are able to do of any size within half an inch, they apply a square to the straight side, strike a line, and proceed to break it in breadth. This way of managing stone is found vastly preferable to that where they are broken at random: one load of the former being found to do the business of a load and a half of the latter. But it may be observed, that this cleaving

grain being generally wanting in the harder kinds of stones, to break up these in the quarries, they have great heavy stone-axes, with which they work down a deep channel into the stone; and into this channel, at the top, lay two iron bars between which they drive their iron wedges.

Some in dividing the stone, especially the very hard kinds, make use of gunpowder, with very good effect. In order to which, making a small perforation pretty deep in the body of the rock, so as to have that thickness of rock over it judged proper to be blown up at once, at the further end of the perforation they dispose a convenient quantity of gunpowder, filling up all the rest with stones and rubbish, strongly rammed in, except a small place for the train. By this means is the rock blown into several pieces, most of which are not too big to be managed by the workmen.

QUARRY, or QUARREL, among glaziers, a pane or piece of glass cut in a diamond form.

Both words are derived from the French *quarré*, a square.

QUART, a measure containing the fourth part of some other measure. See the article MEASURE.

The English quart is the fourth part of a gallon, or two pints.

QUARTAN, *Quartana*, in medicine, a species of intermitting fever, wherein the patient has two fits in four days, or two days quite free from a fit.

It usually begins about four or five in the afternoon, sometimes sooner and sometimes later, with a great lassitude, stretching, a blunt pain in the head, back, loins, and legs; the feet and hands are cold, and the whole body is pale; and the face and nails livid, to which shivering and shaking supervene. The tongue and the lips tremble; the breathing is difficult, with restlessness, and tossing; the pulse is contracted and hard, and sometimes unequal; and there is an anxiety about the præcordia. These symptoms continue about two or three hours; and in some the body is costive, whereas in others there is a stimulus to stool, and to make water; in some again, there is a nausea or vomiting, with stools; and some advanced in years, have their minds pretty much disturbed. The heat comes on gradually, not burning but dry; the pulse becomes equal, quick, and large, but the dull pain in the head remains, with a vertiginous affection; the skin becomes only a little moist; and in about four or six hours, the symptoms vanish except a dull pain in the bones, joints, and feet. The urine in the fit is sometimes thin and watery, and sometimes thick with a sediment.

From the experiments of Dr. Langrish it appears, that the blood is more dense and tenacious in quotidians than in tertians, and in tertians than in quartans. See QUOTIDIAN and TERTIAN.

As to the cure, a vomit should be given after the first fit, in the time of intermission: in tender constitutions, ipecacuanha may be given alone, or two ounces of vinum ipecacuanhum; but to the more robust, a grain or two of emetic tartar may be added, to be taken in warm water about two hours after the paroxysm. The evacuation should be facilitated by taking large draughts of water-gruel made fat with fresh butter. Then take the following electuary, which will crush the disease in the bud: viz. take of rob of elder, one ounce; of Peruvian bark, five drams; of the powder of common chamomile-flowers, two drams; of the extract of lesser centaury and powder of clove-julyflowers, each half a dram; and as much syrup of lemons as is sufficient to reduce them to the form of an electuary. The dose is half a dram, to be taken every two hours after the fit.

If any thing forbids vomiting, the cure must be begun with deterfive and aperient salts, as vitriolated tartar, sal ammoniac, purified nitre, and crab's eyes; and if the ague still continue notwithstanding the repeated use of these salts, then an equal weight of Peruvian bark must be added to them, or the above electuary may be given.

When the patient is subject to the hypochondriac passion, the stomach is inflated, and the body costive; then neither vomits nor salts must be ventured upon, but carminative and emollient clysters.

In obstinate quartans, Hoffman greatly commends the following medicine: take of Peruvian bark, three drams; of medicinal regulus of antimony, two drams; of mercurius dulcis, which is not to be triturated with the powder, on account of the salts, but only mixed with the point of a knife, of the finest crocus martis, and of vitriolated nitre, each one dram; and of oil of mint, four drops: make up all these into a powder, of which half a dram, or a dram, may be taken, made into the form of a bolus with rob of elder, and syrup of clove-julyflowers.

This method is confirmed by Huxham, who says the bark frequently proves ineffectual, without the help of proper alexipharmics; as snake-root of Virginia, contrayerva, myrrh, camphor, &c. After four or five paroxysms, warm chalybeates may be added with very great success; but when the patient's complexion has a yellow cast, and he has a tense abdomen, and very costive habit of body, mercurial, saponaceous deobstruents with rhubarb, aloetics, or sal diureticus should be premised to, or joined with the bark. Hoffman observes, that obstinate quartans in boys are not to be cured but by purging; and therefore, he directs the following form: take of cream of tartar, one dram; of calx of antimony, twelve grains; of sulphurated diagrydium, six grains; make them into a powder, which may be taken in three doses, the first six hours before the fit, the second before the next fit, and the third before the third fit. After this, he orders an infusion of half an ounce of Peruvian bark in eight ounces of fennel-water; adding the bark of eleutherius, sal diureticus, and salt of tartar, of each one dram, together with half an ounce of syrup of clove-julyflowers; a spoonful of which should be taken every two hours.

To prevent the return of an ague, the bark must be repeated every week or ten days, for three several times, with the same intervals. Likewise bitters and chalybeates are very serviceable, taken either together or separately.

QUARTATION, in metallurgy, a method of purifying gold, by melting three parts of silver with one of gold, and then throwing the mixture into aqua-fortis.

Experience has taught us, says Cramer, that aqua-fortis dissolves silver mixed with gold quickly enough, when the gold constitutes but one, and the silver three parts of a mixed mass of them: and in this case, if the solution is not too impetuously performed, the gold usually remains in such a proportion, in the same figure that the whole mass had before the separation of the silver by this menstruum; so that in this case, there is no reason to apprehend the gold's being torn into minute particles, and dissipated in some measure, though this can hardly be prevented when the silver exceeds the three quarter proportion, in regard to the gold in the mass. The artificers therefore, always make it their study to observe very exactly this proportion of the gold being one fourth part of the mixture; and thence it is that the operation itself has been called quartation.

From this operation we may learn how fallacious the examination made with aqua-fortis alone of the gold rubbed on the touchstone, must necessarily prove.

QUARTER, *Quadrans*, the fourth part of any thing, the fractional expression for which is $\frac{1}{4}$.

QUARTER, in weights, is generally used for the fourth part of an hundred weight averdupois, or 28 lb.

Used as the name of a dry measure, quarter is the fourth part of a ton in weight, or eight bushels.

QUARTER, in law, the fourth part of a year; and hence the days on which these quarters commence, are, March 25, called Lady-Day; June 24, or Midsummer-day; September 29, or Michaelmas; and December 21, or St. Thomas the Apostle's day. On these days rents on leases, &c. are usually reserved to be paid; though December 25, or Christmas-day, is commonly reckoned the last quarter-day.

QUARTER, in astronomy, the fourth part of the moon's period: thus, from the new moon to the quadrature is the first quarter; from this to full moon, the second quarter, &c.

QUARTER, in heraldry, is applied to the parts or members

members of the first division of a coat that is quartered, or divided into four quarters.

Franc-Quarter, in heraldry, is a quarter single or alone; which is to possess one fourth part of the field.

This makes one of the honourable ordinaries of a coat.

Quarter of a Point, in navigation, is the fourth part of the distance between two cardinal points, which is $2^{\circ} 48'$.

Quarter, the hinder part of a ship's side, or that part of the side which is nearest the stern, commencing nearly from the mizen chains, and terminated by the fashion-pieces on the edge of the stern. See *FASHION-PIECE*, *CHAINS*, and *MIZEN*.

Quarter also implies the middle of a yard-arm, or that part of a yard-arm on each side which is about half-way from the mast to either of the ends or extremes of the yards.

Quarter-cloth, a long piece of canvas painted with trophies, and other ornamental figures of war, and extended along the upper-side of a ship's quarter.

Quarter-deck is the deck that reaches over all the hind-parts of a ship, where the principal officers walk, as on a parade. Above the after-part of this deck is placed the poop, which commonly forms the captain's cabin in a large ship of war, when the one below it, his usual habitation, is occupied by an admiral or commodore.

Quarter-gallery, a sort of railed balcony projecting over a ship's quarter, close to the stern.

Quarter gunners, certain officers under the command of the gunner of a ship of war, to keep the artillery, ammunition, &c. in good order.

Quarter-master, an officer who walks the quarter-deck of a ship of war to watch the man at the helm, and observe that the ship is properly steered, to keep the time regularly by watch-glasses, to remark what boats come on board, and to assist at stowing and unstowing the hold.

Quarter-netting, a sort of net-work extending from the quarter-rail to the gunnel, which is drawn extremely tight.

Quarter-rail, a rail extended along the quarters on each side, immediately above the gunnel, or upper-part of the side.

Quarter tackle is a tackle, or complication of pulleys hung from the quarter of the yard, to hoist any thing into or out of the ship.

Quartering wind, one that blows on the quarter, which is the fairest direction possible.

Quarters, the stations of the officers and men of a vessel of war, in the time of engagement; and hence the posting them to their several stations is called, quartering the crew.

Quarter, in the military art, is used in various senses, as for the place allotted to a body of troops to encamp upon: thus they say, The general has extended his quarters a great way, &c. *Quarter* also signifies the sparing mens lives: thus it is said, The enemy asked quarter; We gave no quarter.

Quarter of an Assembly, is the place of rendezvous, where the troops are to meet, and draw up in a body.

Head Quarters, is the place where the general of an army has his quarters, which is generally near the center of the army.

Quarters of Refreshment, is the place to which the troops that have been much fatigued are sent to refresh themselves during a part of the campaign.

Winter Quarters, the places in which the troops are lodged during the winter, or their residence in those places.

Quarter-master, an officer in the army, whose business is to look after the quarters of the soldiers; of which there are several kinds, viz. The quarter-master general, whose business is to provide good quarters for the whole army. Quarter-master of horse, he who is to provide quarters for a troop of horse. Quarter-master of foot, he who is to provide quarters for a regiment of foot,

Quarter, in the manege, as to work from quarter to quarter, is to ride a horse three times in upon the first of the four lines of a square; then changing your hand, to ride him three times upon the second; and so to third and fourth; always changing hands and observing the same order.

Quarters, with respect to the parts of a horse, is used in various senses: thus the shoulders and fore-legs are called the fore-quarters, and the hips and hinder-legs, the hind quarters. The quarters of a horse's foot, are the sides of the coffin, comprehending between the toe and the heel; the inner quarters, are those opposite to one another, facing from one foot to the other; and these are always weaker than the outside quarters, which lie on the external sides of the coffin. False quarters are a cleft in the horn of a horse's hoof, extending from the coronet to the shoe. A horse is said to be quarter-cast, when for any disorder in the coffin we are obliged to cut one of the quarters of the hoof.

Quarter-chord, in mining, is seven yards and a quarter, which the miner has cross-ways of his vein, on either side, for liberty to lay his earth, stones, and rubbish on, and to wash and dress up his ore.

Quarters, in building, are those slight upright pieces of timber placed between the puncheons and posts, used to lath upon.

These are of two sorts, single and double; the single quarters are sawn to two inches thick, and four inches broad; the double quarters are sawn to four inches square. It is a rule in carpentry, that no quarters be placed at a greater distance than fourteen inches.

Quarter-round, in architecture, is a term used by the workmen for any projecting moulding in general whose contour is a perfect quadrant of a circle, or which approaches near that figure.

Quarter-sessions, a general court held quarterly by the justices of peace of each county. See *JUSTICES of Peace*.

Quarter-wheeling, or *Quarter of Conversion*, in the military art, is the motion by which the front of a body of men is turned round to where the flank was, by taking a quarter of a circle. If it be done to the right, the man in the right-hand angle keeps his ground and faces about, while the rest wheel; if to the left, the left-hand man keeps his place.

Quartering, in gunnery, is when a piece of ordnance is so traversed that it will shoot on the same line, or on the same point of the compass as the ship's quarter bears.

Quartering, in heraldry, is dividing a coat into four or more quarters, or quarterings, by parting, coupling, &c. that is, by perpendicular and horizontal lines, &c.

Counter Quartering a coat, is when the quarters are subdivided each into four.

There are counter-quartered coats that have twenty or twenty-five quarters.

Quarterly, in heraldry. A person is said to bear quarterly, when he bears arms quartered.

Quartern, a diminutive of quart, signifying a quarter of a pint.

Quarto, or *4to*, a book of which four leaves, or eight pages, make a sheet.

Quarto-Decimans, *Quarto-Decimani*, an antient christian sect, so called from their maintaining that the festival of Easter ought to be celebrated conformably to the custom of the Jews, on the fourteenth day of the moon in the month of March, whatever day of the month that happened to be.

Quashing, in law, the overthrowing and annulling of any thing.

Quaver, in music, a measure of time equal to half a crotchet, or an eighth of a semibreve.

The quaver is divided into two semi-quavers, and four demi-semi-quavers.

Quavering, in music, trilling or shaking; or the running a division with the voice.

Quay, or *Kay*. See the article *WHARF*.

Queen, *Regina*, denotes either a woman who holds the crown of a realm, singly and by right of blood called queen

queen regnant; or it is a title, by way of courtesy, given to her that is married to the king, and called queen consort; or the widow of a king is called queen, but with the addition of dowager. In the first sense, queen is the same with king, and has the same power and prerogative.

QUEEN-BEE, a name given by late writers to what used to be called the king-bee, or king of the bees; a large and long-bodied bee, of which kind there is only one found in every swarm, and which is always treated with the greatest respect by the rest. See the article BEE.

QUEEN Gold, *Aurum Reginae*, a royal revenue, belonging to the queen of England, during her marriage to the king, and payable, upon several grants of the king, by way of oblation, out of fines, amounting to one full tenth part above the entire fine, or ten pounds for every hundred pounds fine, on pardons, contracts, or agreements.

QUE ESTATE, in law, a plea whereby a man intitling himself to land, &c. saith that the same estate which another had, he now has from him.

QUE EST MEME, in law, is used in actions of trespass, &c. for a direct justification of the very act complained of by the plaintiff as a wrong.

QUERELA, QUARREL. See the article QUARREL.

QUESTION, QUESTIO, in logic, &c. a proposition whose truth a person being inquisitive about, proposes it by way of interrogation to another.

QUEST, or INQUEST, an inquisition made upon oath of an inpanelled jury.

QUEST MEN, persons chosen yearly in each ward in London, &c. to enquire into abuses, especially such as relate to weights and measures.

QUESTOR, *Quæstor*, an officer in ancient Rome who had the care of the public treasure.

The questor's office, questorship, *quæstura*, was originally confined to the army. They paid the soldiery, took charge of monies accruing by spoil, plunder, &c. At length new ones were erected to reside in the city, and receive the public money, &c.

There were also another kind of questors whose office was to enquire into, and take cognizance of, capital crimes.

QUESTOR *Sacri Palatii*, or Questor of the sacred palace, was one of the first dignities under the emperors of Constantinople. He subscribed the receipts, and the answers to petitions presented to the emperor: he drew up and signed the laws, and took care of the administration of justice.

QUEUE, in heraldry, denotes the tail of the beast. If a lion have a forked tail, he is blazoned double queued.

QUEUE *d'aronde*, in fortification, denotes any outworks which are narrower at the gorge than the face or front.

Of this kind there are some single as well as double tenailles, and some horn-works, whose sides are not parallel.

On the contrary, when the sides are less than the gorge, the work is called *contre queue d'aronde*.

QUICKSILVER, a very ponderous fluid mineral, the same as mercury. See the article MERCURY.

QUICK, or QUICKSET-HEDGE, among gardeners, denotes all live hedges, of whatever sort of plants they are composed, to distinguish them from dead hedges; but, in a more strict sense of this word, it is applied to the hawthorn, or *mespilus sylvestris*: under which name the young plants, or sets, are commonly sold by the nursery gardeners, who raise them for sale.

In the choice of these sets, those which are raised in the nursery are to be preferred to such as are drawn out of the woods: because the latter have seldom good roots; though, as they are larger plants than are commonly to be had in the nursery, many people prefer them on that account: but from long experience I have found, that those hedges which have been planted with young plants from the nursery, have always made the best hedges. Indeed, if persons would have patience to wait for their from seed, and to sow the haws in the place where the hedge is designed, these unremoved plants will make a much stronger and more durable fence, than those which

are transplanted: but I am aware that most people will be for condemning this practice, as being tedious in raising; but, if the haws are buried one year in the ground, to prepare them for vegetation, before they are sown, it will not be so long before this will become a good fence, as is generally imagined. Nay, from some trials of this kind, which I have made, I have found, that those plants which have remained where they came up from seed, have made such progress as to overtake, in six years, plants of two years growth, which were transplanted at the time when these seeds were sown.

And, if the hedges are raised from seed, it will not be amiss to mix holly berries with the haws, and, if so, these berries should also be buried one year, to prepare them, so that then both will come up together the following spring; and this mixture of holly with the quick will not only have a beautiful appearance in the winter, but will also thicken the hedge at the bottom, and make it a better fence.

But, where the hedge is to be planted, the sets should not be more than three years old from the haws; for, when they are older, their roots will be hard and woody; and, as these are commonly trimmed off before the sets are planted, so they very often miscarry; and such of them as do live, will not make so good progress as younger plants, nor are they so durable; for these plants will not bear transplanting so well as many others, especially when they have stood long in the seed-bed unremoved. *Miller's Gard. Diet.*

QUID, WHAT, in the schools, denotes a definition: so called, as answering to the question *Quid est?* what is it?

Hence we have two kinds, as nominal, *quid nominis*, and real, *quid rei*.

QUIDDITY, *quidditas*, in the schools, the essence or nature of a thing known or expressed in any definition.

And hence, whatever is essential to a thing, is said to be quiddative.

QUIESCENT denotes any thing at rest, in contradistinction to motion.

QUIETISM, the sentiments of the Quietists, a religious sect which made a great noise towards the close of the last century.

Molinos, a Spanish priest, who died at Rome in the prison of the inquisition, passes for the author of Quietism; and yet the Illuminati in Spain had taught something like it before.

The name is taken from a sort of absolute rest, and inaction, which the soul is supposed to be in, when arrived at the state of perfection, which in their language is called the unitive lief.—To arrive at this, a man is first to pass through the purgative way; that is, through a course of obedience, inspired by the fear of hell: hence, he is to proceed into the illuminative way, before he arrive at perfection; to go through cruel combats, and violent pains, i. e. not only the usual drudgeries of the soul, and the common privations of grace, but infernal pains: he believes himself damned; and the persuasion that he is so, continues upon him very strongly several years: St. Francis des Sales, say the Quietists, was so fully convinced thereof, that he would not allow any body to contradict him therein.—But the man is, at length, sufficiently paid for all this, by the embraces of God, and his own deification.

These sentiments of the Quietists, with regard to God, are wonderfully pure and disinterested.—They love him for himself, on account of his own perfections, independently of any rewards or punishments: the soul acquiesces in the will of God, even at the time when he precipitates it into hell; insomuch that, instead of stopping him on this occasion, B. Angelo de Foligny cried out, 'Haste, Lord, to cast me into hell: do not delay, if thou hast abandoned me, but finish my destruction, and plunge me into the abyss.'

At length, the soul, after long travail, enters into rest, into a perfect quietude.—Here it is wholly employed in contemplating its God; it acts no more, thinks no more, desires no more; but lies perfectly open, and at large, to receive the grace of God, who by means thereof drives it where it will, and as he will.

In this state, it no longer needs prayers or hymns, or vows; prayers where the spirit labours, and the mouth opens, are the lot of the weak and the imperfect: the soul of the saint is, as it were, laid in the bosom, and between the arms of its God, where, without making any motion, or exerting any action, it waits, and receives the divine graces. — It, then, becomes happy: quitting the existence it before had, it is now changed, it is transformed, and, as it were, sunk and swallowed up in the Divine Being, insomuch as not to know or perceive its being distinguished from God himself. *Penel. Max. des Saints.*

QUILLS, the large feathers taken out of the end of the wing of a goose, crow, &c.

Quills are denominated from the order in which they are fixed in the wing, the second and third quills being the best for writing, as they have the largest and roundest barrels. Crow-quills are chiefly used for drawing. In order to harden a quill that is soft, thrust the barrel into hot ashes, stirring it till it is soft, then taking it out, press it almost flat upon your knee with the back of a pen-knife, and afterwards reduce it to a roundness with your fingers. If you have a number to harden, set water and alum over the fire, and while it is boiling put in a handful of quills, the barrels only, for a minute, and then lay them by.

QUILT, a covering for a bed, formed of two pieces of silk, cotton, &c. quilted together.

QUILTING, a method of sewing two pieces of silk, linnen, or stuff on each other, with wool or cotton between them; by working them all over in the form of chequer or diamond-work, or in flowers. The same name is also given to the stuff so worked.

QUILTING, amongst sailors, the act of weaving a sort of coat or matting round a jar or jug to prevent it from breaking.

QUINCUNX, **QUINQUE UNCIÆ**, denotes five twelfth parts of any thing.

QUNCUNX, in gardening, a disposition of trees originally formed into a square, consisting of five trees, one at each corner, and a fifth in the middle; which disposition, repeated again and again, forms a regular grove, and then viewed by an angle of the square or parallelogram presents equal and parallel alleys.

Or the quincunx is the disposition of trees in several rows, both length and breadthwise; so that the first tree of the second row commences in the center of the square formed by the two first trees of the first row, and the two first of the third, resembling the figure of a five in cards.

The modern quincunxes, Daviler observes, are made like those of the ancients, except for the fifth tree, which is now generally disused; so that being netted, and their alleys viewed by the side of the rectangle, they form a perfect chequer.

QUINCUNX, in astronomy, &c. denotes an aspect of the planets, when distant from each other one hundred and fifty degrees, or five signs.

QUINDECAGON, or rather pentecagon, in geometry, a plain figure which has fifteen sides, and as many angles.

The word is compounded of the Latin *quindecim*, fifteen, and the Greek *γωνία*, angle.

If the sides be all equal, it is a regular quindecagon. The side of such a quindecagon inscribed in a circle, by Eucl. prop. 16. l. 3. is equal in power to the half difference between the side of the equilateral triangle and the side of the pentagon, as also to the difference of the perpendiculars let fall on both sides taken together.

QUINQUAGENARIUS, among the Romans, was an officer in the army who had the command of a company of fifty men.

There was also an officer of policy so called, who had the inspection of fifty houses or families.

QUINQUAGESIMA SUNDAY, Shrove-Sunday; so called, as being about the fiftieth day before Easter.

QUINQUINA, in pharmacy, the name of a very useful medicine called also Peruvian bark; it being the bark of a tree growing in Peru.

The tree producing this bark is of a middling size, called by the Spaniards, from its efficacy against inter-

mitting fevers, *palo de calenturas*, or the fever tree. This virtue of the bark is said to have been discovered by the Indians about the year 1500, but not revealed to their European masters till 140 years after; when a signal cure having been performed by it on the Spanish viceroy's lady, the countess del Cinchon, it came into general use in those parts, and was distinguished by the appellations *pulvis comitissæ*, *cortex china china* or *chinchina*, *kina kina* or *kinkina*, and *quina quina*, or *quinquina*. In 1649 a Jesuit brought a large quantity of it into Italy, which was distributed by the fathers of that order, at a great price, in different parts of Europe: about the same time a quantity was purchased by cardinal de Lugo for the use of the poor at Rome. From these it received the names of *cortex* or *pulvis Jesuiticus*, *pulvis patrum*, and *pulvis cardinalis de Lugo*.

This bark is brought to us in pieces of different sizes, some rolled up into short thick quills, and others flat: the outside is brownish, and generally covered in part with a whitish moss: the inside is of a yellowish, reddish, or rusty iron colour. The best sort breaks close and smooth, and proves friable betwixt the teeth: the inferior kinds appear when broken of a woody texture, and in chewing separate into fibres. The former pulverizes more easily than the latter, and looks, when powdered, of a light brownish colour, resembling that of cinnamon, but somewhat paler.

A bark was some time ago brought from America under the name of the female Peruvian bark. This was found, from experience, to be less effectual as a medicine than the genuine sort, which it was frequently substituted to or mixed with in France, insomuch that its importation, as the editor of Geoffroy informs us, was prohibited by law. It is considerably thicker, whiter on the out side, redder within, and weaker in smell and taste than the true bark.

Peruvian bark has a slight smell, approaching as it were to mustiness, yet so much of the aromatic kind as not to be disagreeable. Its taste is considerably bitter, astringent, very durable in the mouth, and accompanied with some degree of aromatic warmth, but not sufficient to prevent its being ungrateful.

The febrifuge virtue, for which alone this medicine was at first recommended, has now been established by the daily experience of about a century: and that, when judiciously and seasonably administered, it proves as safe as it is effectual, is now also beyond dispute. An emetic, which is in most cases necessary, being taken towards the approach of a paroxysm, that its operation may be over before the fit comes on; the bark is begun at the end of the paroxysm, or even in the time of the hot fit, and repeated, in doses of half a dram or more, every third or fourth hour, during the intermission: after the fever has been removed, the medicine is continued for a time, but more sparingly, to prevent a return. During the use of the bark, the pulse, which betwixt the paroxysms is generally weak and slow, becomes stronger and quicker, the appetite mends, the patient grows more chearful, and perspiration increases: these may be looked upon as sure presages of its success. At first it frequently occasions a looseness, and this also is salutary; but if the purging runs on too long, as the fever rarely yields while this evacuation continues, it is usually checked by the addition of a little opium: if too great costiveness ensues, recourse is had to clysters. In gross impure habits, gentle purgatives are premised to the bark, or given for a time in conjunction with it: in agues of the inflammatory kind, or accompanied with a great heat, a little nitre is joined or interposed: in lax spongy constitutions, and a thin watery state of the blood, the bark is assisted by bitters, snakeroot, camphor, and chalybeates: — where obstructions of the abdominal viscera are apprehended, it is not ventured on without the addition of fixed alkaline salts, sal ammoniac, or other aperients. In all cases, moderate exercise, and the drinking of warm liquids, promote its effects.

In remitting fevers, this medicine is less successful than in those which have perfect intermissions: in hectic, or wherever pus is formed, or juices extravasated, it does harm. In the decline of long nervous fevers, or after a remission, and in those of the low malignant

nant kind, where the blood is colliquated and the strength exhausted, it proves an excellent cordial, corroborant, and antiseptic.

Peruvian bark has likewise been found serviceable in gangrenes and mortifications, and in foul obstinate ulcers and running sores of other kinds; in these cases, taken in large and repeated doses, it frequently brings on a laudable suppuration, which degenerates on discontinuing the use of the medicine, and again turns kindly upon resuming it. The like effects have been observed from it in variolous cases, where either the pustules did not duly suppurate, or petechiæ shewed a disposition to a gangrene: by the use of the bark, the empty vesicles filled with matter, watery sanies changed into thick white pus, and the petechiæ became gradually paler, and at length disappeared. The principal symptom in this disease that contraindicates this valuably suppurant and antiseptic, is great obstruction at the breast or difficulty of breathing; which are always by this medicine increased, insomuch that small doses have in some cases endangered suffocation.

In tumours of the glands, the Peruvian bark appears to promote not suppuration, but resolution. In the Medical Observations and Inquiries published by a society of physicians in London, there are several instances of its being given with success in scrophulous complaints. Dr. Fothergill observes, that inveterate ophthalmiæ generally yield to it: that beginning glandular tumours are very frequently resolved, and their farther progress stopt by it: that swelled lips, cutaneous blotches arising from a like cause, are healed, and the tendency to a strumous habit corrected: that it does not succeed in all cases, but there are few in which a trial can be attended with much detriment: that he has never known it to avail where the bones were affected, or where the scrophulous tumour was so situated as to be attended with much pain, as in the joints, or under the membranous covers of the muscles; for when it attacks these parts, the periosteum, and consequently the bone, seldom escape being injured; that here the bark, instead of lessening, adds to the fever which accompanies these circumstances, and if it does not increase the force of the mischief, seems at least to hasten its progress.

Peruvian bark has been applied likewise, in conjunction with other appropriated medicines, and often with good success, to the cure of periodic head-achs, hysterical, hypochondriacal, vertiginous and epileptic complaints, and other disorders that have regular intermissions. By its bitterness, astringency, and mild aromatic warmth, it strengthens the whole system, and proves a medicine of great utility in weakness of the stomach, uterine fluxes, and sundry chronical diseases proceeding from a laxity and debility of the fibres. To strengthen the solids appears indeed, in all cases, to be its primary operation; and its salutary virtues in different diseases, to be no other than consequential effects of this general power. In all the distempers where bark is known to take place, other astringent and bitter medicines, singly or combined, have likewise been of service, though not equally with this natural combination of them.

The virtues of this bark are very difficultly extracted by long coction in water, and part of what the liquor is by heat enabled to take up begins to separate as soon as it is cold. This resinous part, which is rather melted out by the boiling heat than dissolved by the water as a menstruum, seems to contain chiefly the astringency of the drug; the bitter matter appears to be perfectly dissoluble, though more difficult to be got completely out.

On boiling a pound of powdered bark for an hour or two in five or six quarts of water, the decoction whilst hot looks clear and reddish, but in cooling becomes turbid, and of a pale yellowish or wheyish hue: in this state it is found to partake, in a great degree, both of the bitterness and astringency of the bark; but in proportion as it deposits the matter that made it turbid, it loses more and more of its stypticity, the bitterness seeming to continue undiminished. The remaining bark, boiled in fresh water, exhibits the same appearances for two or three times successively; and when, at length, it ceases to render the water turbid, it imparts a bitterness without astringency, retaining still some share of bitterness

itself. The vapour which exhales in the first coction, being caught in proper vessels, condenses into a limpid liquor which smells strongly of the bark; though no separable oil is obtained on submitting many pounds to the operation. The several decoctions, strained and inspissated together, yield an extract, rather less bitter, and much less styptic, than the bark in substance: this extract is kept in the shops in a soft and a hard form; the one of a proper consistence for making into pills, the other fit for being reduced into powder.

As decoctions of bark lose of their virtue in being made fine by settling and colature, they are generally directed to be taken turbid; only the grosser parts of the powder being separated by passing them through a sieve. This form does not appear to be superior, in elegance, any more than in efficacy, to draughts with the bark in substance: a mixture of a fine powder with infusion of liquorice and a little of any grateful aromatic water, is far more palatable than the turbid decoction. Among all the materials I have tried for covering the taste of the bark, liquorice, or its extract, were found to answer the purpose most effectually, whether in a liquid form or in that of an electuary.

As this drug gives out its virtue so difficultly and imperfectly to boiling water, it has not been suspected that cold water would have any considerable action on it: I have nevertheless found, that an infusion in cold water is rather stronger in taste than even the turbid decoction, though the latter has somewhat more of a kind of fulness in the mouth. It is by means of a gummy matter in vegetables, that the resinous parts become dissoluble in watery liquors; and it seems probable that, in boiling, part of the gummy principle of the bark is hastily dissolved and disunited from the resinous, whereas cold water, acting more gradually, extracts them both together. The cold infusions strike a black colour with chalybeate solutions; which I have not observed any of the decoctions to do, at least in any considerable degree, whether turbid or transparent; a proof that the former contain the astringent matter of the bark in a perfectly dissolved state, and the latter not. I have given the infusions in intermitting fevers as well as other disorders, with all the success that could have been expected from any preparation of this valuable medicine: the proportions commonly followed were, one ounce of the powdered bark and eight or twelve of water, which were macerated without heat for twenty-four hours, and the clear liquor given in doses of two or three ounces.

It is a common opinion, that bark in substance is more effectual than any preparation of it. Thus much is plain, that the infusions, as well as the decoctions, have not near so much effect as the quantity of bark they were made from, as the menstruum does not in either case completely extract its active matter: but their effects are evidently the same in kind, and the difference in degree may be compensated by an increase in the quantity.

The turbid decoctions, on the addition of any of the concentrated mineral acids, in the proportion of one drop to about a quarter of an ounce, become transparent, of a bright pale yellow colour, and of a rougher or more acerb taste, but with the loss of their bitterness: the vegetable acids, added in a proportionably larger quantity, render them likewise transparent, and improve their roughness, without much diminishing their bitterness: all these mixtures deposite, on standing, a little powdery sediment. Alkalies, both fixed and volatile, occasion a more copious precipitation, and instead of making the turbid decoctions clear, make the clear turbid.

Rectified spirit receives from bark a deep reddish brown colour, and takes up much more of its active matter than watery liquors: by digesting the powder first in some rectified spirit, and then boiling it in water, nearly the whole of its virtue is pretty readily got out. In inspissating the filtered tincture, the spirit carries off nothing remarkable of its smell or taste: the remaining extract retains the peculiar flavour of the bark, as well as its astringency and bitterness, and proves a very elegant preparation from the tincture by water, as having the resinous part somewhat divided by an admixture of the gummy. The spirituous tincture, and the decoction of the residuum, may be united into an extract, possessing this advantage

vantage in a greater degree, by inspissating them separately to the consistence of a syrup, then mixing them together, and continuing the evaporation with a gentle heat.

Proof spirit extracts less from bark than rectified spirit, but more than water. Four ounces of the powder, macerated for some hours without heat, in a quart of proof spirit, impart a considerable degree both of bitterness and astringency: on applying heat, the taste becomes stronger, the colour darker, and the liquor somewhat turbid; from whence it may be concluded, that the resinous part is not by this menstruum completely dissolved.

Spirit of sal ammoniac made with fixed alkaline salt, by maceration with powdered bark in the above proportion, receives from it very little taste or colour. The spirit prepared with quicklime, and the dulcified spirit, extract in a few hours a very deep colour, and become strongly impregnated with its virtue. Though the spirit made with quicklime is held too acrimonious to be given internally by itself, it is not liable to that objection here; its pungency being sheathed by the substance which it dissolves. *Lewis's Materia Medica.*

QUINTAL, in commerce, a hundred pounds weight.

The quintal admits of some difference in different places, according as the pound consists of more or fewer ounces.

The English quintal usually consists of one hundred and twelve pounds avoirdupoise, and is divided into four quarters.

QUINTESSENCE, QUINTA ESSENTIA, in chemistry, a preparation consisting of the essential oil of some vegetable substance, incorporated with spirit of wine.

Of this there are two kinds, namely, liquid and dry: the former is produced by putting any distilled aromatic or essential oil into a clean dry glass, and pouring to it twelve times its quantity of pure alcohol distilled from alkali, so as not to contain the least water: shake them together, and the oil will intirely mix with the alcohol, so as to form one simple transparent liquor.

Dry quintessences are got by pouring alcohol, wherein an aromatic oil is dissolved, upon ten times its weight of dry loaf sugar, reduced to a fine powder. Grind them exactly together in a glass body, kept on all sides moderately warm, that the remaining spirit may gently exhale, and, by means of a still-head, be collected in the form of a liquid quintessence; and thus the sugar will remain dry, yet impregnated with the quintessence. Let this now be put immediately into a glass vessel close stopped, and preserved for use.

QUINTILE, QUINTILIS, in astronomy, an aspect of the planets, when they are 72 deg. distant from one another, or a fifth part of the zodiac.

QUINTILIANS, a sect of ancient heretics, thus called from their prophetess Quintilia. In this sect the women were admitted to perform the sacerdotal and episcopal functions. They attributed extraordinary gifts to Eve for having first eaten of the tree of knowledge; told great things of Mary the sister of Moses, as having been a prophetess, &c. They added, that Philip the deacon had four daughters, who were all prophetesses, and were of their sect. In these assemblies it was usual to see the virgins entering in white robes, personating prophetesses.

QUINZY, QUINSEY, or ANGINA, in medicine, a pain and inflammation of the fauces, a swelling of the uvula, tonsils, and larynx, which being accompanied with a fever, occasions a difficulty of respiration and deglutition. This disease generally prevails about the latter end of spring or beginning of summer. When the swelling, pain, and redness, appear mostly on the out-sides, it is, according to Hoffman, the prognostic of a happy solution of the disease: but when the external swelling suddenly disappears, without a mitigation of the symptoms, it shews the morbid matter to be translated elsewhere, and that the disease will change to a frenzy, or peripneumony. This disease may also terminate in a suppuration, gangrene, or schirrhous. A frothing at the mouth, the tongue vastly swelled, and of a purple, blackish colour, portend death.

The quinzy is generally distinguished by modern writers into the idiopathic and symptomatic. The first, where it is itself the disease, and owes its origin only to a plethora; the second, where it is but the accidental symptom of an inflammatory fever, or some other disease, about the time of its crisis.

Dr. Mead distinguishes the quinzy into three sorts; the first of which he calls the watery quinzy; the second, a gangrene of the tonsils; and the third, a strangulation of the fauces. In the first sort, the glands of the mouth, palate, and neighbouring parts are swollen. In the second, an inflammation without a perfect suppuration seizes the tonsils, which swell and grow hard; a gangrene soon ensues, which, if not speedily relieved, proves fatal.

In the third sort, all the nerves are convulsed, and the patient drops down dead suddenly: however, this species of quinzy, though described by Hippocrates, is yet very rare. If it can be foreseen, it ought to be prevented by evacuations of all kinds; that is, bleeding, purging, blistering, issues, and diuretics; and it will be of service to practise abstinence, or a moderation in eating and drinking. In the watery quinzy, which sometimes rages like an epidemic fever, especially in places near the sea, bleeding plentifully as soon as possible is recommended; afterwards clysters, gentle purges, blisters under the chin, and on the sides of the neck; and if this course does not succeed, the palate must be pretty deeply scarified about the tongue and sublingual veins.

In these inflammations in general, a slight diarrhoea relieves the patient, according to Arbuthnot. Therefore aliments which promote it are of service; such are tamarinds infused in whey, decoctions of farinaceous vegetables moderately acidulated, and such as abound with a cooling nitrous salt are useful. Burnet is said to be a specific in the quinzy; mulberries, and all acids are beneficial. The mouth and throat must be kept moist, and the nose clear, that the air may have a free passage through it. Sydenham orders to bleed plentifully in the arm, and Boerhaave directs it to be by a large orifice. Afterwards a sublingual vein should be opened; but, according to Hoffman, bleeding in the jugular yields the best assistance. If the symptoms continue to be very urgent, the bleeding may be repeated in six or eight hours time, till they begin to be more mild. After the first bleeding, Sydenham orders a strong and large blister to be laid to the neck: then let the parts inflamed be touched with the following mixture. Take honey of roses, as much as you please; and mix it with as much spirit of sulphur as is sufficient to give it the greatest sharpness. Afterwards the following gargle is to be held in the mouth till it is hot; and is to be repeated pretty often: take plantain-water, and frog-spawn, of each four ounces; red roses, four ounces; the whites of three eggs beat in water; and two drams of crystal sugar.

When the fauces are dry, hot, and the tongue swells; with difficulty of breathing and swallowing, Hoffman orders to take of the whites of eggs beat in water, two ounces; water of roses, one ounce; sal prunella, twelve grains; syrup of quinces, one ounce. Make a linctus, which is to be taken often; and let the neck be anointed as well behind as before with the following camphorated oil. Take of the oil of sweet almonds, one ounce; oil of white poppies, one dram; camphor, half a dram; after which let the patient take a cooling emulsion.

Boerhaave, after bleeding, orders a strong purge, and if that cannot be taken, a strong clyster. Emollient steams, or even the steam of hot water taken in at the mouth, is beneficial. If the patient is not able to swallow any nourishment, take of good broths of flesh-meat, ten ounces; nitre, ten grains; spirit of salt, six drops; make a clyster to be ejected every eight hours, and retained as long as is possible. Hoffman says, that if the tumour tends to a suppuration, it is best promoted by holding dried figs in the mouth, and that when the tonsils are full of an inflammatory ichor, honey of roses, mixt with spirit of vitriol, and often applied to the part with a pencil, is excellent. In a latent internal exceeding hot quinzy, the mouth must be frequently moistened with milk or cream, with an addition of sal prunella and syrup of poppies.

Dr.

Dr. Pringle observes, that the inflammatory quinzy is most frequent, as well as dangerous among soldiers, upon their first encampment; and that its tendency to bring on a suffocation, indicates the necessity of speedy and large bleedings, purging, and blistering. He also recommends the following application, as one of the most efficacious remedies in this terrible disorder: let a piece of thick flannel be moistened with equal parts of any common oil and of spirit of hartshorn, and applied to the throat, to be renewed once in four or five hours: this medicine, he tells us, he had from Dr. Young, physician in Edinburgh. By means of this application, the neck, and sometimes the whole body, is put into a sweat; which, after bleeding, either carries off or lessens the inflammation. He also tells us, that he has observed little benefit arising from gargles, and that the acid ones did more harm than good; however, a decoction of figs in milk and water, especially if the spirit of sal ammoniac be added, serves to thin the saliva, whereby the glands secrete more freely; a circumstance always conducive to the cure.

In the Philosophical Transactions, the jelly of black currants, swallowed down leisurely in small quantities, is asserted to be a specific for a quinzy; and a decoction of the leaves or bark in milk, when the jelly cannot be had, used as a gargle, is said to cure all the inflammatory distempers of the throat that happen in the winter time.

In malignant fevers, when there is an inflammation of the œsophagus, Hoffman orders to take nitre, one dram; camphor, three grains; sugar, one ounce; make a powder, which is to be given in an emulsion of sweet almonds, and may also be held in the mouth for some time before it is swallowed. That inflammatory pain which arises from a sharp salt serum in the glandulous parts of the fauces with redness and a copious flux of saliva, but without a fever, may be cured with a gargle of brandy alone. When there is a large defluxion of an impure serous humour upon the fauces, it requires a frequent use of gentle laxatives. When the symptoms of a quinzy are so urgent, that the patient is in immediate danger of strangling, recourse must be had to bronchotomy, or opening of the wind-pipe.

QUINK, in building, a piece of ground taken out of any regular ground-plot, or floor: thus if the ground-plot were oblong or square, a piece taken out of a corner to make a court or yard, &c. is called a quink.

QUIRE of paper, the quantity of twenty-four or twenty-five sheets.

QUIRISTER, or CHOIRISTER, a person appointed to sing in the choir of a cathedral.

QUIT-RENT, in law, a small rent that is payable by the tenants of most manors, whereby the tenant goes quit and free from all other services; and it is said to be an acknowledgement, in token of subjection to the

lord. Anciently this payment was called white rent, on account that it was paid in silver coin, and to distinguish it from rent-corn.

QUITTER-BONE, among farriers, the same with crotches. See CROTCHES.

QUOINS, in architecture, denote the corners of brick or stone walls. The word is particularly used for the stones in the corners of brick-buildings. When these stand out beyond the brick-work, their edges being chamfered off, they are called rustic quoins.

QUORUM, a word frequently mentioned in our statutes, and in commissions both of justices of the peace and others. It is thus called from the words of the commission, *quorum A. B. unum esse volumus*. For an example, where a commission is directed to seven persons, or to any three of them, whereof A. B. and C. D. are to be two; in this case, they are said to be of the quorum, because the rest cannot proceed without them: so a justice of the peace and quorum is one without whom the rest of the justices in some cases cannot proceed.

QUOTATION, in literature, a citation, or passage, rehearsed expressly in one author from another.

QUOTATIONS are usually distinguished by inverted commas.

QUOTIDIAN, *Quotidiana*, in medicine, an intermitting fever, or ague, the paroxysm or fit whereof returns every day.

This species of intermitting fevers is not so common as the tertian and quartan.

It attacks the patient early in the morning, with chillness and shivering; to which succeed a cardialgia, nausea, and inflation of the belly; in some a pain in the head, in others fainting fits, and in most vomiting or stools, or both; after which comes on the hot fit, with thirst.

As to the cure, the best method seems to be first to attenuate the tough and vitiated humours in the stomach and intestines, by proper doses of vitriolated tartar, and the like; after which a gentle emetic, diaphoretics and diuents are to be administered; and lastly, the bowels are to be strengthened by bitters and sub-astringents; among which, the Peruvian bark claims a place, only to be used in smaller quantities than when trusted to alone for the cure.

QUOTIENT, in arithmetic, the number which arises by dividing the dividend by the divisor. See DIVISION.

QUO WARRANTO, in law, a writ which lies against a person or corporation, that usurps any franchise or liberty against the king; as to have a fair, market, or the like, in order to oblige the usurper to shew by what right and title he holds or claims such franchise.

This writ also lies for mis-user, or non-user of privileges granted.

R.

R A B

R, a liquid consonant, and the seventeenth letter of the alphabet.

The grammarians hold it for a semi-vowel, especially in the Greek, where it admits an asperate.

The Hebrews allow it the privilege of a guttural, that is, they never double it, which yet is done by the Arabs, Greeks, Latins, &c.

Its sound is formed by a guttural extrusion of the breath, vibrated through the mouth, with a sort of quivering motion of the tongue drawn from the teeth, and cannulated with the tip a little elevated towards the palate.

It has but one sound, and is followed by an *h* in Greek words, as *rhapsody*, *rhetoric*, &c. otherwise it is always followed by a vowel at the beginning of words and syllables.

Used as a numeral, *R* anciently stood for 80, and with a dash over it, thus, *R̄*, 80,000; but the Greek *r*, or *ρ*, signified 100.

In the prescriptions of physicians, *R* or *R̄* stands for *recipe*, that is, take.

RABBETING, in carpentry, the planning, or cutting of channels or grooves in boards, &c.

In ship-carpentry, it signifies the letting in of the planks of the ship into the keel; which, in the rake and run of a ship, is hollowed away, that the planks may join the closer.

RABBI, or **RABBINS**, a title which the Pharisees and doctors of the law among the Jews assumed, and literally signifies masters or excellents.

There were several gradations before they arrived at the dignity of a rabbin, which was not conferred till they had acquired the profoundest knowledge of the law and the traditions. It does not however appear that there was any fixed age, or previous examination necessary; but when a man had distinguished himself by his skill in the written and oral law, and passed through the subordinate degrees, he was saluted a rabbin by the public voice.

Among the modern Jews, for near seven hundred years past, the learned men retain no other title than that of rabbi, or rabbins: they have great respect paid them, have the first places or seats in their synagogues, determine all matters of controversy, and frequently pronounce upon civil affairs: they have even a power to excommunicate the disobedient.

RABBINET, a small piece of ordnance, between a falconet and a base. See **CANNON**.

RABBINISTS, among the modern Jews, an appellation given to the doctrine of the Rabbins concerning traditions, in opposition to the Caraites, who reject all traditions.

RABBIT, *Cuniculus*, in zoology, a well known animal of the lepus, or hare kind, with a very short tail.

The female or doe rabbit goes with young thirty days, and then she kindles; and if she take not buck presently she loses her month, or at least a fortnight, and often kills her young and eats them.

R A B

In England they begin to breed at a year old, but in some places much sooner; and they continue breeding very fast from the time when they begin, four, five, six, or seven times a year being common with them. They have usually from four to seven in a litter, and hence it is that a small number at first will soon stock a whole warren, if left to breed a little while undisturbed. The does cannot suckle their young till they have been at buck again: this therefore is to be done presently, else there is a fortnight lost of the time for the next brood, and the present brood also probably lost. When the buck goes to the doe, he always beats and stamps very hard with his feet, and, when he has copulated with her, he falls backwards, and lies as it were in a trance; in this state it is easy to take him, but he soon recovers from it.

The buck rabbits, like our boar cats, will kill the young ones, if they can get at them; and the does in the warrens prevent this, by covering their stocks, or nests, with gravel or earth, which they close so artificially up with the hinder part of their bodies, that it is hard to find them out. They never suckle the young ones at any other time than early in the morning, and late at night, and always, for eight or ten days, close up the hole at the mouth of the nest, in this careful manner, when they go out. After this, they begin to leave a small opening, which they increase by degrees, till at length, when they are about three weeks old, the mouth of the hole is left wholly open, that they may go out: for they are at that time grown big enough to take care of themselves, and to feed on grass.

People who keep rabbits tame for profit, breed them in hutches, but these must be kept very neat and clean; otherwise they will be always subject to diseases. Care must be taken also to keep the bucks and does apart till the latter have just kindled, then they are to be turned to the bucks again, and to remain with them till they shun and run from them.

The general direction for the choosing of tame rabbits is, to pick the largest and fairest; but the breeder should remember that the skins of the silver-haired ones sell better than any other. The food of the tame rabbits may be colewort and cabbage leaves, carrots, parsnips, apple-rinds, green corn, and vetches, in the time of the year; also vine leaves, grass, fruit, oats, and oatmeal, milk-thistles, sow-thistles, and the like; but with these moist foods they must always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwise they will grow pot-bellied, and die. Bran and grains mixed together have been also found to be very good food. In winter they will eat hay, oats, and chaff, and these may be given them three times a day; but when they eat green things, it must be observed that they are not to drink at all, for it throws them into a dropy. At all other times a very little drink serves their turn, but that must always be fresh. When any green herbs or grass are cut for their food, care must be taken that there is no hemlock among it, for, though they will

eat this greedily among other things, when offered to them, yet it is sudden poison to them.

Rabbits are subject to two principal infirmities. First, the rot, which is caused by the giving them too large a quantity of greens, or from the giving them fresh gathered, with the dew or rain hanging in drops upon them. It is over moisture that always causes this disease; the greens therefore are always to be given dry, and a sufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moisture of their juices. On this account the very best food that can be given them, is the shortest and sweetest hay that can be got; of which one load will serve two hundred couples a year; and out of this stock of two hundred, two hundred more may be eat in the family, two hundred sold to the markets, and a sufficient number kept in case of accidents.

The other general disease of these creatures is a sort of madness: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner into their boxes. This distemper is supposed to be owing to the rankness of their feeding; and the general cure is the keeping them low, and giving them the prickly herb, called tare-thistle, to eat.

The general computation of males and females is, that one buck rabbit will serve for nine does; some allow ten to one buck, but those who go beyond this always suffer for it in their breed.

The wild rabbits are to be taken either by small cur dogs, or by spaniels bred up to the sport; and the place of hunting those who straggle from their burrows is under close hedges, or bushes, or among corn-fields and fresh pastures. The owners use to course them with small greyhounds, and, though they are seldom killed this way, yet they are driven back to their burrows, and are prevented from being a prey to others. The common method is by nets, called purse nets, and ferrets. The ferret is sent into a hole to force them out, and the purse net, being spread over the hole, takes them, as they come out. The ferret's mouth must be muffled, and then the rabbit gets no harm. For the more certain taking of them, it may not be improper to pitch up a hay net or two, at a small distance from the burrows that are intended to be hunted: thus very few of the number that are attempted will escape.

Some who have not ferrets smoak the rabbits out of their holes with burning brimstone and orpiment. This certainly brings them out into the nets, but then it is a very troublesome and offensive method, and is very detrimental to the place, as no rabbit will, of a long time, afterwards come near the burrows which have been fumed with these stinking ingredients.

RABBET, in ship-building, when a plank is to be fastened to any piece of timber, such as the stern or post, there is so much wood cut out of the piece as the plank is thick, which is called the rabbit; and when the plank is let into this rabbit it will be even with the outside of the piece, as at the after-end of the keel, and lower-end of the stern-post. *Murray's Ship-building.*

RACK, in the manege, a pace in which a horse neither trots nor ambles, but shuffles as it were between.

RACK is also a wooden frame made to hold hay or fodder for cattle.

RACK, an engine of torture, furnished with pullies and cords, &c. for extorting confessions from criminals.

RACK, ARAC, or ARRAC, in commerce, a spirituous liquor made by the Tartars of Tongusia, who are subject to the czarina of Muscovy. This kind of rack is made of mares-milk, which is left to be sour, and afterwards distilled twice or thrice between two earthen pots closely stopped, from whence the liquor runs through a small wooden pipe. This liquor is more intoxicating than brandy distilled from wine.

Rack is also a spirituous liquor which the English get from Batavia or Malacca, of which there are three sorts; the one being extracted from the cocoa-tree, the second from rice, and the third from sugar: but the first is the best and most in use. It is made of the blossom-bunch of the cocoa-tree; for which purpose they tie the bunch while it is still wrapped up within its cod, or membrane, with a piece of packthread, and then with a knife make

a cross cut in that bunch, a little above the place where it is tied, and adapt a pitcher to it to receive the liquor, which is called toddy, and is vinous, palatable, and sweet: others use a bamboe-cane instead of a pitcher. Having thus drawn the liquor, they let it ferment, and afterwards distil it.

Goa and Batavia are the chief places for rack. At Goa there are several kinds; single, double, and treble distilled; but the double distilled, which is that commonly sent abroad, is but a weak spirit when compared with Batavia rack; yet, on account of its peculiar and agreeable flavour, it is preferred to all the other racks of India. The Prior rack, made at Madras, the Columbo and Quilone rack, being fiery hot spirits, are but little valued by the Europeans, and therefore seldom imported, though they are highly prized among the natives.

To RACK wines, &c. to draw them off from their lees, after having stood long enough to clear and settle.

Hence rack-vintage is frequently used for the second voyage our wine-merchants used to make into France for racked-wines.

RACKET, a kind of bat to strike the ball with at tennis; usually consisting of a lattice or net-work of catgut strained very tight in a circle of wood, with a shaft or handle.

RACKET is also a kind of snow-shoe, or machine, which the savages of Canada bind to their feet, to enable them to walk more commodiously on the snow; made much in the manner of a tennis racket.

RACKING, or RAGGING, the tackles, in the sea language, the act of seizing or fastening two opposite parts of a pulley together, to prevent them from running through the blocks.

When a vessel rides in an open road or harbour, where it is apprehended the crew may seize the boats to desert, it is usual to hoist the boats up to the upper part of the ship's side in the evening, and to let them hang by the tackles all night. But lest any one through negligence should loosen the rope of the tackle, so as to let the boat, or one end of it, fall into the sea, the tackles are racked or tied together above the blocks.

RACKOON, *Coati*, in zoology, an American quadruped of the shape of a beaver, only somewhat smaller, and with the hair like that of a fox, only that the ears are shorter, roundish, and naked; its tail is longer than its body, and not unlike that of a cat, with annular streaks of different colours.

RADIAL CURVES, are curves of the spiral kind, whose ordinates, if they may be so called, all terminate in the center of the including circle, appearing like radii of that circle, whence the name. See the articles CURVE and SPIRAL.

RADIALIS, or RADIIÆUS, in anatomy, the name of two muscles of the arm, one of which, called radialis internus, is one of the three flexor muscles of the carpus, or hand, which arising from the internal condyle of the humerus, is inserted into the bone of the carpus next the thumb; and the other, called radialis externus, is one of the three extensor muscles of the hand, which arising from the external condyle of the humerus, is inserted into the first metacarpal bone.

RADIANT, or RADIATING POINT, in optics, is any point of a visible object, from whence rays proceed.

RADIATED FLOWERS, in botany, such as have several semi-flores round a disk, in form of a radiant star: those which have no such rays are called discous flowers.

The term radiated is also used with respect to one of the ancient crowns. See CROWN.

RADIATION, the act of a body emitting or diffusing rays of light all round, as from a center.

RADICAL, in general, something that serves as a basis or foundation.

In grammar, we give the appellation radical to primitive words, in contradistinction to compounds and derivatives.

Algebraists also speak of the radical sign of quantities, which is the character expressing their roots.

RADICLE, that part of the seeds of all plants, which upon vegetating becomes its root, and is discoverable by the microscope.

RADIOMETER, an instrument otherwise called the fore-staff. See **FORE-STAFF**.

RADISH, *Raphanus*, in botany, a genus of plants, the flower of which consists of four leaves, which are placed in form of a cross: out of the flower cup rises the pointal, which afterwards turns to a pod in form of an horn, that is thick, spongy, and furnished with a double row of roundish seeds, which are separated by a thin membrane.

There are several species of radish, but we shall only mention that which is commonly cultivated in kitchen-gardens for its root; of which there are several varieties, as the small-topped, the deep-red, and the long-topped striped radish; all which are varieties arising from culture. The small-topped sort is most commonly preferred by the gardeners near London, because they require much less room than those with large tops, and may be left much closer together; and, as the forward radishes are what produce the greatest profit to the gardener, so these being commonly sown upon borders near hedges, walls, or pales, if they are of the large-topped sort, they will be apt to grow mostly at top, and not swell so much in the root as the other, especially if they are left pretty close.

The seasons for sowing this seed are various, according to the time when they are desired for use; but the earliest season is commonly towards the latter end of October, that the gardeners near London sow them to supply the market; and these, if they do not miscarry, will be fit for use in March following, which is full as soon as most people care to eat them. These, as I said before, are commonly sown on warm borders, near walls, pales, or hedges, where they may be defended from the cold winds.

The second sowing is commonly about Christmas, provided the season be mild, and the ground in a fit condition to work: these are also sowed near shelter, but not so near pales and hedges as the first sowing. These, if they are not destroyed by frost, will be fit for use the beginning of April: but, in order to have a succession of these roots for the table through the season, you should repeat sowing of their seeds once a fortnight, from the middle of January till the beginning of April; always observing to sow the latter crops upon a moist soil and an open situation, otherwise they will run up, and grow sickly, before they are fit for use.

Many of the gardeners near London sow carrot-seed with their early radishes; so that many times, when their radishes are killed, the carrots will remain: for the seeds of carrots commonly lie in the ground five or six weeks before they come up, and the radishes seldom lie above a fortnight under-ground: so that these are often up, and killed, when the carrot seed remains safe in the ground: but, when both crops succeed, the radishes must be drawn off very young, otherwise the carrots will be drawn up so weak, as not to be able to support themselves, when the radishes are gone.

It is also a constant practice with the gardeners, to mix spinach-seed with their latter crop of radishes; so that, when the radishes are drawn off, and the ground cleaned between the spinach, it will grow prodigiously, and in a fortnight's time will as completely cover the ground, as though there had been no other crop. And this spinach, if it be of the broad-leaved kind, will be larger and fairer than it commonly is, when sown by itself; because, where people have no other crop mixed with it, they commonly sow it too thick, whereby it is drawn up weak; but here the roots stand pretty far apart, so that, after the radishes are gone, they will have full room to spread; and, if the soil be good, it is a prodigious size this spinach will grow to, before it runs up for seed: but this husbandry is chiefly practised by such gardeners as pay very dear for their land, and are obliged to have as many crops in a year as possible, otherwise they could not afford to pay such large rents.

When the radishes are come up, and have got five or six leaves, they must be pulled up where they are too close, otherwise they will draw up to top, but the roots will not increase their bulk. In doing of this, some only draw them out by hand: but the best method is to

hoe them with a small hoe, which will stir the ground and destroy the young weeds, and also promote the growth of the plants. The distance which they should be left, if for drawing up small, may be three inches; but, if they are to stand until they are pretty large, six inches are full near enough, and a small spot of ground will afford as many radishes at each sowing, as can be spent in a family, while they are good.

Horse **RADISH**, a well known plant, belonging to the genus cochlearia.

Horse radish is propagated by cuttings or buds from the sides of the old roots. The best season for this work is in October or February; the former for dry lands, and the latter for moist. The manner of doing it is as follows: Provide yourself with a good quantity of off-sets, which should have a bud upon their crowns; but it matters not how short they are: therefore, the upper part of the roots which are taken up for use, should be cut off about two inches long with the bud to it, which is esteemed the best for planting. Then make a trench ten inches deep, in which you should place the off-sets at about four or five inches distance each way, with the bud upward, covering them up with the mould that was taken out of the trench: then proceed to a second trench in like manner, and continue the same until the whole spot of ground is planted. After this, level the surface of the ground even, observing to keep it clear from weeds, until the plants are so far advanced, as to be strong enough to over-bear and keep them down. With this management, the roots of the horse radish will be long and straight, and free from small lateral roots; and the second year after planting will be fit for use. It is true, they may be taken up the first year, but then the roots will be but slender; therefore it is the better way to let them remain until the second year. The ground in which this is planted ought to be very rich, otherwise the roots will make but a small progress.

Radishes have the virtues of the scurvy grass; the root is esculent, expels phlegm from the intestines, and is a carminative. The flowers, leaves, seeds, and roots, are antiscorbutic; for which reason they are much in request, and are proper for phlegmatic constitutions: the expressed juice of the roots and seeds, taken in a morning with honey, is a very wholesome medicine, especially if a draught of whey be taken afterwards; for it cleanses the stomach, kidneys, and lungs, and is good against an inveterate cough and hoarseness, proceeding from phlegm; but it is not proper in a cough proceeding from an inflammation, nor for those who spit blood. The leaves are used among other greens. The root contains much of an acrimonious substance: and, the drier it is, the more acrid it becomes; but its acrimony is lost in boiling. Its aquosity renders it flatulent, on which account it is said not to be good in hypochondriacal disorders; the daily use of the root, however, is of sufficient efficacy to cure a great dropy in the beginning; and it is of excellent service in the scurvy. It is also aperitive, inciding, and good for the stone, the nephritic cholic, a retention of urine, and the menses, and in the jaundice. The seeds are opening; but taken inwardly by themselves, they excite a nausea. *Hist. Plant. ascript. Boerhaave.*

RADIUS, in geometry, the semi-diameter of a circle, or a right line drawn from the center to the circumference. See **CIRCLE**.

In trigonometry, the radius is termed the whole sine, or sine of 90°. See **SINE**.

RADIUS, in anatomy, the exterior bone of the arm, descending along with the ulna, from the elbow to the wrist.

RADIX, the same with root. See the article **ROOT**.

RAFT, amongst sailors, a sort of float consisting of a number of poles or planks, firmly tied together alongside of each other, to be conveyed to any distant place in a river, or to lade a ship.

In several roads of the Baltic sea the floats of timber, or planks, are towed to the ships in this manner.

RAFT-PORT, a large square port, or hole, cut thro' the buttock of a ship, under the counter, to receive the planks, or timber, which comes aboard on the raft. They are drawn into the ship thus longitudinally, because they

they cannot be let down through the hatches on account of their extreme length.

RAFTERS, in building, are pieces of timber, which standing by pairs on the reason or raising piece, meet in an angle at the top, and form the roof of a building. It is a rule in building that no rafters should stand farther than twelve inches from one another; and, as to their sizes or scantlings, it is provided by act of parliament, that principal rafters, from twelve feet six inches to fourteen feet six inches long, be five inches broad at the top and eight at the bottom, and six inches thick. Those from fourteen feet six inches to eighteen feet six inches long, to be nine inches broad at the foot, seven inches at the top, and seven inches thick; and those from eighteen feet six inches, to twenty-one feet six inches long, to be ten inches broad at the foot, eight at the top, and eight thick. Single rafters, eight feet in length, must have four inches and a half, and three inches three quarters in their square. Those of nine feet long must be five and four inches square.

Principal rafters should be nearly as thick at the bottom as the beam, and should diminish in their length one fifth or one sixth of their breadth; the king-posts should be as thick as the principal rafters, and their breadth according to the bigness of them that are intended to be let into them, the middle part being left somewhat broader than the thickness.

RAG, or **RAKE**, a company, or herd of young colts.

RAG-BOLT, in ship-building, a long cylindrical pin of iron to drive through the plank into the timbers on particular occasions; the inward end of it is ragged, or full of little barbs, to prevent them from drawing back by the working of the ship.

RAGULED, or **RAGGED**, in heraldry, jagged or knotted. This term is applied to a cross formed of the trunks of two trees without their branches, of which they shew only the stumps.

RAJA, the title of the Indian black princes, the remains of those who ruled there before the moguls.

RAIL, in architecture, denotes those pieces of timber which lie horizontally between the pannels of wainscot.

It is also applied to those pieces of timber which lie over and under ballusters in balconies, stair-cases, &c. as also from post to post in fences with pales or without.

RAILS, in ship-building, are narrow planks generally of fir, upon which there is a moulding struck. They are for ornament, and nailed across the stern above the wing-transom, and counters, &c. They are likewise nailed upon several planks along the sides; one in particular is called the sheet-rail, which limits the height of the side from the fore-castle to the quarter-deck, and run aft to the stern, and forward to the cat-head. The wales are nearly parallel to this. *Murray's Ship Building.*

There are also other rails above the deck, ranging fore and aft, to prevent the men from falling over into the sea. Such are the fifth-rail, quarter-rails, stern and fore-castle-rails. See the article **QUARTER**.

RAIN, a watery meteor, which descends from the clouds in form of drops of water.

Rain is apparently the precipitated vapours of watery clouds: thus, when various congeries of clouds are driven together by the agitation of the winds, they mix and run into one body, and by that means dissolve and condense each other into their former substance of water; also the coldness of the air is a great means to collect, compact, and condense clouds into water; which being heavier than the air, must of necessity fall through it in the form we call rain. Now the reason why it falls in drops, and not in whole quantities, as it becomes condensed, is the resistance of the air; whereby, being broken and divided into smaller and smaller parts, the farther it passes through the air, it at last arrives to us in small drops.

Mr. Derham accounts for the precipitation hence, that the vesiculæ being full of air, when they meet with a colder air than that they contain, their air is contracted into a less space; and, consequently, the watery shell rendered thicker, so as to become heavier than the air, &c.

Others only allow the cold a part in the action,

and bring in the winds as sharers with it: indeed, it is plain, that a wind, blowing against a cloud, will drive its vesiculæ upon one another, by which means several of them coalescing, will be enabled to descend; and the effect will be still more considerable if two opposite winds blow towards the same place. Add to this, that clouds already formed, happening to be aggravated by fresh accessions of vapour continually ascending, may thence be enabled to descend.

According to Rohault, the great cause of rain is the heat of the air, which, after continuing for some time near the earth, is at length carried up on high by a wind, and there thawing the snowy villi, or flocks of the half frozen vesiculæ, reduces them into drops; which, coalescing, descend.

Others, as Dr. Clarke, &c. ascribe this descent of the clouds rather to an alteration of the atmosphere than of the vesiculæ; and suppose it to arise from a diminution of the elastic force of the air. This elasticity, which depends chiefly or wholly on the terrene exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall.

Now the little vesicles, being once upon the descent, will persist therein, notwithstanding the increase of resistance they every moment meet with. For as they all tend toward the center of the earth, the farther they fall, the more coalitions will they make; and the more coalitions, the more matter will there be under the same surface; the surface only increasing as the squares, but the solidity as the cube; and the more matter under the same surface, the less resistance there will be to the same matter. Thus, if the cold, wind, &c. act early enough to precipitate the ascending vesicles, before they are arrived at any considerable height, the coalitions being but few, the drops will be proportionably small; and thus is formed a dew. If the vapours be more copious, and rise a little higher, we have a mist or fog. A little higher still, and they produce a small rain, &c. If they neither meet with cold nor wind, they form a heavy, thick, dark sky.

Hence, many of the phenomena of the weather may be accounted for: as, Why a cold summer is always a wet one, and a warm, a dry one? Why we have commonly most rain about the equinoxes? Why a settled, thick, close sky, scarce ever rains, till it have been first clear?

As to the quantity of rain that falls, its proportion in several places at the same time, and in the same place at several times, we have store of observations, journals, &c. in the Memoirs of the French Academy, Philosophical Transactions, &c.

Preternatural RAINS, as of blood, are very frequent in our annals, and even in natural histories; yet, if enquired into, they will be found other things than rain.

Those rains, Dr. Merret observes, are nothing more than the excrements of insects, as butterflies, &c.

The same gentleman adds, that it is very evident the rains of wheat are nothing but ivy-berries swallowed by the starling, and voided again by stool. See an instance of such rain in the Philosophical Transactions.

RAINBOW, or *Bow*, *Iris*, a meteor, in form of a party-coloured semi-circle, exhibited in a rainy sky opposite to the sun, by the refraction of his rays in drops of falling rain.

There is, also, a secondary bow which is fainter, usually investing the former at some distance.

The rainbow, Sir Isaac Newton observes, never appears but where it rains in the sun-shine; and may be represented artificially, by contriving water to fall in little drops, like rain, through which the sun, shining, exhibits a bow to a spectator placed between the sun and the drops; especially, if a black cloth be disposed beyond the drops.

Anton. de Dominis first accounted for the rainbow in 1611, by refraction and reflexion of the sun-beams in spherical drops of water; which he confirmed by experiments made with glass globes, &c. full of water; wherein he was followed by Des Cartes, who improved upon his account. But the Newtonian doctrine of colours supplies and corrects their explications.

Theory

Theory of the RAINBOW.—Let B N F G (plate CVIII. fig. 1.) be a spherical drop of falling rain, and A N a ray of the sun falling upon it in the point N, which ray suppose refracted to F, from thence reflected to G, and there again refracted in the direction G R to the eye of a spectator; and let I G be perpendicular to the point G: Then will the beam, by its refraction at G, be separated into its several sorts of rays, which will paint their respective colours in that part of the drop, of which that next the perpendicular I G will be red, as being least refracted, and the rest, in order, above it. Now, it is found by computation, that the greatest angle S E O (fig. 2.) or E O P (drawing O P parallel to S E) under which the most refrangible rays can come to the eye of a spectator at O, is 40 deg. 17 min. and that the greatest angle F O P, under which the least refrangible rays come to the eye at O, is 42 deg. 2 min. And so all the particles of water within the difference of those two angles E F, will exhibit, severally, the various colours of the prism, and constitute the interior bow in the cloud.

If the beam go not out of the drop at G (fig. 1.) but is reflected (a second time) to H, and is there refracted in the direction H S, making the angle S Y A with the incident ray A N, it will paint on the part H the several colours of light, but in an inverse order to the former, and more faint, by reason of the rays lost by the second reflection. It has been found, also, that the least angle S G O, or G O P (fig. 2.) under which the least refrangible rays can come to the eye at O, after two reflections and two refractions, is 50 deg. 57. min. and the least angle H O P, under which the most refrangible rays can come to the eye in this case, is 54 deg. 7 min. Whence all the colours of the exterior bow will be formed in the drops from G to H, which is the breadth of this bow, viz. 3 deg. 10 min. whereas the breadth of the other, viz. E F, is but 1 deg. 45 min. and the distance between the bows, viz. F G, is 8 deg. 55 min. And such would be the measure of the bows, were the sun but a point; but since his body subtends an angle of half a deg. it is evident, by so much each bow will be increased, and their distance diminished.

To apprehend rightly the different affections of this remarkable phenomenon, we must attend to the following particulars: First, That though each bow be occasioned by the refracted and reflected light of the sun falling on the drops of rain, yet neither of them is produced by any rays falling on any part of the drop indifferently, but by those only which fall on the surface of the drop B L Q G (fig. 1.) in or about the point N, as the ray A N; those which fall nearer to B, or farther towards L, being unconcerned in this production.

Secondly, The internal bow is produced by two refractions, and one reflection. The first reflection is of the incident rays extremely near A N, by which they proceed from N to one common point or focus at F, from whence they are reflected to G, and are there a second time refracted towards R, and produce the various colours of the said bow.

Thirdly, There is a necessity that several rays should be refracted together to the point F (fig. 3.) that being reflected together from thence to G, they may there go out parallel, and so come in quantity sufficient to excite the sensation of colours in a strong and lively manner. Now those rays, and those only, which are incident on the globule about the point N, can do this, as will appear from what follows: for,

Fourthly, The point F makes the arch Q F a maximum, or the distance Q F from the axis of the drop S Q is greater than any other distance from whence any other rays nearer to the axis, as S D, S E, or farther from it, as S H, S I, are reflected; because those which are nearer after the first refraction tend to points in the axis produced more remote than that to which the ray S N tends; and, therefore, as their distance from the axis increases, so, likewise, will the distances of their points of reflection Q P, Q O, till the ray becomes S N; after which, the rays more remote from the axis, as S H, S I, are refracted towards the points X Y, which are nearer and nearer to the axis: And this occasions the points of the reflection on the farthest side of the drop to decrease again from F towards Q.

Fifthly, Hence it will necessarily happen, that some rays above and below the ray S N will fall upon the same point, as O or P on the farthest side; and, for that reason, they will be so reflected from thence, as to go out of the drop by refraction parallel to each other. Thus, let S E below, and S H above the ray S N, be refracted both to one point O; from whence they will be reflected to M and L, and will there emerge parallel, it is true, but alone; being divested of their intermediate rays S N, which, going to a different point F, will be reflected in a different direction to G, and emerge on one side, and not between those rays, as when they were incident on the drop. All which is evident from the figure.

Sixthly, As this will be the case of all the rays which are not indefinitely near to S N, it is plain, that being deprived of the intermediate rays, their density will be so far diminished, as to render them ineffectual for exciting the sensation of colours; and they are therefore called inefficacious rays, in contradistinction to those which enter the drop near S N, and which, having the same point F of reflection, are not scattered like the others, but emerge together at G, so as to constitute a beam G R of the same density with the incident beam S N, and therefore capable of exhibiting a vivid appearance of colours, and for this reason are called efficacious rays.

Phænomena of the RAINBOW.—The first is, that each is variegated with all the prismatic colours, This is a necessary consequence of the different refrangibility of the rays refracted and reflected in drops of falling rain. Let A (plate CVIII. fig. 9.) be such a drop, S N a ray entering in at N, which is refracted to F, from whence refracted to G, where, as it emerges, it is refracted into all the several sorts of rays of which it is composed, viz. G R, the least refrangible or red-making ray, G O the orange, G Y the yellow, G G the green, G B the blue, G I the indigo, and G V the violet, or most refrangible ray.

The truth of this may be easily proved by experiment, by suspending a glass globe filled with water in the sunshine, and viewing it in such a position, that the rays S N will fall upon it, and emerge to the eye at A, under the several angles from S F R to S F V; which may be easily effected by letting the globe descend from A to G, by a string going over a pulley.

Hence, the second phenomenon, viz. the circular form, is accounted for, and, also, the third, which is the breadth of the bow; for that will be equal to the angle $ARG = RGV = 1^{\circ} 45'$, where the ray as here emerges after one reflection. These particulars are represented more completely in fig. 10. where B G D is the red circumference formed by the rotation of the ray A G, that can first come to the eye at A; and C g F is the violet arch formed by the least refrangible ray g A; after which the rays are all refracted below the eye. And thus, by the intermediate rays and colours, the whole interior bow is produced.

The fourth phenomenon is the appearance of two bows. This follows from hence, that after an efficacious ray of light S N, entering a drop of rain, has been twice reflected on the farthest side at F and H, it will emerge refracted into all its simple or constituent rays at G, upon the upper side of the drop, so as to make with the incident ray the angle G Y N, or S Y A, $= 54^{\circ} 10'$, if that ray be the violet sort, or most refrangible; but if it be of the red or least refrangible sort, then the said angle is but $50^{\circ} 58' = S Y A$.

Therefore, all those drops which are so situated around the eye, that their most refrangible rays shall fall upon it, must with those rays make an angle with the line A P passing through the eye parallel to the sun's rays, viz. the angle G A P, equal to the angle S Y A, or $GAP = 54^{\circ} 10'$. These rays, therefore, will every-where exhibit a violet colour in the arch P G L. For the same reason, those drops whose least refrangible rays fall upon the eye at A, make the angle $gAP = 50^{\circ} 58'$; and so the ray A g, revolving about the axis A Q, will describe the circular arch M g K, which will exhibit the deepest red; and all the drops between G and g will paint the several other coloured peripheries, all which together will complete the exterior bow.

The fifth phenomenon is the greater breadth of the exterior bow. Thus, if from $54^{\circ} 10'$ we subduct $50^{\circ} 58'$, we shall have $3^{\circ} 12' = Gg =$ the width of the outer bow; which, therefore, is almost twice as wide as the interior bow.

The sixth phenomenon is the distance between the two bows, which is thus determined: from the angle which the least refrangible ray in the upper bow makes with the axis AP, viz. $50^{\circ} 58'$, subtract the angle $42^{\circ} 02'$, which the most refrangible rays make therewith in the lower bow, and the remainder $8^{\circ} 56' = gAF$ is the arch of distance between the bows.

The seventh phenomenon is the inverse order of the colours in the two bows. This follows from the contrary parts of the drop on which the ray is incident, and from whence it emerges and is refracted. Thus, because the rays SN enter the upper part of the drop, and emerge from the lower, it is evident the rays refracted in this case (viz. in the interior bow) will have a situation quite the reverse of those which enter on the lower part of the drop, and are refracted from the upper, as in the exterior bow, whose colours are violet, indigo, blue, green, yellow, orange, and red; whilst those of the other are red, orange, yellow, green, blue, indigo, and violet; counting from the upper parts downwards in both.

The eighth phenomenon is the faintness of the exterior bow, in comparison of the interior one. This is the consequence of the rays being twice reflected within the drops, which form the outer bow. They who make the experiment in a dark chamber, may wonder when they observe how large a part of the beam (that enters the globule at N) goes out at F, that there should be enough in the remaining part FG to exhibit the colours so strong and vivid in the first bow as they appear; but then considering how much of this residual ray is refracted at G, it is rather a wonder how the very small part reflected to H, should there, when refracted, be in quantity sufficient to excite any distinct ideas of colours at all.

The ninth phenomenon is, that sometimes more than two bows appear; as in a very black cloud we have observed four, and a faint appearance of a fifth: But this happens rarely. Now, these spurious bows, as we may call them, cannot be formed in the manner as the two principal bows are, that is, by refraction after a third, fourth, fifth, &c. refraction; for the beam is by much too weak to exhibit colours by refraction, even after the third reflection only, much less would it after a fourth or fifth. Besides, though after a third and fourth reflection of the rays they should be supposed capable of shewing their colours, yet the bows made thereby would not appear at the same time with the other two, nor in the same part of the heavens, but in the rain between us and the sun, and must be viewed by the spectator's face turned towards the sun, and not from it, as in the other case.

The tenth phenomenon is the appearance of the bows in that part of the heavens opposite to the sun. This necessarily happens from the incident and emergent ray being both on one side of the drop; for it is evident, that in order to see the colours, we must look to that part against which the sun shines.

The eleventh phenomenon is, that they never appear but when and where it rains. This is because rain affords a sufficient plenty of drops, or aqueous spherules, proper to reflect and refract the light fit for this purpose, which cannot be done without a requisite size, figure, and disposition of the particles, which the vapour of the cloud does not admit, and therefore clouds alone exhibit no such appearance.

The twelfth phenomenon is the dimension of the bows. This is determined easily, for continuing the axis AP to Q the center of the bows, we have the semi-diameter of each bow in the angle QAg, or QAG; the double of which gives the angles which the whole diameters of the bows subtend, and are therefore the measure of their magnitude.

The thirteenth phenomenon is, the altitude of the bow above the horizon, or surface of the earth. This is equal to the angle GAT, which may be taken by a quadrant, or it may be known for any time by having given

the sun's altitude, which is equal to the angle TAQ; which therefore subducted from the constant angles QAF, or QAY, will always leave the angle of the apparent height of the bow.

Lunar RAINBOW.—The moon sometimes also exhibits the phenomenon of an iris, by the refraction of her rays in drops of rain in the night-time.

Aristotle says, he was the first that ever observed it, and adds that it is never visible, but at the time of full moon.

The lunar iris has all the colours of the solar, only fainter. See Phil. Transf. N^o. 331.

Marine RAINBOW, the sea-bow, is a phenomenon sometimes observed in a much agitated sea, when the wind, sweeping part of the tops of the waves, carries them aloft; so that the rays of the sun are refracted, &c. as in a common shower.

F. Bourzes in Phil. Transf. observes, that there are scarce above two colours distinguishable, a dark yellow on the side next the sun, and a pale green on the opposite side. But there are sometimes twenty or thirty of them seen together. They appear at noon-day, and in a position opposite to that of the common bow, the concave side being turned upwards.

There is a kind of white colourless rainbow which Mentzelius and others saw at noon-day. Mr. Marriote in his fourth *Essai de Physique* says, they are formed in mists, as the others are in showers; having observed several of them both after sun-rising and in the night.

The want of colours in these is owing to the exceeding tenuity of the vesicles of the vapour, which being only little watery pellicles bloated with air, the rays of light undergo but little refraction in passing out of air into them. Hence, the rays are reflected compounded, as they come.

Rohault mentions coloured rainbows on the grass formed in the morning dew.

RAISER, in building, a board set on edge under the fore side of a step, stair, &c.

RAISING-PIECES, or *REASON-PIECES*, in architecture, are pieces that lie under the beams, and over the posts or puncheons.

RAISING, in navigation, the heightening any distant object at sea, by approaching it, and levelling the intermediate space, the convexity of which intercepts the view. See the articles *EARTH* and *HORIZON*.

RAISING a Purchase, amongst sailors, the disposition of the machines, and component parts, in the proper order, to assist the motion of each other, and co-operate to produce the effect required.

RAISINS, grapes prepared by suffering them to remain on the vine till they are perfectly ripe, and then drying them in the sun, or by the heat of an oven. The difference between raisins dried in the sun, and those dried in ovens, is very obvious; the former are sweet and pleasant, but the latter have a latent acidity with the sweetness that renders them much less agreeable.

The common way of drying grapes for raisins, is to tie two or three bunches of them together while yet on the vine, and dip them into a hot lixivium of wood-ashes, with a little of the oil of olives in it. This disposes them to shrink and wrinkle, and after this they are left on the vine three or four days separated on sticks in an horizontal situation, and then dried in the sun at leisure, after being cut from the tree. The finest and best raisins are those called in some places *Damascus* and *Jube* raisins; which are distinguished from the others by their size and figures: these are flat and wrinkled on the surface, soft and juicy within, and near an inch long, and when fresh and growing on the bunch, are of the size and shape of a large olive.

The raisins of the sun, and jar-raisins, are all dried by the heat of the sun, and these are the sorts used in medicine. However, all the kinds have much the same virtues; they are all nutritive and balsamic: they are allowed to be attenuant, are said to be good in nephritic complaints, and are an ingredient in pectoral decoctions, in which cases, as also in all others where astringency is not required of them, they should have the stones carefully taken out.

RAITING, or **RATING**, the laying of flax, hemp, timber, &c. when green, in a pond or running water, to season, and prepare it for future uses.

RAKE of a *Ship*, the projection of the stem and stern beyond the fore-moſt and aftmoſt ends of the keel. Thus, if a plumb-line were ſuſpended over the ſtern, till it reaches as low as the keel, then would the diſtance between the after end of the keel and the plummet be the rake.

The diagonal line reaching up from the keel to the top of the ſtern, comprehending her length in different heights, is alſo termed the rake: upon this the beauty of a ſhip conſiderably depends.

RAKING *fore and aft*, in the ſea language, the act of cannonading a ſhip through either of the ends, by which the ſhot rake the whole length of her decks, and generally produce a great ſlaughter of the crew. This is the ſame operation with what is termed enfilade in the attack of defence or fortified places.

RAKING of an *horſe*, is drawing the ordure with the hand out of the fundament, when he is coſtive, and cannot dung: in doing which the hand ſhould be anointed with butter or ſallad oil.

RAKING-TABLE, or **RAKED-TABLE**, among architects, is a member hollowed in the ſquare of a pedeaſtal, &c.

RALLYING, in war, re-aſſembling or calling together troops broken and put to flight.

RAM, in zoology, the male of the ſheep kind. See the article **SHEEP**.

RAM, in aſtronomy, the ſame with aries. See the article **ARIES**.

Battering RAM, in antiquity, a military engine uſed to batter and beat down the walls of places beſieged. See **BATTERING-RAM**.

RAMADAN, a ſolemn ſeaſon of faſting among the Mahometans, kept in the ninth month of the Arabic year. This faſt conſiſts in abſtaining from meat and drink, and from lying with their wives each day, from the riſing of the ſun till the ſtars appear; and is of ſuch ſtrict obligation, that none is excuſed from it; for the ſick, and all others who cannot obſerve it in this month, are obliged to faſt another entire month inſtead of it. So ſuperſtitious are the Mahometans in the obſervance of this lent, that they dare not waſh their mouths or even ſwallow their ſpittle. The men are, indeed, allowed to bathe themſelves, on condition they do not plunge the head under water, leſt ſome drops enter by the mouth or ears, &c. but as for the women, they are ſtrictly forbid bathing, for fear of taking in water at the pudendum. However, they frequently feaſt all night. The Mahometans call this month holy, and believe, that as long as it laſts, the gates of paradise are open, and thoſe of hell ſhut.

RAMAGE, the boughs or branches of trees.

RAMIFICATION, the production of boughs or branches, or of figures reſembling branches.

RAMMER, an inſtrument uſed for driving down ſtones or piles into the ground; or for beating the earth, in order to render it more ſolid for a foundation.

RAMMER of a *Gun*, the gun-ſtick; a rod uſed in charging of a gun, to drive home the powder, as alſo the ſhot and wad, which keeps the ſhot from rolling out. The rammer of a great gun is uſed for the ſame purpoſe. It has a round piece of wood at one end, and the other is uſually rolled in a piece of ſheep-ſkin, fitted to the bore of the piece, and is uſed to clear her after ſhe has been diſcharged, which is called ſpunging the piece.

RAMPANT, in heraldry, a term applied to a lion, leopard, or other beaſt that ſtands on his hind legs, and rears up his fore feet in the poſture of climbing, ſhewing only half his face, as one eye, &c. It is different from ſaliant, in which the beaſt ſeems ſpringing forward as if making a ſally.

RAMPART, in fortification, is an elevation of earth round a place capable of reſiſting the cannon of an enemy; and formed into baſtions, curtains, &c.

A rampart ought to be ſloped on both ſides, and to be broad enough to allow room for the marching of waggons and cannon, beſide that allowed for the parapet which is raiſed on it; its thickneſs is generally about ten or twelve

fathom, and its height not above three, which is ſufficient to cover the houſes from the battery of the cannon. The rampart is encompassed with a ditch, and is ſometimes lined or fortified on the inſide, otherwiſe it has a berme.

Upon the rampart ſoldiers continually keep guard, and pieces of artillery are planted there for the defence of the place.

RAMPART, in civil architecture, is uſed for the ſpace left between the wall of a city, and the next houſes.

RAMPION, *Rapuntium*, in botany, a genus of plants, the flower of which conſiſts of one leaf, which is of an anomalous figure, hollowed like a pipe, and furrowed or channelled; divided, as it were, into many parts, in the ſhape of a tongue, defended by a vagina or covering, which inſolds the pointal: when the flowers decay, the flower-cup turns to a fruit divided into three cells, full of ſmall ſeeds, which adhere to a placenta, which is divided into three parts.

The crimſon rapuntium is greatly prized by the curious, for the beauty of its rich crimſon flowers, which exceed all the flowers I have yet ſeen, in the deepneſs of its colour: and theſe commonly, when their roots are ſtrong, produce large ſpikes of theſe flowers, which continue a long time in beauty, and make a moſt magnificent ſhew amongſt other flowers. The time of their flowering is commonly in July and Auguſt; and if the autumn prove very favourable, they will ſometimes produce good ſeeds in England. Theſe plants are natives of Virginia and Carolina, where they grow by the ſides of rivulets, and make a moſt beautiful appearance; from whence the ſeeds are often ſent into England. Theſe ſeeds commonly arrive here in the ſpring; at which time they ſhould be ſown in pots filled with light earth, and but juſt covered over; for, if the ſeeds are buried deep, they will not grow. Theſe pots ſhould be placed under a frame, to defend them from cold, until the ſeaſon is a little advanced; but they ſhould not be placed on an hot-bed, which will alſo deſtroy the ſeeds.

When the weather is warm, towards the middle of April, theſe pots ſhould be placed in the open air, in a ſituation where they may have the morning ſun till twelve o'clock, obſerving to water them conſtantly in dry weather; and, when the plants are come up, and are grown pretty ſtrong, they ſhould be tranſplanted each into a ſmall pot filled with freſh light earth, and placed in the ſame ſituation, obſerving to water them in dry weather; and, in winter, they ſhould be placed under an hot-bed-frame, where they may be ſheltered from ſevere froſts; but, in mild weather, they ſhould be as much expoſed to the open air as poſſible.

The March following theſe plants ſhould be put into larger pots filled with the ſame freſh earth, and placed, as before, to the morning ſun; obſerving to water them in dry weather, which will cauſe them to flower ſtrong the autumn following.

Theſe plants are alſo propagated by parting of their roots: the beſt ſeaſon for which is, either ſoon after they are paſt flower, or in March; obſerving to water and manage them, as hath been directed for the ſeedling plants, both in winter and ſummer. *Miller's Gard. Diſt.*

RANCID denotes a fatty ſubſtance that is become rank or muſty; or has contracted an ill ſmell by being kept cloſe.

RANDOM SHOT, in gunnery, is a ſhot made when the muzzle of a gun is raiſed above the horizontal line, and is not deſigned to ſhoot directly, or point blank.

The utmoſt random of any piece is about ten times as far as the bullet will go point blank. The bullet will go fartheſt when the piece is mounted to about 45° above the level range. See **GUNNERY**.

RANGE of the *Cable*, amongſt ſailors, a ſufficient length of it drawn upon deck before the anchor is caſt off, to let it ſink into the ground without being interrupted by the cable; accordingly the length of this range ought to be equal to the depth of the water where the anchor is to be ſunk to ride the ſhip.

RANGE, in gunnery, the path of a bullet, or the line it deſcribes from the mouth of the piece to the point where it lodges. If the piece lie in a line parallel to the horizon, it is called the right or level range: if it

be mounted to 45° , it is said to have the utmost range : all others between 00 and 45° are called the intermediate ranges.

RANGER, a sworn officer of a forest, appointed by the king's letters-patent, whose business is to walk thro' his charge, to drive back the deer out of the purlieus, &c. and to present all trespasses within his jurisdiction at the next forest-court.

RANGING, in war, disposing the troops in the order proper for engagement, or for marching.

RANGING, in building, signifies running straight, when the sides of a work do not break into angles.

RANK, the order or place allotted a person suitable to his quality or merit.

RANSOM, a sum of money paid for the redemption of a slave, or for the liberty of a prisoner of war. In our law-books ransom is also used for a sum paid for the pardon of some great offence, and to obtain the offender's liberty.

RANT, in the drama, an extravagant, unnatural, and improbable flight of passion.

RANULA, or **RANA**, in medicine, a tumour under the tongue, which like a ligature hinders a child from speaking or sucking.

The matter contained in these tumours is various, it being sometimes a tenacious and mucous lymph, sometimes a thick and purulent matter, and sometimes of a hard and stony consistence.

The safest method of cure, according to Heister, is to turn the tongue upwards, and to make a transverse incision through the tumour, in order to discharge the included matter ; after which you may deterge or destroy the remaining tunic with honey of roses sharpened with spirits of vitriol, and then the cure may be easily completed with a mixture of oil and sugar. Sometimes the tubercle breaks of itself, and then you must deterge and heal the ulcer as before.

RANUNCULUS, in botany, a genus of plants, the flower of which consists of several leaves, which are placed in a circular order, and expanded in form of a rose ; having, for the most part, a many leaved empalement or flower-cup ; out of the middle of the flower rises the pointal, which afterwards becomes a fruit, either round, cylindrical, or spiked ; to the axis of which as a placenta, adhere many seeds, for the most part naked.

There are a great variety of species of ranunculus ; but that called the Persian ranunculus being universally admired, we shall only give the method of cultivating that beautiful flower.

The beds in which the Persian ranunculus roots are planted, should be made with fresh light sandy earth, at least three feet deep ; the best soil for them may be composed in this manner, viz. take a quantity of fresh earth from a rich upland pasture, about six inches deep, together with the green sward : this should be laid in an heap to rot, for twelve months before it is mixed, observing to turn it over very often, to sweeten it, and break the clods : to this you should add a fourth part of very rotten neat's dung, and a proportionable quantity of sea or drift sand, according as the earth is lighter or stiffer ; if it be light, and inclining to a sand, there should be no sand added ; but if it be an hazel loam, one load of sand will be sufficient for eight loads of earth : but if the earth is strong and heavy, the sand should be added in a greater proportion : this should be mixed six or eight months before it is used ; and you should often turn it over, in order to unite their parts well together, before it is put into the beds.

The depth which this should be laid in the beds, must be about three feet ; this should be below the surface, in proportion to the dryness or moisture of the place where they are situated ; which, in dry ground, should be two feet eight inches below the surface, and the beds raised four inches above ; but in a moist place they should be two feet four inches below, and eight above the ground ; and, in this case, it will be very proper to lay some rubbish and stones at the bottom of each bed, to drain off the moisture ; and if, upon this, at the bottom of the beds, some very rotten neat's dung is laid two or three

inches thick, the roots will reach this in the spring, and the flowers will be the fairer. This earth I would by no means advise to be screened very fine : only, in turning it over each time, you should be careful to break the clods, and throw out all large stones, which will be sufficient ; for if it is made very fine, when the great rains in winter come on, it will cause the earth to bind into one solid lump, whereby the moisture will be detained, and the roots, not being able to extend their tender fibres, will rot.

The beds, being thus prepared, should lie a fortnight to settle, before the roots are planted, that there may be no danger of the earth settling unequally after they are planted ; which would prejudice the roots, by having hollow places in some parts of the bed, to which the water would run and lodge, and so rot the roots in such places. Then having levelled the earth, laying the surface a little rounding, you should mark out the rows by a line, at about six inches distance each way, so that roots may be planted every way in straight lines ; then you should open the earth with your fingers at each cross, where the roots are to be planted, about two inches deep ; placing the roots exactly in the middle, with their crowns upright ; then with the head of a rake, you should draw the earth upon the surface of the bed level, whereby the top of the roots will be about an inch covered with earth, which will be sufficient at first. This work should be done in dry weather, because the earth will then work better than if it were wet ; but the sooner after planting there happens to be rain, the better it will be for the roots, for if it should prove dry weather long after, and the earth of the beds be very dry, the roots will be subject to mould and decay ; therefore, in such a case, it will be proper to give a little water to the beds, if there should no rain happen in a fortnight's time, which is very rare at that season of the year ; so that they will seldom be in danger of suffering that way.

When the roots are thus planted, there will no more be required until towards the end of November ; by which time they will begin to heave the ground, and their beds appear ; when you should lay a little of the same fresh earth, of which the beds were composed, about half an inch thick all over the beds, which will greatly defend the crown of the root from frost : and when you perceive the buds to break through this second covering, if it should prove very hard frost, it will be very proper to arch the beds over with hoops, and cover them with mats, especially in the spring, when the flower buds will begin to appear ; for if they are exposed to too much frost, or blighting winds, at that season, their flowers seldom open fairly, and many times their roots are destroyed : but this happens more frequently to the Persian kinds, which are tenderer, than to those sorts which are pretty hardy ; for which reason they are commonly planted in open borders, intermixed with other flowers, though in very hard winters these are apt to suffer, where care is not taken to guard off the frost.

In the beginning of March the flower stems will begin to rise, at which time you should carefully clear the beds from weeds, and stir the earth with your fingers between the roots, being very careful not to injure them ; this will not only make the beds appear handsome, but also greatly strengthen their flowers. When the flowers are past, and the leaves are withered, you should take up the roots, and carefully clear them from the earth ; then spread them upon a mat to dry, in a shady place ; after which they may be put up in bags or boxes, in a dry room, until the October following, which is the season for planting them again.

RANULARES, or **RANINE VEINS**, in anatomy, two veins under the apex of the tongue, which arise from the internal jugular, and run on either side the linea mediana. See **TONGUE**.

RAPACIOUS ANIMALS are such as live upon prey.

RAPE, in law, the having carnal knowledge of a woman by force and against her will.

The civilians make another kind of rape, called rape of subornation or seduction ; which is seducing a maid either

either to uncleanness or marriage, and that by gentle means, provided there be a considerable disparity in the age and circumstances of the parties.

RAPE of the Forest, a trespass committed in a forest by violence.

RAPE is also a name given to a division of a county, and sometimes means the same as a hundred, and at other times signifies a division consisting of several hundreds; thus Suffex is divided into six rapes, every one of which, besides its hundreds, has a castle, a river, and forest belonging to it. The like parts in other counties are called tithings, laths, or wapentakes.

RAPE also signifies the stalks of the clusters of grapes when dried and freed from the fruit. This is used in making vinegar.

RAPE. See the article **NAVEW**.

RAPHANUS, the radish. See **RADISH**.

RAPIER formerly signified a long, old fashioned broad sword, such as those worn by the common soldiers: but it now denotes a small sword, such as contradistinguishing from a back-sword.

RAPINE, in law, taking away another's goods, &c. openly and by violence.

RAPTURE, **RAPTURA**, an extasy or transport of mind. See **EXTASY**, **ENTHUSIASM**, &c.

RAREFACTION, *rarefactio*, in physics, the act whereby a body is rendered rare; that is, brought to possess more room, or appear under a larger bulk without accession of any new matter.

Rarefaction is most properly restrained to that expansion of a mass into a larger bulk, which is effected by heat. All expansion from other causes they call dilatation.

It is by rarefaction that gunpowder has its effect, and to the same principle also we owe our æolipiles, thermometers, &c. The degree to which the air is rarifiable, exceeds all imagination; such is the rarefaction of common air from its own principle of elasticity, and without any previous condensation, that Mr. Boyle found it to dilate itself so as to take up 13679 times its former space; and when compressed, the same author found its greatest space when most rarified, to its least when most condensed, as 550000 to 1.

Such an immense rarefaction, Sir Isaac Newton shews is inconceivable on any other principle than that of a repelling force inherent in the air, whereby its particles mutually fly from one another. This repelling force, he observes, is much more considerable in air than in other bodies, as being generated from the most fixed bodies, and that with much difficulty, and scarce without fermentation; those principles being always found to fly each other with the most force, which, when in contact, cohere the most firmly. M. Mariotte established this as a principle, from experiments, that the different rarefactions or condensations of the air follow the proportion of the weights wherewith it is pressed. Hence, supposing the mercury in the level of the sea suspended to 28 inches, which is the weight of the whole atmosphere; and that 60 feet height of air are equivalent to a line or $\frac{1}{12}$ of an inch of mercury, so that the barometer at the height of 60 feet from the sea, would fall a line; it is easy finding what height of air would be equal to a second, or any other line of mercury; for, as 28 inches of mercury $\frac{1}{12}$ are to 28 inches, so is the height of 60 feet of air to a fourth term, which is the height of air corresponding to a second line of mercury. And after the same manner may the height of air corresponding to each line be found, which will make a geometrical progression, the sum whereof will be the whole height of the atmosphere, and of consequence a certain part of that sum will be the height of a mountain, at whose top the barometer shall have sunk a certain quantity. See **BAROMETER**.

Mess. Cassini and Maraldi, upon measuring the heights of several mountains, found that this progression of M. Mariotte was defective; that it always gave the height of the mountains, and consequently the rarefactions less, than they really were; and from some farther experiments M. Amontons found, that the principles will only hold in the mean rarefactions, not the extremes.

The open air, in which we breathe, says Sir Isaac Newton, is 8 or 900 times lighter than water, and by consequence 8 or 900 times rarer. And since the air is compressed by the weight of the incumbent atmosphere, and the density of the air is proportionable to the compressing force, it follows by computation, that at the height of about seven English miles from the earth, the air is four times rarer than at the surface of the earth; and at the height of 14 miles, it is 16 times rarer than at the surface of the earth; and at the height of 21, 28, or 35 miles, it is respectively 64, 256, or 1024 times rarer, or thereabouts; and at the height of 70, 140, and 210 miles, it is about 1000000, 1000000000000, or 1000000000000000000, &c.

Mr. Cotes has found, from experiments made with a thermometer, that linseed-oil is rarified in the proportion of 40 to 39 in the heat of the human body; in that of 15 to 14, in that degree of heat wherein water is made to boil; in the proportion of 15 to 13, in that degree of heat wherein melted tin begins to harden; and, finally, in the proportion of 23 to 20, in that degree wherein melted tin arrives at a perfect solidity. The same author discovered, that the rarefaction of the air in the same degree of heat is ten times greater than that of the linseed oil; and the rarefaction of the oil, about fifteen times greater than that of the spirit of wine.

RASANT, or **RAZANT**, in fortification. Rasant-flank, or line, is that part of the curtain or flank whence the shot exploded rase, or glance, along the surface of the opposite bastion.

RASH, in medicine, a eruption upon the skin, thrown out in fevers or surfeits.

RASPBERRY, a species of bramble growing naturally wild in the woods in the northern parts of England, but is cultivated in gardens for its fruit, which supplies the table at the season when they are ripe.

There are two or three varieties of this, one with a red, and the other a white fruit, and the third generally produces two crops of fruit annually; the first ripens in July, and the second in October, but those of the latter season have seldom much flavour.

The raspberry is generally propagated by suckers, though such plants are to be preferred as are raised by layers, because they will be better rooted, and not so liable to send out suckers as the other, which generally produce such quantities of suckers from their roots, as to fill the ground in a year or two; and where they are not carefully taken off, or thinned, will cause the fruit to be small, and in less quantities, especially when the plants are placed near each other, which is too often the case, for there are few persons who allow these plants sufficient room.

In preparing these plants, their fibres should be shortened; but the buds, which are placed at a short distance from the stem of the plant, must not be cut off, because those produce the new shoots the following summer. These plants should be planted about two feet asunder in the rows, and four or five feet distance row from row; for if they are planted too close, their fruit is never so fair, nor will ripen so kindly, as when they have room for the air to pass between the rows. The soil in which they thrive best, is a fresh strong loam, for in warm light ground they do not produce so great plenty of fruit, for they naturally grow in cold land, and in shade; therefore when they are planted in a warm situation and a light soil, they do not succeed.

The season for dressing them is in October, at which time all the old wood that produced fruit the preceding summer, should be cut down below the surface of the ground, and the young shoots of the same year must be shortened to about two feet in length; then the spaces between the rows should be well dug, to encourage their roots; and if you bury a very little rotten dung therein, it will make them shoot vigorously the following summer, and their fruit will be much fairer. During the summer season, they should be kept clear from weeds, which with the before-mentioned culture, is all the management they will require; but it is proper to make new plantations once in three or four years, because when the plants are suffered to remain long, they will produce few and small fruit.

RAT, in zoology, the English name of several species of the mus-kind; as the common rat, the ground-rat, and the water-rat.

The common rat is a quadruped too well known to need much description. It is of a brownish-grey colour, with a long and almost naked tail. It greatly resembles the common mouse in form, but it is at least five times as large: the tail is divided into more than an hundred and fifty annular joints.

The ground-rat is nearly of the size of the common rat, only that its tail is much shorter, as well as more hairy.

The water-rat is considerably larger than the common kind: its tail is all the way of the same thickness, and is abrupt at the end: its legs are shorter than those of the common rat, but its feet are longer, and the toes connected by membranes.

RAT-TAILS, or **ARRESTS**, in the manege, signify hard callous swellings upon the hinder legs under the hough, running along the finew.

A horse is called rat-tail, when he has no hair upon his tail.

RATAFIA, a fine spirituous liquor, prepared from the kernels, &c. of several kinds of fruit, particularly of cherries and apricots.

Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel wherein brandy has been long kept; then adding to them the kernels of cherries, with strawberries, sugar, cinnamon, white pepper, nutmegs, cloves; and to twenty pound of cherries, ten quarts of brandy. The vessel is left open ten or twelve days, and then stopped close for two months before it be tapped. Ratafia of apricots is prepared two ways, viz. either by boiling the apricots in white wine, adding to the liquor an equal quantity of brandy with sugar, cinnamon, mace, and the kernels of apricots; infusing the whole for eight or ten days; then straining the liquor, and putting it up for use: or else by infusing the apricots cut in pieces in brandy, for a day or two, passing it through a straining bag, and then putting in the usual ingredients.

RATCH, or **RASH**, in clock-work, a sort of wheel having twelve fangs, which serve to lift up the detents every hour, and make the clock strike. See the article **CLOCK**.

RATCHETS, in a watch, are the small teeth at the bottom of the fusee, or barrel, which stops it in winding up.

RATE, a standard or proportion, by which either the quantity or value of a thing is adjusted.

RATE, in the royal navy, the degree, or order, into which vessels of war are usually classed: of these there are six, besides sloops, armed ships, bomb-vessels, fire-ships, &c. The first comprehends the ships of 110 and 101 pieces of cannon: the second, those which carry 90: the third, those from 84 to 64: the fourth, those of 60 and 50: the fifth, those of 40, 36, and 32; and lastly, the sixth, those of 28, 24, and 20. All these are commanded by captains; those of the sloops, armed ships, &c. by an officer styled the master and commander.

RATE-TYTHE, when sheep or other cattle are kept in a parish for less time than a year, the owner must pay tythe for them, *pro rata*, according to the custom of the place.

RATEEN, or **RATTEN**, in commerce, a thick woollen stuff, quilled, woven on a loom with four treddles, like serges, and other stuffs, that have the whale or quilling. There are some rateens dressed and prepared like cloths; others left simply in the hair, and others where the hair or knap is frized. Rateens are chiefly manufactured in France, Holland, and Italy, and are mostly used in linings. The frize is a sort of coarse rateen, and the drugget is a rateen half linen, half woollen.

RATIFICATION, *Ratificatio*, an act approving of, and confirming something done by another in our name.

RATIFICATION is also used for an act confirming something we ourselves have done in our name.

RATIO, **REASON**, in arithmetic and geometry, is that relation of homogeneous things which determines

the quantity of one from the quantity of another, without the intervention of a third.

Two numbers, lines, or quantities, A and B, being proposed, their relation one to another may be considered under one of these two heads:

1. How much A exceeds B, or B exceeds A; and this is found by taking A from B, or B from A, and is called arithmetic reason or ratio.

2. Or how many times, as parts of a time, A contains B, or B contains A; and this is called geometric reason or ratio; (or, as Euclid defines it, it is the mutual habitude, or respect, of two magnitudes of the same kind, according to quantity; that is, as to how often the one contains, or is contained, in the other) and is found by dividing A by B, or B by A; and here note that that quantity which is referred to another quantity, is called the antecedent of the ratio; and that to which the other is referred, is called the consequent of the ratio; as, in the ratio of A to B, A is the antecedent, and B the consequent.

3. Therefore any quantity, as antecedent, divided by any quantity as a consequent, gives the ratio of that antecedent to the consequent.

Thus the ratio of A to B is $\frac{A}{B}$, but the ratio of B to A is $\frac{B}{A}$; and, in numbers, the ratio of 12 to 4 is $\frac{12}{4} = 3$,

or triple; but the ratio of 4 to 12 is $\frac{4}{12} = \frac{1}{3}$, or subtriple.

4. And here note, that the quantities, thus compared, must be of the same kind; that is, such, which, by multiplication, may be made to exceed one the other, or as these quantities are said to have a ratio between them, which, being multiplied, may be made to exceed one another. Thus a line, how short soever, may be multiplied, that is, produced so long as to exceed in length any given right line, and consequently these may be compared together, and the ratio expressed; but as a line can never, by any multiplication whatever, be made to have breadth, that is, to be made equal to a superficies, how small soever; these can therefore never be compared together, and consequently have no ratio or respect one to another, according to quantity; that is, as to how often the one contains, or is contained in the other. See **PROPORTION**.

RATIOCINATION, *Ratiocinatio*, the act of reasoning. See the article **REASONING**.

RATION, or **RATIAN**, in the army, a portion of ammunition bread, drink, and forage, distributed to each soldier in the army, for his daily subsistence, &c. The horse have rations of hay and oats when they cannot go out to forage. The rations of bread are regulated by weight. The ordinary ration of a foot soldier is a pound and a half of bread per day. The officers have several rations, according to their quality, and the number of attendants that they are obliged to keep. When the ration is augmented on occasions of rejoicing, it is called a double ration. The ship's crews have also their rations or allowances of biscuit, pulse, and water, proportioned according to their stock.

RATIONAL, **REASONABLE**. See **REASON**.

RATIONAL is also applied to integral, fractional, and mixed numbers: thus we say rational fraction, rational integer, and rational mixed number, for the explanation and doctrine of which, see **NUMBER** and **FRACTION**.

RATIONAL is applied to the true horizon, in opposition to the sensible or apparent one. See **HORIZON**.

RATIONAL is also applied to quantity, ratio, &c. See **QUANTITY**, **RATIO**, &c.

RATIONALE, a solution, or account of the principles of some opinion, action, hypothesis, phenomenon, or the like.

RATIONIS Os, in anatomy, a term sometimes used for the os frontis. See the article **FRONTIS Os**.

RATTLE-SNAKE, in natural history, a very dreadful species of serpents, whose bite is fatal, if not timely remedied, and which is distinguished from all other serpents by the rattle in its tail. This is composed of several scaly substances, and is said to increase by the creature's age, every year adding one scale to it. It moves

moves over the rocks and mountains with prodigious swiftness; but is less nimble on even ground, than many other snakes.

It grows to four or five feet long, and sometimes, tho' rarely, to more: one, of more than four feet long, having been dissected, and accurately described by Dr. Tyson, the account that gentleman gives of it may not be unacceptable to the reader: The body where largest, which was near the middle, measured six inches and an half round; its neck only three inches. Its head was flat, as that of the viper; and, as the jaws are very broad and protuberant, and the nose sharp, it somewhat resembles the head of an arrow. At the end of the nose are placed the nostrils; and between these and the eyes there are two other holes, which may be mistaken for ears; but they only go into a hollow of the bones of the skull, without any perforation into the brain. The viper has nothing of these holes. The eyes are round, and wholly resemble those of the viper. The whole body of the creature also greatly resembles the viper, but for the singularity of the rattle; and over the eyes there are two large scales looking like eye-brows.

The scales which cover the head are very small; thence they become gradually larger, as they reach towards the middle of the body, and from the middle to the tail they grow less and less again; and all, in shape, much resemble the broad and flat seeds of the common garden parsnip. There is some variety in the colours of this creature, whether according to the difference of age or sex, or from lesser accidents. The most usual colours are these: the scales are of a dusky greenish, like the feathers of the back of the green-finch, and are variegated with small black spots in great numbers; there are also four large ones of the same colour.

The back is of a mixed colour, of a dead yellowish brown, variegated with blotches of black and yellow, and with a number of small dots of the same colours; the larger blotches being laid in great regularity, and making a very beautiful tessellated figure. The scales become darker, as they approach the tail, where they are almost black; and those on the ridge of the back, all along, are raised into a sort of sharp prominence in their middle, like the scales of a crocodile: those on the sides are plain and flat. The belly is all along covered with oblong parallelogram scales laid transversely; these are very bright and glossy, and yellow, spotted with black.

The head is small, in proportion to the body, but the mouth is capable of opening to a prodigious width. The tongue is wholly like that of the viper, composed of two oblong portions, joined towards the bases, but separate as they approach the end. The teeth are of two kinds, the smaller ones designed for its eating with, the larger and longer for biting and poisoning what it seizes. These are only placed in the upper jaw; but all the teeth of the mouth are of the canine kind, as the creature, never chewing its prey, has no use for dentes molares, or grinders.

The poisonous teeth are situated on the outside of the jaw, in the anterior part of the mouth, not fixed in the sockets of the jaws, as the others, but fixed to two bones. These, in their natural state, are not visible, even when the creature's mouth is opened, unless it be with an intent to wound; for they lie back under a membranaceous covering, and the creature has a power of erecting and wounding with them at pleasure, as the lion and cat kind can retract or thrust out their claws. The teeth are crooked, and have a hollow at their bottom; and, at the point, a very plain and evident slit, looking like the nib of a writing-pen. The teeth are hollow all the way, from this slit to their bottom; and, on pressing the gums in a dead rattle-snake, the poisonous juice may be seen to ascend, by degrees, up the teeth, and, at length, to be discharged out of the slit at the point. This makes it very plain in what manner the poison is conveyed into the flesh, when the creature bites.

The rattle is affixed to the last vertebra of the tail, and is composed of a series of small bones; that next the tail is usually of a bluish grey colour, the rest of a pale brown. These bones are hollow, very thin, hard and dry, and of a brittle texture, and very sonorous. They

are all of the same figure, representing, in some degree, the os sacrum in the human skeleton, and all are nearly of the same size. The last of these is seen to have a rigid extremity, in manner of a tail; and all the others have the same, though it is not distinguishable in them, as, in the joining, it runs under two others, and, by means of this structure, they are all moveable with the smallest force, and the sound is the more vigorous, as each of these tails strikes on two of the hollow joints, when put into motion. The age of the creature is known by the number of joints of this rattle, which are found to be from one to twenty, or more. The use of this seems not to be to the creature itself, but to other animals, that they may be alarmed at the approach of so terrible an enemy, and get out of its way in time. Piso and some others affirm, that this rattle, put up a man's fundament, is as fatal a thing as the creature's bite. The power of doing mischief, which nature has allotted to this animal, seems not only by its bite; but, according to the joint accounts of almost all authors, it appears to have a power of destroying, even by a look.

The charming or fascination of the rattle-snake, as this is usually called, has exercised the wits of many naturalists in vain, and many have disbelieved the fact. Sir Hans Sloane mitigates the matter, by supposing the creature first to seize or bite its prey, which it then suffers to escape, as far as the poison will let it, watching its death, that it may devour it without trouble: and that it is in this poisoned state that people have seen the squirrels, &c. dancing about before the rattle-snake, and dying convulsed; all which they have attributed to the power of charming in the eye of the snake, not conceiving that it was the effect of the creature's having before bit them. This, though a very plausible account, yet, however, wants experience to confirm it, and the general testimony of people, who have seen the facts, makes against it.

The same author gives us, however, from colonel Beverly, the whole process of the charm. The colonel acquaints us, that some company he was with once saw a hare, about half grown, sitting quietly in an orchard, and, striking at her, she only removed a few yards: when wondering at the cause, they saw a rattle-snake, at about ten feet distance, eyeing the hare as his destined prey.

The poor creature was, by this time, in agonies and convulsions, often getting up on her legs, as if intending to run away, but always immediately falling down again; and, growing worse and worse, soon lost the use of its hinder legs, and, panting vehemently, fell on its side. In about half an hour more, the hare seemed to have done with all struggles, and to be dead; on which the snake uncoiled itself, and moved gently towards it, but, the poor hare starting again, he stopped; but, when all was again quiet, he moved up to it, and, raising his head, looked all over his prey, his colours looking at that instant more beautiful than before, and his eyes sparkling. The hinder part of the hare had been towards the snake all this time, and it had perished without much looking at its enemy. The snake wetted the body all over with slaver; and then, with great difficulty, taking first the head into his mouth, swallowed that, and afterwards the whole body, sucking it gently down, but not getting in the shoulders without much difficulty.

It is certain upon the whole, that there is much in this account to favour Sir Hans Sloane's opinion of the hare's having been bitten, though that was not seen, since the convulsions, and loss of the use of the hinder legs, seem a very natural effect of poison; but we are assured by persons who have been eye-witnesses to the fact, that a bird, hopping about in all this agony and terror, has, on the frightening the rattle-snake away, flown off without any difficulty: so that the whole seems not yet understood.

RATTLE-SNAKE-ROOT, in botany, a plant with oblong, somewhat oval, pointed leaves; upright unbranched stalks; white flowers; and a variously bent and divaricated jointed root, about the thickness of the little finger, with a membranous margin running its whole length on each side, externally of a yellowish or pale brownish colour, internally white. It is a native of Virginia, Pennsylvania,

Pensylvania, and Maryland, and cultivated in some of our gardens.

Dr. Tennent gives his rattle-snake-root, or Virginian polygala, in the dose of thirty-five grains in substance, or in three or four ounces of a strong infusion, or in a yet stronger, in a proportionably smaller dose. The effects of this root being found very great, it was supposed that its place might possibly be supplied by this species of our own growth. It is very certain, that the place of growth may, in some plants, make a very great alteration in their virtues; and that the different species of the same genus may, in other instances, produce different effects in the human body, some species of plants agreeing in their external forms and generical characters, while they differ in their virtues and qualities.

There appeared on trial a considerable difference to the taste between the American and the European polygala roots; that of Virginia being very aromatic, acrid, and bitter, and the European only slightly acrid, with a very feeble bitterness. Another thing that gave great suspicion as to the parallel virtues of the roots of these two species was, that Gesner was found, in his account of the virtues of the European polygala, to call it a brisk cathartic; a quality which might render its use very improper in many of the diseases in which Mr. Lemery and Jussieu found the Virginian kind to prove a serviceable medicine. This last was found always very speedily to allay fevers of the pleuritic kind, without increasing in any great degree the discharges by stool.

The roots of the European polygala, being very small and slender, gave also some trouble as to the procuring them in sufficient quantity; and in hopes it might become a general medicine, it was determined to try the effects of the whole plant, root, leaf, and branch, in the disease in which the Virginian kind had been given with the greatest success, that is, in pleuritis; and this was accordingly fairly tried.

The principal instances of their trials were two; the first to a woman of twenty-two years old, who had a violent fever, with a fizy blood, and pain in the side. She was twice bled, and had immediate, but not lasting relief from it, and was ordered the common ptisans given on these occasions. The malady increased, and the expectoration was but small, and that of a thick yellow matter: a third bleeding finally was judged necessary, but was of no more service than the others; and after this she had the same ptisan continued, but with the addition of a large quantity of the common European polygala, stalk, root, and leaf. This took place in two or three hours, the expectoration became vastly plentiful, and the matter thin and white, from being thick and yellow. The woman, in fine, was cured, and the medicine was not observed to occasion any nausea, nor did it prove, as supposed, a violent purge.

The second instance was in a man of a stout robust habit, and of twenty-five years of age. He was violently attacked with a pleurisy; he was bled seven times, and was brought into one of the hospitals delirious, and seemingly very near death: he was there bled in the foot, which restored his senses; and he took a large quantity of the decoction of the polygala, which caused him to expectorate in great abundance. The matter was first blackish, then reddish, and finally white, and the patient was perfectly cured. *Mem. Acad. Scienc. Par.* 1739.

These are such remarkable instances of the good effect of an herb to be had every-where in our own country, that they seemed very worthy to be recorded. The plant grows with us on dry grounds and heaths, and is about four inches long, not erect, but trailing upon the ground: the leaves are long and narrow, of a pale green, and the flowers are large and look beautiful: they stand in spikes, and are usually blue; but very often white, and sometimes red. The herb should be pulled up root and all for drying.

RATTLINGS, in the sea language, pieces of small cord tied horizontally from shroud to shroud to form the steps, like those of a ladder, by which the sailors climb to the mast-head, to perform the necessary business aloft. All the shrouds of a ship are rattled, except those of the

top-gallant-masts; and in Dutch vessels they are also furnished with rattlings.

RAVELIN, in fortification, was anciently a flat bastion, placed in the middle of a curtain; but now a detached work composed only of two faces, which make a salient angle, without any flanks, and raised before the curtain on the counterscarp of the place. A ravelin is a triangular work, resembling the point of a bastion, with the flanks cut off.

RAVEN, in ornithology, a species of the corvus. See CORVUS.

RAVISHMENT, in law, denotes an unlawful seducing either of a woman, or an heir that is in ward: sometimes it is also used in the same sense as a rape.

RAY, in optics, a beam of light, emitted from a radiant, or luminous body. See LIGHT.

Rays are defined by Sir Isaac Newton, to be the least parts of light, whether successive in the same line, or cotemporary in several lines. For that light consists of parts of both kinds is evident, since one may stop what comes this moment in any point, and let pass that which comes presently after: now the least light or part of light, which may be thus stopped, he calls a ray of light.

A ray or right line, drawn from the point of concourse of the two optical axes, through the middle of the right line, which passes by the centers of the two pupils of the eyes, is by some called a common ray.

RAYONANT, or CROSS RAYONANT, in heraldry, one which has rays of glory behind it, darting out from the center to all the quarters of the escutcheon.

RE, in grammar, an inseparable particle added to the beginning of words, to double, or otherwise modify, their meaning; as in *re-action*, *re-move*, *re-export*, &c.

RE-ACTION, in physiology, the resistance made by all bodies to the action or impulse of others, that endeavour to change its state, whether of motion or rest.

REACH, any portion of a river which runs upon a straight line, comprehending the nearest distance between two points.

READINGS, or various READINGS, *Variae Lectiones*, in criticism, are the different manner of reading the texts of authors in antient manuscripts, where a diversity has arisen from the corruption of time, or the ignorance of copyists. A great part of the business of critics lies in settling the readings, by confronting the various readings of the several manuscripts, and considering the agreement of the words and sense.

REAL, *reale*, is applied to a being that actually exists, in which sense it coincides with actual.

REAL, in law, is opposed to personal.

Thus real action is that whereby the plaintiff lays title to land, &c.

REALGAR, *Risigallum*, in the materia medica, a name whereby the sandarach has been a long time known in the shops. It has been also attributed to the factitious red arsenic. See the articles SANDARACH and ARSENIC.

REALISTS, *Realistæ*, a sect of school philosophers, formed in opposition to the Nominalists.

Under the Realists are included the Scotists, Thomists, and all excepting the followers of Ocham. Their distinguishing tenet is, that universals are realities, and have an actual existence out of an idea, or imagination; or, as they express it in the schools, a *parte rei*; whereas the Nominalists contend that they exist only in the mind, and are only ideas, or manners of conceiving things.

REALM, *Regnum*, a country which gives its head, or governor, the denomination of a king.

REAR, a term frequently used in composition, to denote something behind, or backwards, in respect of another, in opposition to van; thus, in a military sense, it is used for the hind part of an army, in opposition to the front.

REAR-DIVISION of a Fleet. A squadron of ships of war is always classed in three divisions, commanded by three superior officers, and are termed, the center, the van, and rear division. The center is governed by the commander in chief, the van which advances first by the second in command, and the rear, or last division, by the next officer in rank. See CENTER, DIVISION, SQUADRON.

REASON,

REASON, *Ratio*, a faculty, or power, of the mind, whereby it distinguishes good from evil, truth from falsehood; whereby man is distinguished from beasts; and wherein it is evident he greatly surpasses them: or reason is that principle whereby, comparing several ideas together, we draw consequences from the relations they are found to have.

Some define reason to be the comprehension of many principles which the mind successively can conceive, and from which conclusions may be drawn. And others conceive reason as no other than the understanding itself considered as it discourses.

Reason, Mr. Locke observes, contains two distinct faculties of the mind, viz. sagacity, whereby it finds intermediate ideas; and illation, whereby it so orders and disposes of them, as to discover what connection there is in each link of the chain, whereby the extremes are held together; and thereby, as it were, draws into view the truth sought for. Illation, or inference, consists in nothing but the perception of the connection there is between the ideas in each step of the deduction, whereby the mind comes to see either the agreement or disagreement of any two ideas, as in demonstration, in which it arrives at knowledge; or their probable connection, on which it gives or with-holds its assent, as in opinion.

Sense and intuition reach but a little way; the greatest part of our knowledge depends upon deductions and intermediate ideas. In those cases where we must take propositions for true, without being certain that they are so, we would need to find out, examine, and compare the grounds of their probability. In both cases the faculty which finds out the means, and rightly applies them to discover certainty in the one, and probability in the other, is that which we call reason. In reason, therefore, we may consider four degrees. First, the discovering and finding out of proofs.

Secondly, the regular and methodical disposition of them, and laying them in such order, as that their connection may be plainly perceived.

Thirdly, the perceiving of their connection. And, Fourthly, the making a right conclusion.

Concerning reason, Mr. Locke thinks that syllogism, as was generally thought, is not the proper instrument of it, nor the usefulest way of exercising this faculty.

Reason, though of very large extent, fails us in several instances; as first, where our ideas fail; secondly, it is often at a loss, because of the obscurity, confusion, or imperfection of the ideas it is employed about: thus, having no perfect idea of the least extension of matter, nor of infinity, we are at a loss about the divisibility of matter. Thirdly, our reason is often at a stand, because it perceives not those ideas which would serve to shew the certain or probable agreement or disagreement of any two other ideas. Fourthly, our reason is very often engaged in absurdities and difficulties, by proceeding upon false principles, which being followed, lead men into contradictions to themselves, and inconsistency in their own thoughts. Fifthly, dubious words, and uncertain signs, often puzzle men's reason, and bring them to a nonplus. Though the deducing one proposition from another be a great part of reason, and that which it is usually employed about, yet the principal act of ratiocination is the finding the agreement or disagreement of two ideas one with another by the intervention of a third; as a man by a yard finds two houses to be of the same length, which could not be brought together to measure their equality by juxtaposition. Words have their consequences as the signs of such ideas; and things agree or disagree with what they really are, but we observe it only by our ideas. Hence we may be able to form an idea of that ordinary distinction of things into those that are according to, those that are above, and those contrary to, reason. Those according to reason, are such propositions whose truth we can discover by examining and tracing those ideas we have from sensation and reflection; and by a natural deduction find to be true or probable. Above reason are such propositions whose truth we, or probability cannot, by reason derive from these principles. Contrary to reason are such propo-

sitions as are inconsistent with, or irreconcilable to, our clear and distinct ideas. Thus the existence of one God is according to reason: the existence of more than one God, contrary to reason; and the resurrection of the body after death, above reason. Above reason may be also taken in a double sense, viz. above probability, or above certainty.

Reason, as contradistinguished to faith, Mr. Locke takes to be the discovery of the certainty or probability of such propositions or truths, as the mind arrives at, by deductions made from such ideas, which it has got by the use of its natural faculties, viz. by sensation or reflection; whereas faith, on the other hand, is the assent to any proposition upon the credit of the proposer, as coming immediately from God, which we call revelation.

This use of the word reason our author takes to be very improper; faith, as has been already observed, being nothing else but a firm assent of the mind, which if regulated, as is our duty, cannot be afforded to any thing but upon good reason, and so cannot be opposite to it.

REASON is also taken in different other significations; sometimes it denotes true and clear principles; sometimes it is taken for clear and fair deductions from these principles; and sometimes for the cause, particularly the final cause.

REASONING, **RATIOCINATION**, the exercise of that faculty of the mind called reason; or it is an act or operation of the mind, deducing some unknown proposition from other previous ones that are evident and known.

It often happens in the comparing ideas together, that their agreement or disagreement cannot be discerned at first view, especially if they are of such a nature as not to admit of an exact application to one another: here then, as has been already observed under REASON, it becomes necessary to look out after some third idea that will admit of such an application as the present case requires. Hence it appears that every act of reasoning necessarily includes three distinct judgments; two wherein the ideas whose relation we want to discover, are severally compared with the middle idea; and a third wherein they are themselves connected, or disjoined, according to the result of that comparison. Now, as our judgments when put into words are called propositions, so the expressions of our reasonings are termed syllogisms. And hence it follows that as every act of reasoning implies three several judgments, so every syllogism must include three distinct propositions. See SYLLOGISM.

In order therefore to infer a conclusion by a single act of reasoning, the premises must be intuitive propositions; where they are not, previous syllogism are required, in which case reasoning becomes a complicated act taken in a variety of successive steps. This frequently happens in tracing the more remote relations of our ideas, where many middle terms being called in, the conclusion cannot be made out, but in consequence of a series of syllogisms following one another in train. Hence we may clearly perceive that reasoning, in the highest exercise of that faculty, is no more than an orderly combination of simple acts of reasoning. See the article DEMONSTRATION.

Thus we see that reasoning, beginning with first principles, rises gradually from one judgment to another, and connects them in such a manner that every stage of the progression brings intuitive certainty along with it.

All the aims of human reasoning may in the general be reduced to these two. 1. To rank things under those universal ideas to which they truly belong; and, 2. To ascribe to them their several attributes and properties in consequence of that distribution.

This first aim of reason then is to determine the genera and species of things; and the second end regards the sciences and the affairs of common life. See GENUS, SPECIES, &c.

As in tracing the most distant relation of things we must always have recourse to intervening ideas, and are more or less successful in our researches, according to our acquaintance with those ideas, and ability of applying them, it is evident that to make a good reasoner two

things are principally required; first, an extensive knowledge of those intermediate ideas, by means of which things may be compared one with another; secondly, the skill and talent of applying them happily in all particular instances that come under consideration.

There is another species of reasoning with two propositions, which seems to be complete in itself, and where we admit the conclusion without supposing any tacit or suppressed judgment in the mind from which it follows syllogistically. This happens between propositions where the connection is such that the admission of the one necessarily, and at the first sight, implies the admission also of the other: for if it falls out that the proposition on which the other depends is self evident, we content ourselves with barely affirming it, and infer that other by a direct conclusion: thus, by admitting an universal proposition, we are forced also to admit of all the particular propositions comprehended under it; this being the very condition that constitutes a proposition universal. If then that universal proposition chances to be self evident, the particular ones follow of course, without any farther train of reasoning.

Another species of reasoning is that called by logicians induction; in order to the right understanding of which, it will be necessary to observe, that our general ideas are for the most part capable of various subdivisions: thus the idea of the lowest species may be subdivided into its several individuals; the idea of any genus into the different species it comprehends; and so of the rest. If then we suppose this distribution to be duly made, so as to take in the whole extent of the idea to which it belongs, then it is plain that all the subdivisions or parts of any idea taken together constitute that whole idea: thus the several individuals of any species taken together constitute the whole species, and all the various species comprehended under any genus make up the whole genus; this being allowed, it is apparent that whatever may be affirmed of all the several subdivisions and classes of any idea, ought to be affirmed of the whole general idea to which these subdivisions belong. What may be affirmed of all the individuals of any species, may be affirmed of the whole species; and what may be affirmed of all the species of any genus, may also be affirmed of the whole genus. This way of reasoning, where we infer universally concerning any idea, what we had before affirmed or denied separately of all its several subdivisions and parts, is called reasoning by induction: thus, if we suppose the whole tribe of animals subdivided into men, beasts, birds, insects and fishes, and then reason concerning them in this manner; all men have a power of beginning motion, all beasts, birds, and insects have a power of beginning motion, all fishes have a power of beginning motion; therefore all animals have a power of beginning motion.

RE-ATTACHMENT, in law, is a second attachment of a person, who was formerly attached and dismissed the court without day, on account of the not coming of the justices, or other such casualty: without which, a cause discontinued cannot be revived, but the defendant must plead *de novo*.

RE-BAPTISANTS, the same with Anabaptists. See **ANABAPTISTS**.

REBATE, or **REBATEMENT**, in commerce, a term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer, instead of taking time, advances ready money.

Rebate, which among us is usually called prompt-payment, is estimated by months, and is only allowed for certain merchandize, which, according to the custom of Amsterdam, are

German wools,	} which are sold at	{ 15 21 18 33 18	} months rebate.
Spanish wools,			
Ashes and pot-ashes,			
Italian silks,			
Sugars of Brazil,			

That is, those commodities are sold for ready money, only deducting or rebating the interest of the money, which need not have been paid till the end of 15, 21, &c. months. This interest is usually regulated on the foot of 8 per cent. *per annum*.

REBELLION, a traitorous taking up of arms against the king by his own natural subjects, or those formerly subdued.

REBELLIOUS ASSEMBLY, in law, an assembling together of twelve or more persons, with an intent of unlawfully making use of their own authority, to change or alter any laws of this kingdom, or to destroy the inclosures of any ground, or the banks of any fish-pond, pool, or conduit, to the intent that it may lie waste and void; or to destroy the deer in any park, fish in fish-ponds, coney in any warren; or any house, barn, mills, or bays; or to burn sacks of corn, abate rents, or prices of victuals, &c. See the article **RIOT**.

REBUS, an ænigmatical representation of some name, &c. by using figures or pictures instead of words, or parts of words.

REBUTTER, in law, the defendant's answer to the plaintiff's surrejoinder, in a cause depending in the court of Chancery, &c. also when a person warrants lands, &c.

RECAPITULATION, in oratory, &c. a part of the peroration.

Recapitulation is a summary, or concise and transient enumeration of the principal things insisted on in the preceding discourse, whereby the force of the whole is collected into one view.

RECEIPT, or **RECEIT**, in commerce, an acquittance, or discharge, in writing, intimating that the party has received a certain sum of money, either in full for the whole debt, or in part, or on account.

RECEIPT, in book-keeping, is an account of all the money and goods received. See the article **BOOK-KEEPING**.

RECEIVER, in chemistry, a vessel of earth, glass, &c. for receiving any distilled liquor.

RECEIVER, in pneumatics, a glass-vessel for containing the thing on which an experiment in the air-pump is to be made. See **AIR-PUMP**.

RECEIVER, **RECEPTOR**, or **RECEPTATOR**, in law, is commonly understood in a bad sense, and used for such as knowingly receive stolen goods from thieves, and conceal them. This crime is felony, and the punishment is transportation for fourteen years.

RECEPTACULUM CHYLI, or **PECQUET'S RESERVATORY**, the reservoir or receptacle for the chyle, situated in the left side of the upper vertebra of the loins, under the aorta, and the vessels of the left kidney.

RECEPTACULUM SEMINUM, receptacle of the seed, a term used by botanists, for the base, or thalamus, which supports the seeds: the disc of this part is either flat, concave, convex, globular, or pyramidal; and its surface is sometimes naked, and sometimes paleaceous.

RECHABITES, a kind of religious order among the Jews, instituted by Jonadab, the son of Rechab, comprehending only his own family and posterity.

Their founder prescribed them three things: first, not to drink any wine; secondly, not to build any houses, but to dwell in tents; and thirdly, not to sow any corn, or plant vines. These rules the Rechabites observed with great strictness.

RECHARGE, a second charge or loading of fire-arms.

RECHEAT, in hunting, a lesson which the huntsmen play on the horn when the hounds have lost their game, to call them back from pursuing a counter-scent.

RECIPE, in medicine, a prescription or remedy, to be taken by a patient; so called because always beginning with the word *Recipe*, that is, *Take*; which is generally denoted by the abbreviation **R**.

RECIPIANGLE, or **RECIPIENT-ANGLE**, a mathematical instrument, serving to measure re-entering and salient angles, especially in fortification.

RECIPROCAL, in general, something that is mutual, or which is returned equally on both sides, or that affects both parties alike.

There are reciprocal duties between the prince and his subjects, between the husband and wife, &c. also in a physical sense, the action between the agent and patient is reciprocal: that is, the patient re-acts as much upon the agent, as this acts upon it. See **RE-ACTION**.

RECIPROCAL TERMS, among logicians, are those which have the same signification; and consequently are convertible, or may be used for each other.

RECIPROCAL.

RECIPROCAL VERSES, in grammar, are those which express an action that is reflected upon the agent or agents, as,

Ces quatre hommes s'entrebattoient.

These four men fought together.

Reciprocal verses, in poetry, are such as run the same both forwards and backwards.

RECIPROCAL FIGURES, in geometry, those which have the antecedents and consequents of the same ratio, in both figures.

RECIPROCAL PROPORTION, in arithmetic, is when, in four numbers, the fourth is less than the second, by so much as the third is greater than the first; and *vice versa*. See PROPORTION.

RECITATIVO, or RECITATIVE, in music, a kind of fingering, that differs but little from ordinary pronunciation, such as that in which the several parts of the Liturgy are rehearsed in cathedrals; or that wherein the actors commonly deliver themselves on the theatre at the opera, when they are to express some action or passion, to relate some event, or reveal some design.

RECKONING, in navigation, is the estimation of a ship's course at sea, as measured by the log-line and glass.

See DEAD RECKONING, GLASS, JOURNAL, LOG, and NAVIGATION.

The place of the ship is discovered in the reckoning by taking the several differences of latitude and departure from the different courses the ship has run, and adding them together, if she has only run in one quadrant of the horizon, to obtain the total difference of latitude and departure made for a certain period, as 24 hours, and consequently the latitude and longitude into which the ship has arrived.

The journal in which this reckoning is formally stated, together with all the material events which happen in the course of a voyage, is variously kept, according to the fancy or caprice of the navigator. In the royal navy, indeed, there is a regular uniform method which all the officers observe; which, however, is not so accurate as might perhaps be expected.

The following method seems better calculated for this purpose. Let every page of the journal contain two days works, and a space be left at the bottom of both pages for the azimuths, amplitudes, bearings, distances, and variations, as follows:

Daily register kept aboard the Minerva in the year 1700.			
1^h November 19. At 4 P. M. Lizard bore N. W. four leagues. Moderate gales. Smooth sea and drizzling shewers. Saw three sail in the S. E. quarter. Fair weather and a fresh gale. Latitude observed at noon.	Course S. 16° W. Distance 112. Latitude per acct. Longitude made Meridian distance from the Lizard. [In this column are to be inserted, after the day's work is corrected, the course, distance, &c. opposite to the words.]	2^d Nov. 21. Strong gale and heavy sea at 1^h past 1 P. M. Close reefed. Main and fore-top-sail furled: mizen ditto. Cloudy, with rain and gleams of lightning. Storm ceases. Furled the top-sails, and got down the top-gallant yards. Very high sea breaking over the ship. Secured the boats with frappings. Violent storm. Furled the main-sail and fore-sail, and lay to under ballanced mizen. Ship labours extremely. Launched the guns over-board.	Course Distance Latitude Longitude Meridⁿ distance Drift under ballanced mizen.
3^d Nov. 20. The first part of this 24 hours, fresh gales and a clear sky, the middle and latter parts cloudy, with sprinkling rain, and a swelling sea from the N. W. The wind strengthening, reefed the top-sails. No observations to-day. At ten A. M. double reefed the top-sails.	Course Distance Latitude Longitude Meridⁿ distance	4th Nov. 22. Tempest continues, accompanied with a high and dangerous sea. Ship very leaky. At 5 P. M. a heavy sea broke aboard, and carried away the boat, and three men off the deck, and split the mizen. Brought to another and set. Ship continues very leaky. Labours and pitches excessively. At 1^h past 7 P. M. by a heavy pitch the bowsprit was carried away, which was immediately followed by the fore-mast and main-top-mast. Thunder, lightning, and meteors, at the mast-head. The storm abates. Heavy rain.	Course Distance Latitude Longitude Meridⁿ distance

Azimuths, Amplitudes, Bearings, Distances, and Variations for the four Days.

☉ This morning found the sun's azimuth by a good observation 75° 30': his altitude was then 9° 30'. The true amplitude 67° 4', which makes the variation 8° 26'.

Bearing and distance of the Lizard.

Bearing and distance of Cape Ortugal in Spain.

RECLAIMING, or **RECLAMING**, in our ancient customs, a lord's pursuing, prosecuting, and recalling his vassal, who had gone to live in another place without his permission.

RECLINER, or **RECLINING DIAL**. See the article **DIALLING**.

RECLUSE, among the papists, a person shut up in a small cell of an hermitage, or monastery, and cut off, not only from all conversation with the world, but even with the house. This is a kind of voluntary imprisonment, from a motive either of devotion or penance.

RECOGNITION, in law, an acknowledgment; a word particularly used in our law books, for the first chapter of the statute 1 Jac. I. by which the parliament acknowledged, that, after the death of queen Elizabeth, the crown had rightfully descended to king James.

RECOGNIZANCE, or **RECOGNISANCE**, in law, a bond or obligation of record, acknowledged to the king: thus called, because recognized or acknowledged in some court of record, or before some judge, master in chancery, or justice of the peace.

RECOIL, or **REBOUND**, the starting backward of a fire-arm, after an explosion.

Mersennus tells us, that a cannon 12 feet in length, weighing 6400 lb. gives a ball of 24 lb. an uniform velocity of 640 feet per second. Putting therefore, $W=6400$, $w=24$, $V=640$, and v = the velocity with which the cannon recoils; we shall have (because the momentums of the cannon and ball are equal) $Wv = wV$; and so $v = \frac{wV}{W} = \frac{24 \times 64}{6400} = 2, 4$; that is, it would recoil at the rate of $2\frac{4}{10}$ feet per second, if free to move.

RECOLLECTION, a mode of thinking, by which ideas sought after by the mind, are found, and brought again to view.

RECOLLECTS, a congregation of reformed Franciscans, called also friars-minors of St. Francis, of the strict observance. See **FRANCISCANS**.

RECONNOITRE, in war, to view and examine the state and situation of things.

RECORD, an authentic testimony in writing, contained in rolls of parchment, and preserved in a court of record.

RECORDER, a person whom the mayor and other magistrates of a city or corporation associate to them, for their better direction in matters of justice, and proceedings in law; on which account this person is generally a counsellor, or other person well skilled in the law.

RECOVERY, in law, is obtaining any thing by judgment or trial at law.

Recoveries are of two kinds, a true recovery, and a feigned or common one. A true recovery is the actual recovering of any thing, or its value, by judgment and trial at law: as where a person is sued for land, or other things real and personal, and obtains a verdict in his favour. A feigned or common recovery, is a formal act by consent, made use of for the better securing of lands, tenements, &c. the end and effect of which is, to dock and destroy estates-tail, remainders, and reversions, and to bar the former owners.

RECREMENT, in chemistry, some superfluous matter separated from some other that is useful: in which sense it is the same with scoriae, faeces, and excrements. See **SCORIAE**, &c.

RECRIMINATION, in law, an accusation brought by the accused against the accuser, upon the same fact.

RECRUITS, in military affairs, new-raised soldiers, designed to supply the place of those who have lost their lives in the service, or are disabled by age or wounds.

RECTANGLE, in geometry, the same with a right-angled parallelogram.

In arithmetic and algebra, a rectangle signifies the same with factum or product.

RECTANGLED, **RECTANGULAR**, or **RIGHT-ANGLED**, appellations given to figures and solids which have one or more right-angles: thus a triangle with one right angle, is termed a rectangled triangle; also parallelograms with right-angles, squares, cubes, &c. are rectangular.

Solids, as cones, cylinders, &c. are also said to be rectangular, with respect to their situation, when their axes are perpendicular to the plane of the horizon.

The ancient geometers always called the parabola, the rectangular section of a cone.

RECTIFICATION, the art of setting any thing to rights: and hence, to rectify the globes, is to fit them for performing any problem.

RECTIFICATION, in geometry, is the finding a right line, equal in length to a curve. See the article **CURVE**.

RECTIFICATION, in chemistry, is nothing but the repetition of a distillation, or sublimation several times, in order to render the substance purer, finer, and freer from aqueous or earthy parts.

The perfection of rectifying spirits, according to Dr. Shaw, depends upon finding out a simple method of separating all the oil and water from it; and, he observes, that the great affinity betwixt the essential oil and spirit, is the physical cause of the difficulty found in the rectification of brandies. He recommends the way of working from a spirit largely diluted with water, into water again; whereby the essential oil would, at one operation, be doubly separated.

RECTIFIER, in navigation, an instrument consisting of two parts, which are two circles either laid one upon, or let into, the other, and so fastened together in their centers, that they represent two compasses, one fixed, the other moveable; each of them divided into the thirty-two points of the compass, and three hundred and sixty degrees, and numbered both ways, from the north and the south, ending at the east and west, in ninety degrees.

The fixed compass represents the horizon, in which the north and all the other points of the compass are fixed and immoveable.

The moveable compass represents the mariners compass, in which the north and all other points are liable to variation.

In the center of the moveable compass is fastened a silk thread, long enough to reach the outside of the fixed compass. But, if the instrument be made of wood, there is an index instead of the thread.

Its use is to find the variation of the compass, to rectify the course at sea; having the amplitude or azimuth given.

RECTILINEAR, in geometry, right-lined; thus figures whose perimeter consists of right lines, are said to be rectilinear.

RECTITUDE, *Rectitudo*, in philosophy, refers either to the act of judging or of willing; and therefore whatever comes under the denomination of rectitude is either what is true or what is good; these being the only objects about which the mind exercises its two faculties of judging and willing.

RECTOR, a term applied to several persons whose offices are very different: as, 1. The rector of a parish is a clergyman that has the charge and cure of a parish, and possesses all the tythes, &c. 2. The same name is also given to the chief elective officer in several foreign universities, particularly in that of Paris. 3. Rector is also used in several convents for the superior officer who governs the house: and the Jesuits give this name to the superiors of such of their houses as are either seminaries or colleges.

RECTORY, a parish church, parsonage, or spiritual living, with all its rights, tythes, and glebes.

RECTUM, in anatomy, the third and last of the large intestines, or guts.

The rectum is in length about three hands breadth, and its diameter about three fingers. It has its beginning at the lower vertebræ of the loins, and at the lower end is the anus.

It is connected to the os sacrum, the os coccygis, and the urinary bladder in men, but in women to the vagina uteri. The coats of the rectum are more thick and fleshy than those of any other of the intestines: it has in general no valves, but it has several rugæ: the absence of valves here, is to prevent the expulsion of the faeces from being retarded.

RECTUS,

RECTUS, in anatomy, a name common to several pair of muscles, so called on account of the straightness of their fibres, as, 1. The rectus major anticus, which arises from the transverse apophyses of the five lower vertebrae of the neck, and is inserted into the os occipitis. 2. The rectus minor anticus, called, by Cowper, musculus annuens: this arises from the anterior surface of the atlas, or first vertebra of the neck; and lies concealed, as it were, under the former, till it is at length inserted a little behind it, into the os occipitis: these two pair of muscles serve to move the head forward. 3. The rectus major posticus, one of the extensors of the head, which has its origin from the spinose apophysis of the epistrophæus, and is inserted into the os occipitis. 4. The rectus minor posticus, which is also one of the five extensors of the head, has its rise from the posterior part of the atlas, and its end under the former. 5. The rectus lateralis, which serves to bend the head on one side, has its origin from the upper surface of the transverse apophysis of the atlas; from this it ascends straight with a short body, but considerably thick; and is inserted partly into the os occipitis, and partly into the temporal bone, near the incisure of the mastoide process. 6. The rectus tibiæ, one of the four extensors of the leg, which has its origin from the anterior and inferior spine of the ileum.

RECURRENTS, in anatomy, a name given to several large branches of nerves sent out by the par vagum, from the upper part of the thorax to the larynx.

RECURRENT VERSES are the same with those called reciprocal. See **RECIPROCAL**.

RECUSANTS, such persons as acknowledge the pope to be the supreme head of church, and refuse to acknowledge the king's supremacy; who are hence called popish recusants. These are in England charged with double taxes, not merely as Romanists, but as recusants.

RECUSATION, the desiring a judge to refrain from judging in a certain cause, on account of his kinship, capital enmity, &c. to one of the parties.

RED, in physics, one of the simple or primary colours of natural bodies, or rather of the rays of light. See **COLOUR**, **LIGHT**, and **RAY**.

The red rays are those which of all others are the least refrangible: hence, as Sir Isaac Newton supposes the different degrees of refrangibility arise from the different magnitudes of the luminous particles whereof the rays consist, the red rays, or red light, is concluded to be that which consists of the largest particles. Authors distinguish three general kinds of red; one bordering on the blue, as columbine, or dove-colour, purple, and crimson. Another bordering on yellow, as flame-colour and orange; and between these extremes is a medium, partaking neither of the one nor the other, which is what we properly call red. Mr. Boyle observes, that red is an obvious, and generally a pleasing colour; and that anciently it was customary to present red objects to elephants, to render them more fierce; and that the same colour irritates turkey-cocks. He observes also, that among the several changes of colour which bodies acquire, or disclose, by digestion, it is very remarkable to find a redness rather than any other colour in most tinctures; and even in the more gross solutions made of almost all concretes that abound either with mineral or vegetable sulphur, though the menstruum employed about these solutions, or tinctures, be never so limpid.

RED, in heraldry. See the article **GULES**.

RED-BOOK of the Exchequer, an ancient record or manuscript volume, in the keeping of the king's remembrancer, containing divers miscellany treatises relating to the times before the Conquest.

REDDLE, a soft, heavy red marle, of great use in colouring; and being washed and freed from its sand, is often sold by our druggists under the name of bole-armenic.

REDEMPTION, in law, a faculty or right of re-entering upon lands, &c. that have been sold and assigned, upon re-imbursing the purchase money with legal costs.

REDENS, **REDANS**, or **REDANT**, in fortification, a kind of work indented in form of the teeth of a saw, with salient and re-entering angles, to the end that one part may flank or defend another. It is called saw-work and indented work. The faces in this, flank one another.

Redens are frequently used in the fortifying of walls, where it is not necessary to be at the expence of building bastions; as when they stand on the side of a river, a marsh, the sea, &c.

REDOUBT, or **REDOUTE**, *Reductus*, in fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, contravallation, and approach, as also for the lodgings of corps de garde, and to defend passages. In marshy grounds, redoubts are frequently made of stone-works, for the security of the neighbourhood; their face consists of from ten to fifteen fathom, the ditch round them from eight to nine feet broad and deep, and their parapets have the same thickness.

REDUCT, or **REDUIT**, a military term signifying an advantageous piece of ground, entrenched, and separated from the rest of the place, camp, &c. for an army, garrison, &c. to retire to in case of a surprize.

REDUCT, in building, a quirk or little place taken out of a larger to make it more uniform and regular; or for some other convenience, as for a little cabinet aside of a chimney, for alcoves, &c.

REDUCT, or **REDUX**, among chemists, a powder by which calcined metals and minerals are again reduced to their regulus, or pure substance.

REDUCTION, *Reductio*, in the schools, a manner of bringing a term or proposition which was before opposite to some other to be equivalent to it.

REDUCTION of Syllogisms, is a regular changing or transforming of an imperfect syllogism into a perfect one; or it is a change of a syllogism in respect of form, whereby the necessity of the illation or inference is made more evident. See **SYLLOGISM**.

REDUCTION, in arithmetic, that rule whereby numbers of different denominations are brought into one denomination. Reduction is but the application of multiplication and division. For, first, a higher denomination is brought into a lower one, by multiplying the higher denomination with so many of the lower as are contained in the higher; still keeping them equivalent in value. This is called reduction descending. Secondly, a lower or inferior denomination is reduced into a higher or superior one, by dividing the lesser one with so many of its denomination as is contained in the greater. This is the converse of the last, and is termed reduction ascending. Thus pounds are reduced into shillings by multiplying with 20; shillings into pence, by multiplying with 12; and pence into farthings, by multiplying with 4. On the other hand, shillings are reduced into pounds, by dividing with 20; pence into shillings, by dividing with 12; and farthings into pence, by dividing with 4.

Examples. Let it be required to reduce 357 l. into shillings, and those shillings into pence; $357 \times 20 = 7140 =$ the shillings in 357 l. and $7140 \times 12 = 85680 =$ the pence in 357 l. as was required. Again, let it be required to reduce 85680 d. into shillings, and those shillings into pounds; $85680 \div 12 = 7140 =$ the shillings in 357 l. and $7140 \div 20 = 357 l.$ as was required.

If there remain any thing in each division, it is respectively either odd pence, shillings, or farthings; thus 4123788 farthings, being reduced, give 4295 l. 12 s. 3 d.

But when the numbers proposed to be reduced are of several denominations, and it is required to bring them all to the lowest, you must reduce, as before, the highest or greatest denomination to the next less, adding the numbers that are of that next denomination together; then reduce their sum to the next lower denomination; adding together all the numbers that are of that denomination, and so proceed gradually on until all is done.

REDUCTION of Fractions. See the article **FRACTION**.

REDUCTION of Equations, in algebra. See the article **EQUATION**.

REDUCTION of a Figure, Design, or Draught, is the making a copy thereof either larger or smaller than the original; still preserving the form and proportion. The great use of the proportional compasses is the reduction of figures, &c. whence they are called compasses of reduction.

There are various methods of reducing figures, &c. The most easy is by means of the pentagraph, or parallelogram. See **PENTAGRAPH**.

REDUCTION to the *Ecliptic*, in astronomy. The place of any star reduced to the ecliptic, is that point where the secondary passing through the star intersects the ecliptic.

REDUCTION, in metallurgy, is the bringing back metalline substances which have been changed into scorize or ashes, or otherwise divested of their metallic form, into their natural and original state of metals again.

REDUCTION, in surgery, denotes an operation whereby a dislocated, luxated, or fractured bone is restored to its former state or place. See the articles **LUXATION** and **FRACTURE**.

REDUNDANCY, or **REDUNDANCE**, a fault in discourse, consisting in the use of a superfluity of words. Words perfectly synonymous are redundant, and ought to be retrenched.

REDUNDANT HYPERBOLA, is a curve of the higher kind, thus called, because it exceeds the conic section of that name, in the number of its hyperbolical legs; being a triple hyperbola with six hyperbolical legs.

REDUPLICATION, in rhetoric, a figure whereby a verse begins with the same word as the preceding one ends with.

REDUPLICATION, in logic, a kind of condition expressed in a proposition indicating or assigning the manner wherein the predicate is attributed to the subject. Hence reduplicative propositions are such wherein the subject is repeated with some circumstance or condition. Thus, "Men, as men, are rational: kings, as kings, are subject to none but God."

REED, an ancient Jewish measure. See the article **MEASURE**.

REEF, in naval affairs, certain spaces or divisions of the sail, which are taken in, or let out, in proportion to the increase or diminution of the wind. In a square sail they are placed parallel to its upper edge, below one another, at equal distances, each reef containing about a seventh part of the sail's depth, and are thus formed: at the bottom of each division there is a row of holes stretching across the sail, through which are inserted a number of platted cords, called points, in length each about twice the circumference of the yard, and these bind the intermediate space of canvas in plaits close up to the yard, from end to end; the sail being lowered slack down for that purpose.

REEF-LINES are used to the courses only, and are passed in spiral turns through the holes of the reef, and over the head of the sail successively, till they reach the extremities of the reef, and then being hauled tight, draw it close up to the yard.

REEF-TACKLES are ropes which run through holes at each top-sail yard-end, and are fastened down on the edge or leech of the top-sail, immediately under the lowest reef. By hauling up these tackles the reef-band, which contains the holes, is bound close up to the yard, for the more readily tying the points.

REEL of the *Log*, in naval affairs, a sort of winch, or roller, containing four or five spokes, and an axis; upon which is wound the log-line, which measures a ship's way at sea. See the article **LOG**.

REEL, in the manufactories, a machine serving for the office of reeling. There are various kinds of reels, some very simple, others very complex. Of the former kinds those most in use are, 1. A little reel held in the hand, consisting of three pieces of wood, the biggest and longest whereof, which does not exceed a foot and a half in length, and $\frac{1}{4}$ of an inch in diameter, is traversed by two other pieces disposed different ways. 2. The common reel, or windlace, which turns upon a pivot, and has four flights traversed by long pins or sticks, whereon the skain to be reeled is put, and which are drawn closer or opened wider, according to the skain. A representation of the common reel may be seen in plate CIX. fig. 1. where A is the bench or seat of the reel, B the two uprights, C the arms of the reel; its arbor turning and hitching its little lantern of four notches in the teeth of the wheel. D two wheels, the upper one of which moves the lower, by means of a pinion. E a hammer, the handle whereof is lowered by a peg at the bottom of the lower wheel. F a cord which is rolled round the axle of the lower wheel,

and supports a weight which stops after a certain number of turns, to regulate the work-woman. See the article **SILK**.

REELING, in the manufactories, the winding of thread, silk, cotton, or the like, into a skain, or upon a bottom, to prevent its entangling. It is also used for the charging or discharging of bobbins or quills, to use them in the manufacture of different stuffs, as thread, silk, cotton, &c. Reeling is performed different ways and on different engines.

RE-ENTRY, in law, signifies the resuming or retaking that possession which any one had lately foregone; as where a person makes a lease of lands to another, the lessor thereby quits the possession, and if the lessee covenants that upon non-payment of the rent reserved, the lessor may lawfully re-enter, being as much as if it was conditioned for the lessor to take the land again into his hands, and recover the possession again by his own act without the assistance of the law.

REEVE of a *Church*, the guardian of it, or the churchwarden.

REEVING, in the sea-language, the act of thrusting a rope through any hole, particularly through the channels of several blocks, to form a tackle or complication of pulleys.

RE-EXCHANGE, in commerce, a second payment of the price of exchange, or rather the price of a new exchange due upon a bill of exchange that comes to be protested, and to be refunded the bearer by the drawer or indorser.

REFECTION, among ecclesiastics, a spare meal or repast just sufficing for the support of life: hence the hall in convents, and other communities, where the monks, nuns, &c. take their refectations or meals in common, is called the refectory.

REFERENCE, in writing, &c. a mark relative to another similar one in the margin, or at the bottom of the page, where something omitted in the text is added, and which is to be inserted either in reading or copying.

REFINING, in general, is the art of purifying a thing; including not only the assaying or refining of metals, but likewise the clarification of liquors.

REFINING of Gold is performed three ways, viz. either with antimony, sublimate, or aqua fortis; the last of which is the most usual, and is called depart, or quartation. To refine gold with antimony, they make use of a wind furnace, and a common crucible of a size answerable to the quantity of gold to be refined; always taking care that the gold and antimony, both together, do not fill the crucible more than half full. After the gold is melted in the crucible, the antimony is thrown in in powder: the proportion of the antimony to the gold is eight ounces to a pound, if the gold be between sixteen and twenty-two carats fine; if it be under sixteen carats, then they use five quarters of a pound to eight ounces of gold; and still the greater quantity of antimony is required, the coarser the gold is.

As soon as they have put the antimony into the crucible they cover it, and after they have charged the furnace with charcoal, they put on the capital, which is let to stand till such time as the crucible is left quite bare; then they take off the capital, and leave the crucible to cool in the furnace of itself, till such time as they can take it out by the hand; then they break it, to get out the button, or culot, which is a mass of fine gold, remaining at the bottom, with the fæces of the antimony, the silver and copper alloy, and sometimes little particles of gold itself over it.

But notwithstanding the gold thus prepared is very pure, yet the antimony gives it such a harsh brittle quality, that it ceases to be ductile, and must be softened by the fire with salt petre and borax, to bring it to itself. In order to this operation, they prepare what is called a dry-coppel, which is a coppel made of crucible earth, that does not imbibe like the coppels made of ashes. When the coppel has been sufficiently heated in the refining furnace, they put the gold into it, and cover it over with charcoal. As soon as the gold is dissolved, which is very soon, by reason of the remains of the antimony, they blow

blow it with the bellows to drive the mineral entirely away, which now goes off in smoke; and add to it, as soon as the fumes cease, a little salt-petre and borax in powder, which collect the impurities that remained upon the dissolution, and fix the gold in the coppel in the form of a plate. Then the gold is taken out of the coppel, and melted again in a crucible, with an addition of two ounces of salt-petre and borax in powder, to each eight ounces of gold, as soon as it has ceased to fume; and then it is cast into an ingot, which upon trial is found to be twenty-three carats, twenty-six thirty seconds fine.

The particles of gold, detained with the alloy in the faces of the antimony, are got out by a dry coppel, with the same meltings and ingredients, as were used in softening the former: and when they are certain, by the assay, how much gold that matter contains, they refine it to separate the copper, and afterwards make the depart or quartation.

As for the gold which may be left sticking to the dry coppels, it is got by breaking and pulverizing the crucibles, and by repeated washings of the powder of them. The method of refining gold by means of sublimate is this; they begin the process like that with antimony; that is, in the same furnace, with the same coal, the same fire, and the same crucibles. When the gold is melted in the crucible, they cast in the sublimate, not in powder, but only broken into pieces: the proportion is, if the gold be of twenty-two carats, an ounce or an ounce and a half, or even two ounces of the sublimate to eight ounces of the gold; if of twenty carats, three ounces; and if it be only from eighteen to twelve, five or six ounces of the sublimate to eight of the gold, in which last case they part the sublimate into two, and put in one half at a time with the gold into a new crucible; which, when the operation is over, leaves the gold of eighteen or twenty carats, according as it was in fineness before. This done, they put the broken sublimate into a crucible with the melted gold, covering it immediately to smother the mineral; and then fill the furnace with charcoal, having first put on the capital; after a quarter of an hour they take off the capital, lay the crucible bare, and blow off all the ashes and other impurities, that may be floating on the liquid gold, with a pair of bellows. This is repeated again, till the impurities of the gold are carried off by the sublimate appearing of a bright glittering colour; after which being taken out of the crucible, it is cast into an ingot.

This method of refining by sublimate, is both cheaper and more complete than that by antimony; but they are both exceeding dangerous, by reason of the sulphureous and arsenical exhalations; on which account the method of quartation is most practised.

REFINING of Silver is performed two ways; one with lead, and the other with salt-petre.

In order to refine silver with lead, a coppel is filled with a mixture of brick-ashes and ashes of bullocks and other bones.

It is set on the fire, and heated red-hot, in which state the silver and lead are put in together, in the proportion of a pound of lead to eight ounces of silver, and even somewhat more lead, if the silver be very coarse.

As these two metals melt together, the copper before mixed with the silver dissipates into smoke, or goes away with the scum; and so does the lead itself, leaving the silver alone in the coppel in its proper degree of fineness.

In this method of refining, wherein six or seven thousand pounds may be refined at once, the metal is drawn out of the coppel two ways; the one by plunging in it, while still liquid, a thick bar of iron, round which the silver sticks in form of a shell or crust, repeating this again and again; the other is by letting the coppel stand till it is cold; in the bottom of which, the silver fixes in form of a cake.

This method of refining silver with lead, is both the best and the cheapest; however, for want of workmen who understand it, that with salt petre still obtains in many places; which is performed in a wind furnace. They first reduce the silver to be refined into grains, about the size of a small pea; which is done by first melting it, then throwing it into a tub of common water, and then heating it over again in a boiler. This being done, they put

it into a crucible; putting to every eight ounces of silver two of salt-petre. Then they cover the crucible with an earthen lid, in the form of a dome, exactly luted; which lid, however, must have a little aperture in the middle. The crucible being set into the furnace, and covered with charcoal, which is only to be lighted by degrees, at length they give it the full force of the fire, to put the metal into a perfect fusion. This is repeated three times successively, at an interval of a quarter of an hour. After the third fire they uncover the furnace, and let the crucible cool; and at length break it, to get out the silver, which is found in a button or culot, the bottom of which is very fine silver; and the top mixed with the faces of the salt-petre, and the alloy of the silver, and even some particles of fine silver. Then they separate the culot from the impurities, and melt it in a new crucible; and throw charcoal-dust into the dissolution, and work the whole briskly together. Then they cover the crucible up again, charge the furnace with coal, and give it a second fire.

Having done this, they blow off the ashes and impurities with bellows, from off the top of the metal, till it appears as clear as a looking-glass; and then they throw in an ounce of borax broken to pieces. Then, in the last place, they cover the crucible up again, and give it the last fire, and after this cast it into ingots, which are found eleven penny weight and sixteen grains fine. To recover the silver that may be left in the faces and scoria, they pound them, and give them repeated lotions in fresh water.

REFINING of sugar, sulphur, camphor, &c. See SUGAR, CAMPHOR, &c.

REFLECTING, or REFLECTIVE DIAL. See DIALLING.

REFLECTION, or REFLEXION, in mechanics, the return or regressive motion of a moving body, occasioned by some obstacle which hindered it from pursuing its former direction.

REFLECTION, in catoptrics, is the return of a ray of light from the polished surface of a speculum or mirror.

The ray, thus returned, is called a reflex, or reflected ray, or ray of reflection; and the point of the speculum, whence the return commences, the point of reflection.

Thus, the ray AB (plate CIX. *fig. 2.*) proceeding from the radiant A , and striking on the point of the speculum B , being returned thence to C ; BC represents the reflected ray, and B the point of reflection; in respect whereof AB represents the incident ray, or ray of incidence, and B the point of incidence.

Again, a line, as CG , drawn from any point, as C , of the reflected ray BC , perpendicular to the speculum, is called the cathetus of the reflection, or cathetus of the eye; as a line AF , drawn from the radiant, perpendicular to the speculum, is called the cathetus of incidence.

Of the two angles which the reflected ray BC makes with the mirror, the smallest, CBE , is called the angle of reflection; as, of the two angles the incident ray makes with the speculum, the smallest, ABD , is called the angle of incidence.

If the mirror be either concave or convex, the smallest angles the ray makes with a tangent to the point of reflection and incidence, are the angles of reflection and incidence.

The angle CBH , which the reflected ray makes with a perpendicular to the point of reflection, is called the inclination of the reflected ray; as the angle ABH is called the inclination of the incident ray.

General Rules of REFLECTION. — 1. If a ray of light be reflected from a speculum of any form, the angle of incidence is ever equal to the angle of reflection. This law obtains in percussions of all kinds of bodies, and, consequently, must do so in those of light.

It might, therefore, be here assumed as an axiom; but it is of that importance, and its demonstration so beautiful, that we cannot omit it. Suppose then DC (*fig. 3.*) an incident ray, propagated from the radiant A : Here, though the motion of the ray be simple, yet its determination in the line DC , being oblique with respect to the obstacle, is really compounded of two de-

termini-

terminations; the one along D E, the other along D G. The force along D C, therefore, is equal to the two forces along D G and D H; but the obstacle G F only opposes one of the determinations, viz. that along D G (for it cannot oppose a determination parallel to itself, as D E;) therefore only the force along D G will be lost by the stroke; that along D H or G C remaining entire. But a body perfectly elastic (such as we suppose the ray of light) will recover, by its elasticity, the force it lost by the shock.

The ray, therefore, will recover the force D G or C H: thus, retaining both its forces, and both its former determinations, H C and C F, after percussing, it will be impelled along C F and C H, by the same forces as before along D H and D G, by its compound motion; therefore it will describe the right line C E, and that in the same time as D C; and H E and D H will be equal, as being described by the same force. Now, the two triangles D C H and C H E are equal, and consequently, their similar angles equal; since then $H C A = H C F$; D C A, the angle of incidence, is equal to E C F, the angle of reflection. Q. E. D.

This law is confirmed in light by an easy experiment; for the ray of the sun falling on a mirror in a dark room, through a little hole, you will have the pleasure to see it rebound, so as to make the angle of reflection equal to that of incidence. The same may be shewn various other ways: thus, e. gr. placing a semi-circle F i G, (fig. 4.) on a mirror D E, its center on B, and its limb perpendicular to the speculum; and assuming equal arches, F a and G e, place an object in A, and the eye in C, then will the object be seen by a ray reflected from the point B, and if B be covered, the object will cease to be seen.

Hence, 1. If a ray of light, as H B, fall perpendicularly on the surface of a speculum D E, it will be reflected back upon it.

2. From the same point of a speculum several rays cannot be reflected to the same point; for in that case all the several angles of reflection would be equal to the same angle of incidence, which is absurd.

3. One ray, as A B, cannot be reflected to two or more points; for in that case all its angles of reflection would be equal to the same angle of incidence; which is as absurd as before.

2d. Each point of a speculum reflects rays falling on it from each part of an object.

Hence, since several rays, coming from several parts of a radiant object, cannot be reflected from the same point of a speculum to the same point; the rays that flow from different points of the object are separate after reflection: and hence each ray shews the point whence it proceeded.

On this principle it is, that the rays reflected from mirrors or looking-glasses, exhibit the appearances of objects placed before them.

And hence we easily conceive, why rough bodies exhibit images, in regard they reflect the light in such manner as to confound rays which proceed from different points, by means of their eminencies and cavities, their alternate risings and fallings: But for this, all hard bodies would be mirrors.

3d. If the eye C and the radiant point A change places, the point will continue to radiate upon the eye, in the same course or path as before.

For if the object be removed from A to C, it will still radiate on its former point of reflection B; but there can be but one right line drawn between the two points C and D, and the rays are right lines; therefore, that which was before the ray of reflection, will now be the ray of incidence; and, since it will be reflected under the same angle as that under which it fell, that which was before the ray of incidence, will now be the ray of reflection; so that the object, removed to C, will radiate on the eye, placed in A, by the right lines C D and B A.

Hence, an object is seen by the reflected ray A B, with the eye placed in A, the same as if the eye were in A C, and the object in A.

The truth of this theorem is so easily confirmed by experiment, that some, with Euclid, assume it as a prin-

ciple, and demonstrate the great law of reflection therefrom. Thus, suppose the angle of incidence a little greater than the angle of reflection, then will the angle A B F be greater than that C B E; wherefore, changing the places of the eye and the object, the angle C B E will become the angle of incidence; and, therefore, C B E greater than A B F, by the supposition; so that the same angle A B F will be greater and smaller than the other C B E; which, being allowed, A B E cannot be greater than C B E, and the same absurdity will follow if it be supposed less, therefore it must be equal to the angle of reflection C B E.

4th. The plane of reflection, that is, the plane wherein the incident and reflected ray are found, is perpendicular to the surface of the speculum, and in spherical specula passes through the center.

5th. The image of an object seen in a mirror, is in the cathetus of incidence.

This holds good, universally, in plane and spherical mirrors, and usually in concave ones, a few instances only excepted, as is shewn by Kepler. For the particular laws of reflection, arising from the circumstances of the several kinds of specula, or mirrors, plane, concave, convex, &c. see MIRROR.

REFLECTION is also used, figuratively, for an operation of the mind; whereby it turns its view backwards as it were upon itself, and makes itself and its own operation the object of its disquisition; and by contemplating the manner, order, and laws, which it observes in perceiving ideas, comparing them together, reasoning, &c. it frames new ideas of the relations discovered therein.

REFLEX, or REFLECT, in painting, is understood of those places in a picture which are supposed to be illuminated by a light reflected from some other body, represented in the same piece.

REFLEX VISION, that performed by means of reflected rays, as from mirrors.

REFLUX of the Sea, the ebbing of the water, or its returning from the shore. See TIDE.

REFORM, a re-establishment, or revival of formerly neglected discipline, or a correction of the reigning abuses therein.

To REFORM, in a military sense, is to reduce a company, regiment, &c. either by disbanding the whole, or breaking a part, and retaining the rest.

REFORMADO, or REFORMED OFFICER, one whose troop, or company, is suppressed in a reform, and he continued either in the whole or half-pay, doing duty in the regiment.

REFORMATION, the act of reforming or correcting an error or abuse in religion, discipline, or the like.

The Reformation, so called by way of eminence, is the separation of the protestants from the church of Rome, in the beginning and towards the middle of the sixteenth century. See LUTHERANS, &c.

REFRACTED, or REFRACTIVE DIAL, one that shews the hours by means of some refractive transparent fluid. See DIALLING.

REFRACTION, in mechanics, the deviation of a moving body from its direct course, by reason of the different density of the medium it moves in; or a flexion and change of direction, occasioned by a body's falling obliquely out of one medium into another of a different density.

REFRACTION of Light, in optics, is an inflexion or deviation of the rays of light from their rectilinear course, upon falling obliquely out of one medium into another of a different density.

Whatever substance a ray of light passes through, or if it pass through a space void of all substance; it is said, by philosophers, to pass through a medium; and, therefore, if it passes out of any substance, as in air or glass, into a vacuum, or the contrary, it is said to pass out of one medium into another.

All bodies being endued with an attractive force, which is extended to some distance beyond their surfaces; when a ray of light passes out of a rarer into a denser medium, if this latter has a greater attractive force than the former, as is commonly the case, and what we shall hereafter always suppose, unless it be mentioned to the contrary, the ray, just before its entrance, will be-

gin to be attracted towards the denser medium, and this attraction will continue to act upon it till some time after it has entered the medium, as we shall shew presently; therefore, if a ray approaches a denser medium in a direction perpendicular to its surface, its velocity will be continually accelerated during its passage through the space in which that attraction exerts itself; and, therefore, after it has passed that space, it will move on till it arrives at the opposite side of the medium, with a greater degree of velocity than it had before it entered. So that, in this case, its velocity only will be altered. Whereas, if a ray enters a denser medium obliquely, it will not only have its velocity augmented thereby, but its direction will become less oblique to the surface, just as, when a stone is thrown downwards obliquely from a precipice, it falls to the surface of the ground in a direction nearer to a perpendicular one, than that with which it was thrown by the hand. From hence we see that a ray of light, in passing out of a rarer into a denser medium, is refracted towards the perpendicular; that is, supposing a line drawn perpendicularly to the surface of the medium, through the point where the ray enters, and extended both ways, the ray in passing through the surface is refracted or bent towards the perpendicular line; or, which is the same thing, the line which it describes by its motion after it has passed through the surface, makes a less angle with the perpendicular, than the line it described before. All which may be illustrated in the following manner.

Let us suppose, first, that the ray passes out of a vacuum into the denser medium *ABCD* (plate *CIX. fig. 5.*) and that the attractive force of each particle in the medium is extended from its respective center to a distance equal to that which is between the lines *AB* and *EF*, or *AB* and *GH*, and let *KL* be the path described by the ray of light in its progress towards the denser medium. This ray, when it arrives at *L*, will enter the attractive forces of those particles which lie in *AB*, the surface of the denser medium, and will therefore cease to proceed any longer in the right line *KL*, but will be diverted from its course by being attracted towards the line *AB*, and will begin to describe the curve *LN*, passing through the surface *AB* in some new directions as *OQ*, thereby making a less angle with a line as *PR* drawn perpendicularly through the point *N*, than it would have done, had it proceeded in its first direction *KL*.

Farther, whereas we have supposed the attractive force of each particle to be extended thro' a space equal to the distance between *AB* and *EF*, it is evident the ray, after it has entered the surface, will still be attracted downwards till it has arrived at the line *EF*; for, till that time, there will not be so many particles above it, which will attract it upwards, as below, that will attract it downwards. So that after it has entered the surface at *N*, in the direction *OQ*, it will not proceed in that direction, but will continue to describe a curve, as *NS*, after which it will proceed straight on towards the opposite side of the medium, being equally attracted every way; and, therefore, will at last proceed in the direction *XS*, still nearer the perpendicular *PR* than before.

Now if we suppose the space *ABYZ* not to be a vacuum, but a rarer medium than the other, the case will still be the same; but the ray will not be so much refracted from its rectilinear course, because, the attraction of the particles of the upper medium being in a contrary direction to that of the attraction of those in the lower one, the attraction of the denser medium will, in some measure, be destroyed by that of the rarer.

On the contrary, when a ray passes out of a denser into a rarer medium, if its direction be perpendicular to the surface of the medium, it will only lose somewhat of its velocity, in passing through the space of attraction of that medium, that is, the space wherein it is attracted more one way than it is another. If its direction be oblique, it will continually recede from the perpendicular during its passage, and by that means have its obliquity increased, just as a stone, thrown up obliquely from the surface of the earth, increases its obliquity all the time it rises. Thus, supposing the ray *TS* passing out of the

denser medium *ABCD* into the rarer *ABYZ*, when it arrives at *S*, it will begin to be attracted downwards, and so will describe the curve *SNL*, and then proceed in the right line *LK*, making a larger angle with the perpendicular *PR*, than the line *FSX*, in which it proceeded during its passage through the other medium. The space through which the attraction of cohesion of the particles of matter is extended is so very small, that in considering the progress of a ray of light out of one medium into another, the curvature it describes in passing through the space of attraction is generally neglected, and its path is supposed to be bent, or, in the usual terms, the ray is supposed to be refracted only in the point where it enters the denser medium.

Now the ray which a line describes, before it enters a denser or rarer medium, is called the incident ray; that which it describes after it has entered, is the refracted ray.

The angle comprehended between the incident ray and the perpendicular, is the angle of incidence; and that between the refracted ray and the perpendicular, is the angle of refraction.

There is a certain and immutable law or rule, by which refraction is always performed, and that is this; whatever inclination a ray of light has to the surface of any medium before it enters it, the degree of refraction will always be such, that the proportion between the sine of the angle of its incidence, and that of the angle of its refraction, will always be the same in that medium.

To illustrate this, let us suppose *ABCD* (*fig. 6.*) to represent a rarer, and *ABEF* a denser medium; let *GH* be a ray of light passing through the first, and entering the second at *H*, and let *HI* be the refracted ray; then supposing the perpendicular *PR* drawn through the point *H*, on the center *H*, and with any radius describe the circle *APBR*, and from *G* and *I*, where the incident and refracted rays cut the circle, let fall the lines *GK* and *IL* perpendicularly upon the line *PR*, the former of these will be the sine of the angle of incidence, the latter of refraction. Now, if, in this case, the ray *GH* is so refracted at *H*, that *GK* is double or treble, &c. of *IL*, then, whatever other inclination the ray *GH* might have had, the sine of its angle of incidence would have been double or treble, &c. to that of its angle of refraction. For instance, had the ray passed in the line *MH* before refraction, it would have passed in some line, as *HN* afterwards, so situated, that *MO* should have been double or treble, &c. of *NQ*.

When a ray passes out of a vacuum into air, the sine of the angle of incidence is found to be to that of refraction, as 100036 to 100000.

When it passes out of air into water, as about 4 to 3.

When out of air into glass, as about 17 to 11.

When out of air into a diamond, as about 5 to 2.

REFRACTION, in astronomy, is an inflection of the rays of light issuing from a heavenly body, in passing through the atmosphere of the earth, whereby the apparent altitude of it is increased.

If we imagine the atmosphere to be divided into any number of concentric spherical spaces of different distances, for example, into four, as is done in plate *CIX. fig. 7.* by a like number of spherical surfaces, a ray of light coming from a star at *A*, would proceed in a straight line till it falls upon the outward surface at *B*; there it would be a little bent, and go on from thence in a straight line to *C*, where falling upon a surface of thicker air, it would receive a greater refraction, and go on in the straight line *CD*; at *D*, still thicker air would give it a new and greater refraction, into the line *DE*; at *E* the air being more dense, would give it the greatest refraction, into the line *EF*: As all vision is made in a right line, a spectator upon the earth at *F* would see the star in the line *FE* continued; so that its refracted or apparent place is *G*, higher or nearer to the zenith than its true place *A*: refraction, therefore, makes all the heavenly bodies appear higher than their true places.

If, instead of four, we imagine the atmosphere to be divided into an infinite number of spherical spaces, containing air of different densities, it is easy to see, that

K

instead

instead of going into four several straight lines, a ray of light passing through the atmosphere, will go in a curve line, whose curvature continually increases till it falls upon the earth, as is represented by the curve A B C D, fig. 8.

If a star be in the zenith of a spectator upon the earth, a ray, coming from it to his eye, falls perpendicularly upon the spherical surface of the atmosphere, and will, therefore, proceed in a straight line, without being refracted. If a star be in the horizon of an observer, a ray, coming from it to his eye, suffers the greatest refraction of all, for two reasons; 1st, The ray falls upon the surface of the atmosphere with the greatest obliquity. 2dly, It passes through the largest space of the lower and denser part of the air; thus, let A B C, (plate CIX. fig. 9) be part of the surface of the earth, B the place of an observer; if a star be in the zenith at Z, the line Z B, drawn from the star to the eye, falls perpendicular upon the spherical surface of the atmosphere at F, and, consequently, will be perpendicular to all the concentric spherical surfaces which we can imagine in the atmosphere: If a star be in his horizon at G, the ray G D, by which the star is seen, falls more obliquely upon the atmosphere at D, than the ray H E from a star at H does at E; or than a ray coming from any star between G and Z to the eye at B; moreover, the line D B is longer than F B, or E B, or than any other line which can be drawn from the outside of the atmosphere to the eye at B, between D B and F B.

The refractions of the heavenly bodies, as the sun, moon, and stars, at all altitudes except very small ones, will be nearly as the tangents of their apparent zenith distances, drawn into the respective density of the atmosphere at the places and times for which such refractions are to be determined; and therefore, if the density be the same, are simply as the tangent of their apparent zenith distances. But at very small altitudes the refractions may be found by this general rule:

As 1 to .9986, so is the sine of any given apparent zenith distance, to the sine of an arch; $\frac{1}{11}$ of the difference of which arch and the given zenith distance is the refraction sought, which for an altitude of 5° , will come out $9' 10''$; and in this manner were the two following tables computed by the late Mr. Thomas Simpson, founded upon numbers which were deduced from observations communicated to the author by Dr. Bevis; the first adapted to the mean density of the atmosphere, and the other to serve when the refractions are the greater.

REFRACTION of *Altitude* is an arch of a vertical circle, whereby the altitude is increased by the refraction.

REFRACTION of *Declination* is an arch of a circle of declination, whereby the declination of the object is either increased or diminished by the refraction.

REFRACTION of *Longitude* is an arch of the ecliptic, whereby the longitude of the object is increased or diminished by the refraction.

REFRACTION of *Latitude* is an arch of a circle of latitude, whereby the latitude of a heavenly object is either increased or diminished by its refraction.

REFRACTION in *Island Crystal*. There is a double refraction in this substance, contrary ways, whereby not only oblique rays are divided into two, and refracted into opposite parts, but even perpendicular rays, and one half refracted.

REFRIGERATIVE, in medicine, a remedy which refreshes the inward parts, by cooling them, as clysters, ptisans, &c.

REFRIGERATORY, in chemistry, a vessel filled with cold water, through which the worm passes in distillations; the use of which is, to condense the vapours as they pass through the worm.

REFUGE, a sanctuary or asylum.

REFUGEES, French Protestants, who by the revocation of the edict of Nantz, have been constrained to fly from persecution, and take refuge in foreign countries.

REGAL, or ROYAL, something belonging to a king. See ROYAL.

REGALIA, in law, the rights and prerogatives of a king; which, according to civilians, are six, viz. 1. the power of judicature: 2. the power of life and death: 3. the power of peace and war: 4. a right to such goods as have no owner, as waifs, estrays, &c. 5. assessments; and 6. the coinage of money.

REGALIA is also used for the apparatus of a coronation, as the crown, the sceptre with the cross, that with the dove, St. Edward's staff, the globe, and the orb with the cross, four several swords, &c.

REGALIA of the Church, are the rights and privileges which cathedrals, &c. enjoy by the grants of kings; and this term is particularly used for such lands and hereditaments as have been given by kings to the church.

REGARD of the Forest, the inspection or oversight thereof, or the office and province of the regarder. See REGARDER.

REGARDANT, in heraldry, signifies looking behind, and is used for a lion, or other beast, with his face turned towards his tail.

REGENERATION, in theology, the act of being born again by a spiritual birth, or the change of heart and life, experienced by a person who forsakes a course of vice, and sincerely embraces a life of virtue and piety.

REGENT, one who governs a kingdom during the minority or absence of the king.

REGICIDE, KING-KILLER, a word chiefly used with us in speaking of the persons concerned in the trial, condemnation, and execution of king Charles I.

REGIMEN, the regulation of diet, and in a more general sense, of all the non-naturals, with a view to preserve or restore health.

Dr. Mead observes, with respect to regimen, that diseases from inanition are generally more dangerous than those which proceed from repletion, because we can more expeditiously diminish than increase the juices of the body. Upon this account, though temperance is beneficial to all men, the ancient physicians advised persons in good health to indulge a little now and then, by eating and drinking more plentifully than usual: but of the two, intemperance in drinking is safer than in eating; and if a person has committed excess in the latter, cold water drank upon a full stomach will help digestion; to which it will be of service to add lemon-juice or elixir of vitriol, if he has eaten high seasoned things, rich sauces, &c. Then let him sit up for some time, and afterwards sleep. But if a man happens to be obliged to fast, he ought to avoid all laborious work. From satiety it is not proper to pass directly to sharp hunger, nor from hunger to satiety; neither will it be safe to indulge absolute rest immediately after excessive labour, nor suddenly to fall to hard work after

after long idleness. In a word, all changes in the way of living should be made by degrees. It is also beneficial to vary the scenes of life, to be sometimes in the country, sometimes in town; to go to sea, to hunt, to be at rest now and then, but more frequently to use exercise, and a moderate sleep.

The softer and milder kinds of aliment are proper for children, and for youths the stronger. Old people ought to lessen the quantity of their food, and increase that of their drink. But yet some allowance is to be made for custom, especially in the colder climates, like ours; for as in these the appetite is keener, so is the digestion better performed.

In the summer, says Dr. Brookes, when the spirits and fluid parts are apt to evaporate, the aliment should be light, moist, fluid, and easy of digestion, to repair the loss with the greater speed: and as digestion depends in part on the due preparation of the aliments, it is necessary to chew them well, especially if they are hard, that they may be the more intimately mixed with the saliva; for those who eat in a hurry, without much chewing, are very subject to indigestions.

It is well known, the cold stops the pores, and diminishes perspiration. To shun this inconvenience, it will be necessary to put on winter garments pretty early, and to leave them off late, and not to pass too suddenly from a hot into a cold air, and to avoid drinking any thing cold, when the body is hot, or when a person has been for some time speaking in public.

In short, the passions and affections of the mind produce very sensible effects. Joy, anger, fear, and sorrow, are the principal. In the first, the spirits are hurried with too great vivacity; in fear or dread, they are as it were, curbed and concentrated; and continual sorrow and anguish of mind render the fluids of the body thick, and the blood unapt for a due circulation, whence proceed many chronic diseases: it is therefore, on all accounts, as much our interest as our duty, to keep the passions within due bounds, and to preserve an inward serenity, calmness and tranquility.

REGIMEN, in chemistry, signifies the due regulation of fire. See FIRE.

REGIMEN, in grammar, that part of syntax, or construction, which regulates the dependency of words, and the alterations which one occasions in another.

REGIMENT, in war, is a body of men, either horse or foot, commanded by a colonel.

REGION, in geography, a large extent of land, inhabited by many people of the same nation, and inclosed within certain limits or bounds.

REGION, in physiology, is taken for a division of our atmosphere, which is divided into the upper, middle, and lower regions. See ATMOSPHERE.

Æthereal REGION, in cosmography, is the whole extent of the universe, in which is included all the heavenly bodies, and even the orb of the fixed stars. See the article ÆTHER.

Elementary REGION, according to the Aristotelians, is a sphere terminated by the concavity of the moon's orb, comprehending the atmosphere of the earth.

REGION, in anatomy, a division of the human body, otherwise called cavity, of which anatomists reckon three, viz. the upper region, or that of the head; the middle region, that of the thorax or breast; and the lower, the abdomen, or belly.

REGISTER, a public book, in which is entered and recorded memoirs, acts, and minutes, to be had recourse to occasionally, for knowing and proving matters of fact.

REGISTER is also used for the clerk or keeper of a register.

REGISTER, in printing, is disposing of the forms on the press, so as that the lines and pages printed on one side of the sheet, fall exactly on those of the other.

REGISTER, among letter-founders, is one of the inner parts of the mould, in which the printing-types are cast.

REGISTERS, in chemistry, are holes, or chinks with stopples, contrived in the sides of furnaces, to regulate the fire; that is, to make the heat more intense, or

remiss, by opening them to let in the air, or keeping them close to exclude it.

REGLET, or RIGLET, in architecture, a flat narrow moulding, used chiefly in pannels and compartments, to separate the parts or members from one another, and to form knots, frets, and other ornaments.

REGLETS, or RIGLETS, in printing, are thin slips of wood, exactly planed to the size of the body of the letter.

REGRATOR, or REGRATER, in law, formerly signified one who bought wholesale, or by the great, and sold again by retail: but the term is now used for one who buys any wares or victuals, and sells them again in the same market, or fair, or within five miles round it.

REGULAR, the relation of any thing conformable to the rules of art.

REGULAR Figure, in geometry, a figure both equilateral and equiangular.

REGULAR, or Platonic Body, a solid terminated on all sides by regular, similar, and equal planes, and whose solid angles are all equal. The solid bodies are the five following: 1. The tetrahedron, which is a pyramid, comprehended under four equal and equilateral triangles. 2. The hexahedron, or cube, whose surface is composed of six equal squares. 3. The octahedron, which is bounded by eight equal and equilateral triangles. 4. The dodecahedron, which is contained under twelve equal and equilateral pentagons. 5. The icosihedron, consisting of twenty equal and equilateral triangles. These five are all the regular bodies in nature.

The proportion of the five regular bodies inscribed in the same circle from Peter Aërigon. Cursus Math. vol. I. p. 779. and Barrow's Euclid, lib. XIII.

The diameter of the sphere being 2.	
The circumference of the greatest circle	6.28318
Superficies of the greatest circle	3.14159
Superficies of the sphere	12.56637
Solidity of the sphere	4.1879
Side of the tetrahedron	1.62299
Superficies of a tetrahedron	4.6188
Solidity of a tetrahedron	0.15132
Side of a cube or hexahedron	1.1547
Superficies of the hexahedron	8.
Solidity of the hexahedron	1.5366
Side of an octahedron	1.41421
Superficies of the octahedron	6.9282
Solidity of the octahedron	1.33333
Side of the dodecahedron	0.71364
Superficies of the dodecahedron	10.51462
Solidity of the dodecahedron	2.78516
Side of the icosihedron	1.05146
Superficies of the icosihedron	9.57454
Solidity of the icosihedron	2.53615

If one of these five regular bodies were required to be cut out of the sphere of any other diameter, it will be as the diameter of the sphere 2 is to the side of any one solid inscribed in the same (suppose the cube 1.1547) so is the diameter of any other sphere (suppose 8) to 9.2376, the side of the cube inscribed in this latter sphere.

Let dr (plate CIX. fig. 10.) be the diameter of any sphere, and $da\frac{1}{2}$ of it $= ab = br$. Erect the perpendiculars ae , ef , and bg , and draw de , df , er , fr , and gr . Then will

1. re be as the side of the tetrahedron.
2. df is the side of the hexahedron.
3. de is the side of the octahedron.
4. Cut de in extreme and mean proportion in b , and db will be the side of the dodecahedron.
5. Set the diameter dr up, perpendicularly, at r , and from the center c , to its top, draw the line cg , cutting the circle in g . Let fall the perpendicular gb ; then is br the side of the icosihedron.

REGULAR Curves, such as proceed gradually in the same geometrical manner, with regard to their curvities.

REGULAR, in a monastery, a person who has taken the vows.

REGULAR Priest, a priest in some religious order; in contradistinction to a secular priest, or one that lives in the world at large.

REGULATOR of a watch, the small spring belonging to the ballance; serving to adjust its motions, and make it go faster or slower.

REGULUS, in chemistry, an imperfect metallic substance, that falls to the bottom of the crucible, in the melting of ores, or impure metallic substances.

REGULUS, in astronomy, a star of the first magnitude, in the constellation Leo, called also from its situation, *cor Leonis*, or the lion's heart. See **LEO**.

REHEARSAL, in music, and the drama, an essay or experiment of some composition generally made in private, previous to its representation or performance in public, in order to render the actors and performers more perfect in their parts.

REIMBURSEMENT, in commerce, the act of repaying another the expences he has been at on our account.

REIN-DEER, in zoology, a species of the cervus, with horns ramose and cylindric, with their tops pal-
mated.

This is a large and beautiful species, not inferior to the elk in size or strength, but greatly exceeding it in form; it is of the size of a small horse, but its shape is exactly that of the red-deer. It is a native of the northern regions, there being no country so far north as not to afford it, where it is of vast use to the inhabitants, as a beast of draught.

REINFORCED, or **REINFORCED RING**, of a cannon, is the next after the trunnions, betwixt them and the touch-hole.

REINFORCEMENT, in war, a fresh supply of men, arms, ammunition, &c.

REINS, in anatomy, the same with the kidneys. See **KIDNEYS**.

REJOINTING, in architecture, filling up the joints of the stones in buildings.

REJOYNDER, or **REJOINDER**, in law, is the defendant's answer to the plaintiff's replication or reply.

RELAPSE, a falling again into a danger, evil, or disease, from which a person has escaped.

RELATION, *Relatio*, in philosophy, the mutual respect of two things, or what each is with regard to the other.

Relations make the largest class of our perceptions, since every single object admits of almost innumerable comparisons with others: thus, if we compare one thing with another in respect of bulk, we get the ideas of greater, less, or equality; if in respect of time, of older and younger; and so for other relations, which we can pursue at pleasure, almost without end; whence it is easy to conceive, how very extensive this tribe of our perceptions must be. However, here, as well as in the other kinds of our complex ideas, we bound ourselves for the most part to such comparisons, as the exigencies of society, the wants of life, and the different professions of men render necessary; and are more or less accurate in tracing out the relations of things, according to the degree of importance they appear to have in these respects.

The relations of men one to another, arising either from the ties of blood, their several ranks and places in the community, or a mutual intercourse of good offices, being of great weight and concern in the commerce of life, have in a particular manner engaged our attention, and are therefore very minutely described. For the same reason men have found it necessary to determine as exactly as possible, the various dependence of things, as their happiness is nearly connected with this knowledge. When we consider objects merely in respect of existence, as either giving or receiving it, we come by the relative ideas of cause and effect, which are very nearly connected with the welfare of mankind; it being evident, that the several schemes and purposes of life are all conducted upon a previous supposition, that certain known causes will have their usual regular effects, and such and such actions be attended with such and such consequences.

But there are other relations of this kind, as when we also take in the additional gifts of a capacity for happiness, and the means of attaining it; which constitutes the relation of creator and creature, in the more solemn acceptation of these words. Again, when we consider

the great Author of our being, not only as the creator of the universe, but also as preserving and holding it together, and presiding over the present frame of things with uncontrouled dominion; he then appears under the notion of a moral governor, to whom we are accountable for our actions, and the use we make of those powers and faculties we derive from him. And thus we may, in some measure, perceive, how the mind proceeds in comparing its ideas together, and by what views it is chiefly governed in framing the compound notions of this class, by which it represents the various habitudes of things.

Moral actions are nothing but relations, it being their conformity or disagreement with some rule that makes them either good or bad, or indifferent; and indeed, we ought carefully to distinguish between the positive idea of the action, and the reference it has to a rule.

RELATION, in geometry, signifies the same with ratio.

RELATION, in grammar, is the correspondence which words have to one another in construction.

RELATIVE, something relating to, or respecting, another.

RELATIVE TERMS, in logic, are words which imply a relation: such as master and servant, husband and wife, &c.

RELAY, a supply of horses placed on the road, and appointed to be ready for a traveller to change, in order to make the greater expedition.

RELAY, in tapestry, is an opening left, where the colours and figures are to be changed, when the piece is finished.

RELEASE, in law, is an instrument in writing by which estates, rights, titles, entries, actions, and other things are extinguished and discharged; and sometimes transferred, abridged, or enlarged: and, in general, it signifies one person's giving up or discharging the right or action he has, or claims to have, against another, or his lands, &c.

RELEGATION, a kind of banishment or exile, in which a person is sentenced to retire to a certain place prescribed, and to continue there a certain time, or till he is recalled.

RELICS, in the Romish church, the remains of the bodies or cloaths of saints or martyrs, and the instruments by which they were put to death, devoutly preserved, in honour to their memory; kissed, revered, and carried in procession.

RELICT, in law, the same with widow. See the article **WIDOW**.

RELIEVE, in a military sense, is to send off those men that are upon duty, and to bring others to take their place: thus, to relieve the guard, the trenches, &c. is to bring fresh men upon duty, and to discharge those who were upon duty before.

RELIEVING - TACKLES, in naval affairs, two strong purchases passing under the bottom of a ship when she is laid on a careen, to bring her upright again, when it may be difficult to right her without them. They are passed under the keel, and fastened to the upper part of the opposite side, or the side farthest from the shore, or wharf, where the careen tackles are fastened.

RELIEVO, or **RELIEF**, in sculpture, &c. is the projection or standing out of a figure, which arises prominent from the ground or plan on which it is formed; whether that figure be cut with the chisel, moulded or cast.

There are three kinds or degrees of relievo, viz. alto, basso, and demi-relievo. The alto-relievo, called also haut-relief or high relievo, is when the figure is formed after nature, and projects as much as the life. Basso-relievo, bass-relief, or low-relievo, is when the work is raised but a little from the ground, as in medals, and the frontispieces of buildings; and particularly in the histories, festoons, foliages, and other ornaments of friezes. Demi-relievo is when one-half of the figure rises from the plan. When, in a basso-relievo, there are parts that stand clear out, detached from the rest, the work is called demi basso.

In architecture, the relievo or projection of the ornaments, ought always to be proportioned to the magnitude

tude of the building it adorns, and to the distance at which it is to be viewed.

RELIEVO, or RELIEF, in painting, is the degree of boldness with which the figures seem, at a due distance, to stand out from the ground of the painting.

RELIGION, that worship and homage which is due to God, considered as our creator, preserver, and most bountiful benefactor.

As our affections depend on our opinions of their objects, it seems to be among the first duties we owe to the Author of our being, to form the least imperfect, since we cannot form perfect, conceptions of his character and administration: for such conceptions will render our religion rational, and our dispositions refined. If our opinions are diminutive and distorted, our religion will be superstitious, and our temper abject. Thus, if we ascribe to the Deity that false majesty, which consists in the unbenevolent and sullen exercise of mere will or power, or suppose him to delight in the prostrations of servile fear, or as servile praise, he will be worshipped with mean adulation, and a profusion of compliments. If he be looked upon as a stern and implacable being, delighting in vengeance, he will be adored with pompous offerings, or whatever else may be thought proper to sooth and mollify him. But if we believe perfect goodness to be the character of the Supreme Being, and that he loves those who resemble him most, in this, the most amiable of his attributes, the worship paid him will be rational and sublime, and his worshippers will seek to please him by imitating that goodness which they adore. Indeed, wherever right conceptions of the Deity, and his providence, prevail, when he is considered as the inexhausted source of light, and love, and joy, as acting in the joint character of a father and governor, what veneration and gratitude must such conceptions, thoroughly believed, excite in the mind? how natural and delightful must it be, to one whose heart is open to the perception of truth, and of every thing fair, great, and wonderful in nature, to engage in the exercises of religion, and to contemplate and adore him, who is the first fair, first great, and first wonderful; in whom wisdom, power, and goodness dwell vitally, essentially, and act in perfect concert? what grandeur is here, to fill the most enlarged capacity; what beauty to engage the most ardent love; what a mass of wonders, in such exuberance of perfection, to astonish and delight the human mind, through an unfailling duration! When we consider the un sullied purity, and absolute perfection of the divine nature; and reflect on the imperfection and various blemishes of our own, and the ungrateful returns we have made to his goodness, we must sink, or be convinced we ought to sink, into the deepest humility and prostration of soul before him, and be conscious that it is our duty to repent of a temper and conduct so unworthy of our nature, and so unbecoming our obligations to its author; and to resolve and endeavour to act a wiser and a better part for the future. And if the Deity is considered as the father of mercies, who loves his creatures with infinite tenderness, and, in a particular manner, all good men; nay, who delights in goodness even in its most imperfect degrees; what resignation, what dependence, what generous confidence, what hope in God, and in his all-wise providence, must arise in the soul that is possessed of such amiable views of him. We must farther observe, that all those affections which regard the Deity as their immediate and primary object, are vital energies of the soul, and consequently exert themselves into act, and, like all other energies, gain strength or greater activity by that exertion: it is therefore our duty, as well as highest interest, often, at stated times, and by decent and solemn acts, to adore the great original of our existence, to express our veneration and love by a devout recognition of his perfections, and to evidence our gratitude by celebrating his goodness, and thankfully acknowledging all his benefits; by proper exercises of sorrow and humiliation to confess our ingratitude and folly, to signify our dependence on God, our confidence in his goodness; and our resignation to the disposals of his providence, and this not only in private, but in public worship, where the presence of our fellow-creatures, and the powerful contagion of the social affections, conspire

to kindle and spread the devout flame with greater warmth and energy.

Religion is divided into natural and revealed. By natural religion is meant that knowledge, veneration, and love of God, and the practice of those duties to him, our fellow-creatures, and ourselves, which are discoverable by the right exercise of our rational faculties, from considering the nature and perfections of God, and our relation to him and to one another. See ETHICS.

And by revealed religion is meant, natural religion explained, enforced, and enlarged, from the express declarations of God himself, from the mouths or pens of his prophets, &c.

Religion, in a more contracted sense, is used for that system of faith and worship, which obtains in several countries of the world; and even for the various sects into which each religion is divided.

RELIGIOUS, in popish countries, is particularly used for a person engaged, by solemn vows, to the monastic life: or a person shut up in a monastery, to lead a life of devotion and austerity, under some rule or institution.

RELIQUARY, a shrine or casket, wherein the relics of a dead saint are kept.

REMAINDER, in law, is an estate in lands, tenements, or rents, not to be enjoyed till after a term of years, or another person's decease: thus, a person grants lands or tenements to one person, for a term of years, or for life, and the remainder to another person for life, or in fee.

REMAINDER, in mathematics, is what is left after taking a lesser number out of a greater.

REMEDY, in medicine, a preparation applied either internally or externally, for the cure of a disease.

REMINISCENCE, *Reminiscencia*, that power of the human mind, whereby it recollects itself, or calls again into its remembrance such ideas or notions as it had really forgot: in which it differs from memory, which is a treasuring up of things in the mind, and keeping them there, without forgetting them.

REMISSION, in physics, the abatement of the power, or efficacy of any quality, in opposition to the increase of the same, which is called intensification.

REMISSION, in medicine, is when a distemper abates, but does not go quite off before it returns again, as is common in fevers, which do not quite intermit.

REMITTANCE, in commerce, the traffic or return of money from one place to another, by bills of exchange, orders, or the like.

This word is also used in speaking of the payment of a bill of exchange. It also signifies the fee or reward given a banker, both of his wages and the different value of the species in the places where you pay the money, and where he remits it.

REMITTER, in law. Where a person has two titles to lands, &c. and he comes to such lands by the last title, which proving defective, he shall be restored to, and adjudged in, by virtue of his former more ancient title, this is called remitter.

REMONSTRANCE, an expostulation or humble supplication, addressed to a king, or other superior, beseeching him to reflect on the inconveniences, or ill consequences of some order, edict, or the like.

REMORA, the suck-fish, in ichthyology, a singular fish which grows to about nine inches in length, and more than two in diameter in the largest part of the body, which is near the head, whence it becomes gradually smaller to the tail; the back is convex, the belly flat, and the sides are rounded by means of the structure of its head. This fish applies itself firmly to any solid body that it pleases; and is frequently found sticking to the bottom of ships, and often to large fish.

REMOUNT, in war. To remount the cavalry, is to furnish troopers or dragoons with fresh horses, instead of such as have been killed or disabled in the service.

RENAL, something belonging to the reins or kidneys. See KIDNEYS.

RENCOUNTER, in the military art, an engagement of two little bodies or parties of forces; in which sense it stands in opposition to a pitched battle.

RENCOUNTRÉ, or RECONTRÉ, in heraldry, is applied to animals when they shew their head in front,

REP

with both eyes, &c. or when the face stands right forward, as if they came to meet the person before them.

RENDERING, in sea affairs, sliding or yielding through any place, as in the several holes, or channels, of the blocks of a tackle. When all the parts yield, or draw, without interruption, they are said to render.

RENDEZVOUS, or **RENDEVOUS**, a place appointed to meet in, at a certain day and hour.

RENIFORM, something resembling the figure or shape of the kidneys. See **KIDNEY**.

RENITENCY, *renitentia*, among philosophers, that force in solid bodies, whereby they resist the impulse of other bodies, or re-act as much as they are acted on.

RENT, *reditus*, in law, a sum of money, or other consideration, issuing yearly out of lands or tenements.

RENTAL, signifies a roll in which the rents of manors are set down, in order for the lord's bailiff thereby to collect the same. It contains the lands let to each tenant, with their names, and the several rents arising.

RENTING, in the manufactories, the same with fine-drawing.

RENVERSE, in heraldry, is when any thing is set with the head downwards, or contrary to its natural way of standing. Thus, a chevron renversé, is a chevron with the point downwards. They use also the same term when a beast is laid on its back.

RENUENTES, in anatomy, a pair of muscles of the head, thus called as being antagonists to the annuents, and serving to throw the head backwards.

RENUNCIATION, *renunciatio*, the act of renouncing, abdicating, or relinquishing any right, real or pretended.

REPAIRING, or **REPARATION**, *reparatio*, the act of retrieving, mending, or establishing a building, or other work, damaged or gone to decay.

REPARTEE, or **REPARTY**, a ready smart reply, especially in matters of wit, humour, or raillery.

REPARTITION, a dividing or sharing a thing a second time.

REPEALING, in law, the revoking or annulling of a statute, or the like.

REPEAT, in music, a character shewing that what was last played or sung must be repeated, or gone over again.

REPELLANTS, in medicine, remedies which drive back a morbid humour into the mass of blood, from which it was unduly secreted.

REPERCUSSION, in mechanics. See the article **REFLECTION**.

REPERCUSSION, in music, a frequent repetition of the same sound.

REPERTORY, *Repertorium*, a place wherein things are orderly disposed, so as to be easily found when wanted. The indices of books are repertories, shewing where the matters sought for are treated of. Common-place books are also kinds of repertories.

REPETITION, in music, denotes reiterating, or playing over-again, the same part of a composition, whether it be a whole strain, part of a strain, or double strain, &c.

REPETITION, in rhetoric, a figure which gracefully and emphatically repeats either the same word, or the same sense in different words.

REPLANTING, in gardening, the act of planting a second time. See **PLANTING**.

REPLETION, in medicine, a plenitude or plethora. See **PLETHORA**.

Repletion is more dangerous than inanition. Bleeding and diet are the great resources when a person is incommoded with a repletion.

Repletion is sometimes also used where the stomach is overladen with too much eating or drinking. The physicians hold all repletion to be prejudicial, but that of bread is of all others the worst.

REPLETION, in the canon law, is where the revenue of a benefice or benefices is sufficient to fill or occupy the whole right or title of the graduate who holds them. Where there is a repletion, the party can demand no more by virtue of his degrees. In England, where benefices are not appropriated to degrees, repletion, strictly speaking, has no place.

REP

REPLEVIN, in law, a remedy granted on a distress, by which the first possessor has his goods restored to him again, on his giving security to the sheriff that he will pursue his action against the party distraining, and return the goods or cattle, if the taking them shall be adjudged lawful.

REPLEVISH, in law, signifies to admit one to main-prize upon surety.

REPLEVY, in law, is a tenant's bringing a writ of replevin, or replegiari facias, where his goods are taken by distress for rent; which must be done within five days after the distress, otherwise at the five days end, they are to be appraised and sold. 2 W. and M. c. 5.

This word is also used for bailing a person, as in the case of a homine replegiando.

REPLICATION, in logic, the assuming or using the same term twice in the same proposition.

REPORT, the relation made upon oath, by officers or persons appointed to visit, examine, or estimate the state, expences, &c. of any thing.

REPORT, in law, is a public relation of cases judiciously argued, debated, resolved, or adjudged in any of the king's courts of justice, with the causes and reasons of the same, as delivered by the judges.

REPOSE, in poetry, &c. the same with rest and pause. See **REST**, &c.

REPOSE, in painting, certain masses or large assemblages of light and shade, which being well conducted, prevent the confusion of objects and figures, by engaging and fixing the eye so as it cannot attend to the other parts of the painting for some time; and thus leading it to consider the several groups gradually, proceeding, as it were, from stage to stage.

REPOSITORY, a store-house, or place in which things are laid up, and preserved.

REPRESENTATION, in the drama, the exhibition of a theatrical piece, together with the scenes, machines, &c.

REPRESENTATIVE, one who personates or supplies the place of another, and is invested with his right and authority.

REPRIEVE, or **REPRIVE**, in law, is suspending or deferring the execution of the law upon a prisoner for a certain time; or a warrant from the king for deferring the execution of a person condemned.

REPRISALS, a right which princes claim of taking from their enemies any thing equivalent to what they unjustly detain from them.

REPRIZE, or **REPRISE**, at sea, is a merchant-ship which, after its being taken by a corsair, privateer, or other enemy, is retaken by the opposite party.

If a vessel, thus retaken, has been twenty-four hours in possession of the enemy, she is deemed a legal prize; but if it be retaken within that time, she is to be restored to the proprietor, with every thing therein, upon his allowing one third to the vessel who made the reprize. Also, if the reprize has been abandoned by the enemy, either in a tempest, or from any other cause, before she has been taken into any port, she is to be restored to the proprietor.

REPRIZES, in law, are deductions or payments annually made out of a manor or lands; as rent-charges, pensions, annuities, &c.

REPROBATION, in theology, a decree by which God is supposed either from all eternity, or from the creation of the world, to consign over to eternal misery the greatest part of mankind, and to save none of the human race except those whom he made the heirs of glory by election.

Casuits distinguish two kinds of reprobation, positive and negative. Positive reprobation, is that by which God is supposed to create men with a positive and absolute resolution to damn them eternally: and negative reprobation, is that whereby God, though he creates all men with a sincere desire to save them, and furnishes them with all the necessary means of salvation, so that all may be saved that will; yet sees there are several who will not do it, with the aids he shall afford them, and sees, at the same time, they would do it with certain other aids, which he sees, but will not give them.

RE-

REPRODUCTION, the act whereby a thing is produced anew, or grows a second time.

REPTILES, in natural history, a kind of animals denominated from their creeping or advancing on the belly. Or reptiles are a genus of animals and insects, which, instead of feet, rest on one part of the body, while they advance forward with the rest.

Such are earthworms, snakes, caterpillars, &c. Indeed, most of the class of reptiles have feet; only those very small, and the legs remarkably short in proportion to the bulk of the body.

Naturalists observe a world of artful contrivance for the motion of reptiles. Thus, particularly in the earthworm, Dr. Willis tells us, the whole body is only a chain of annular muscles; or, as Mr. Derham says, it is only one continued spiral muscle, the orbicular fibres whereof being contracted, render each ring narrower and longer than before; by which means it is enabled, like the worm of an auger, to bore its passage into the earth. Its reptile motion might also be explained by a wire wound on a cylinder, which when slipped off, and one end extended and held fast, will bring the other near to it. So the earth-worm having shot out or extended his body (which is with a wreathing) it takes hold by these small feet it hath, and so contracts the hinder part of its body. Dr. Tyson adds, that when the fore-part of the body is stretched out, and applied to a plane at a distance, the hind part relaxing and shortening is easily drawn towards it as a center.

Its feet are disposed in a quadruple row the whole length of the worm, with which, as with so many hooks, it fastens down sometimes this and sometimes that part of the body to the plane, and at the same time stretches out or drags after it another.

The creeping of serpents is effected after a somewhat different manner; there being a difference in their structure, in that these last have a compages of bones articulated together.

The body here is not drawn together, but as it were complicated; part of it being applied on the rough ground and the rest ejaculated and shot from it, which, being set on the ground in its turn, brings the other after it. The spine of the back variously wreathed has the same effect in leaping, as the joints in the feet of other animals; they make their leaps by means of muscles, and extend the plicæ or folds.

REPTILE is also used, by some botanical writers, to signify plants which creep upon the earth, unless sustained by some other plant, prop, &c. as cucumbers, melons, the vine, &c.

REPUBLIC, *Respublica*, commonwealth, a popular state or government; or a nation where the people have the government in their own hands.

REPUBLIC of Letters, a phrase used collectively of the whole body of the people of study and learning.

REPUDIATION, *Repudium*, in the civil law, the act of divorcing. See **DIVORCE**.

REPULSION, *Repulsio*, in physics, that property in bodies, whereby, if they are placed just beyond the sphere of each other's attraction of cohesion, they mutually fly from each other.

REQUIEM, in the Romish church, a mass sung for the rest of the soul of a person deceased.

RESCEIT, *Receptio*, in law, an admission or receiving of a third person to plead his right in a cause formerly commenced between the other two.

RESCISSION, *Rescissio*, in the civil law, an action intended for the annulling, or setting aside, any contract, deed, &c.

RESCRIPT, *Rescriptum*, an answer delivered by an emperor, or a pope, when consulted by particular persons, on some difficult question, or point of law; to serve as a decision thereof.

RESEARCH, a scrutiny, or diligent enquiry into any thing.

RESEARCH, in music, is a kind of prelude or voluntary played on the organ, &c. wherein the performer seems to search or look out for the strains and touches of harmony, which he is to use in the regular piece to be played afterwards.

RESEARCHING, in sculpture, the repairing of a cast figure, &c. with proper tools; or the finishing it with art and exactness, so as the minutest parts may be well defined.

RESERVATION, in law, an action or clause whereby something is reserved, or secured to one's self.

Mental RESERVATION, a proposition, which strictly taken, and according to the natural import of the terms, is false; but, if qualified by something concealed in the mind, becomes true.

RESERVE, in law, the same with reservation. See the article **RESERVATION**.

Body of RESERVE, or *Corps de RESERVE*, in military affairs, the third or last line of an army, drawn up for battle; so called, because they are reserved to sustain the rest, as occasion requires; and not to engage, but in case of necessity.

RESERVOIR, a place where water is collected and reserved, in order to be conveyed to distant places through pipes, or supply a fountain, or jet d'eau.

RESET, in law, the receiving or harbouring an outlawed person.

RESIDENCE, in the canon and common law, the abode of a person, or incumbent, upon his benefice; and his assiduity in attending on the same.

RESIDENT, a public minister, who manages the affairs of a kingdom or state, at a foreign court.

RESIDENTIARY, *Residentarius*, a canon installed into the privileges and profits of residence.

RESIDUAL FIGURE, in geometry, the figure remaining, after subtracting a lesser from a greater.

RESIDUAL ROOT, in algebra, a root composed of two parts or members, connected together by the sign—.

Thus $x - y$ is a residual root, so called, because its value is no more than the difference between its parts x and y .

RESIDUE, *Residuum*, the remainder or balance of an account, debt, or obligation.

RESIGNATION, in the canon law, the surrendering a benefice into the hands of the collator, or bishop.

RESIGNEE, in law, the person to whom a thing is resigned.

RESIN, in natural history, a viscid juice oozing either spontaneously, or by incision, from several trees, as the pine, fir, &c.

For the difference between resins and gums, see the article **GUM**.

Natural resins are either solid or fluid. Of the solid resins, some are used more frequently in medicine, as storax, benzoine, mastich, olibanum, elemi, lac, dragon's-blood, and camphor; and others more rarely, as anime, copal, caranna, tachamahaca, laudanum, sandarach, &c. See **STORAX**, **BENZOINE**, &c.

The liquid resins, used in medicine, are less numerous, viz. balsam of Gilead, of Peru, of Tolu, of capivi, turpentine, liquid amber, and liquid storax. See the articles **BALSAM**, **TURPENTINE**, &c. &c.

RESISTENCE, or **RESISTING Force**, in philosophy, any power which acts opposite to another, so as to destroy or diminish its effect.

There are various kinds of resistance, arising from the various natures and properties of the resisting bodies, and governed by various laws, as the resistance of solids, the resistance of fluids, resistance of the air, &c.

Theory of the RESISTENCE of the Fibres of solid Bodies.—To conceive the idea of this resistance, or renitency, of the parts, suppose a cylindrical body suspended vertically by one end. — Here, all its parts, being heavy, draw downwards, and tend to separate the two contiguous planes, where the body is the weakest: but all the planes resist this separation by the force wherewith they cohere, or are bound together: here, then, are two opposite powers; viz. the weight of the cylinder which tends to break it, and the force of cohesion of the parts which resists the fracture.

If the base of the cylinder be increased, without increasing its length; it is evident the resistance will be increased in the same ratio as the strength of the base: but the weight also increases in the same ratio; whence it is evident that all cylinders of the same matter and length, whatever

whatever their bases be, have an equal resistance, when vertically suspended.

If the length of the cylinder be increased without increasing the base, its weight is increased without increasing its resistance; consequently the lengthening it weakens it. To find the greatest length a cylinder of any matter may have without breaking, there needs nothing but to take any cylinder of the same matter, and fasten it to the greatest weight it will sustain before it breaks; and then see how much it must be lengthened by the addition of its weight, till it equals its former weight with the addition of a foreign weight. By this means Galileo found a copper-wire, and of consequence any other cylinder of copper, might be extended to 4801 braccio's, or fathoms of six feet each.

If one end of the cylinder were fixed horizontally into a wall, and the rest suspended thence, its weight, and resistance, would then act in a different manner; and, if it broke by the action of its weight, the rupture would be at the end fixed into the wall. A circle or plane contiguous to the wall, and parallel to the base, and consequently vertical, would be detached from the contiguous circle within the plane of the wall, and would descend. All the motion is performed on the lowest extremity of the diameter, which remains immoveable, while the upper extremity describes a quadrant of a circle, and till the circle which before was vertical becomes horizontal; i. e. till the cylinder be entirely broken.

In this fracture of the cylinder it is visible two forces have acted, and the one has overcome the other: the weight of the cylinder, which arose from its whole mass, has overcome the resistance which arose from the largeness of the base; and as the centers of gravity are points wherein all the forces arising from the weights of the several parts of the same bodies are conceived to be united, one may conceive the weight of the whole cylinder applied in the center of gravity of its mass; i. e. in a point in the middle of its axis; and the resistance of the cylinder applied in the center of gravity of its base; i. e. in the center of the base: it being the base which resists the fracture.

Hence it follows, that the force wherewith a cylinder or any other solid body having one end thereof fixed horizontally into a wall, and the rest suspended thence, endeavours to break off at the wall, will be as the whole weight of the body drawn into the distance of its center of gravity from the wall directly, and the strength of the base of the solid next the wall inversely.

When the cylinder breaks by its own weight, all the motion is on an immoveable extremity of a diameter of the base.—This extremity, therefore, is the fixed point of a lever, whose two arms are the radius of the base, and half the axis: and, of consequence, the two opposite forces do not only act of themselves, and by their absolute force, but also by the relative force they derive from their distance with regard to the fixed point of the lever.

Hence it evidently follows, that a cylinder, e. gr. of copper, which, vertically suspended, will not break by its own weight, if less than 480 fathom long, will break with a less length in a horizontal situation; in regard the length in this latter case contributes two ways to the fracture; both as it makes it of such a weight, and as it is an arm of a lever to which the weight is applied.—Hence, also, the smaller the base is, the less length or weight will suffice to break it; both because the resistance is really less, and because it acts by a less arm of a lever.

If two cylinders of the same matter, having their bases and lengths in the same proportion, be suspended horizontally; it is evident that the greater has more weight than the lesser, both on account of its length, and of its base. But it has less resistance on account of its length, considered as a longer arm of a lever, and has only more resistance on account of its base.—Therefore it exceeds the lesser in its bulk and weight, more than in resistance; and consequently must break more easily.

Hence we see why, upon making models and machines in small, people are apt to be mistaken as to the resistance and strength of certain horizontal pieces, when they come to execute their designs in large; by ob-

serving the same proportion as in the small.—Galileo's doctrine of resistance therefore is no idle speculation, but becomes applicable in architecture and other arts.

The weight required to break a body placed horizontally being always less than that required to break it in a vertical situation; and this weight being to be greater or less according to the ratio of the two arms of the lever; the whole theory is always reducible to this, viz. to find what part of the absolute weight the relative weight is to be, supposing the figure of the body known, which indeed is necessary, because it is the figure that determines the two centers of gravity, or the two arms of the lever.—For if the body, e. g. were a cone, its center of gravity would not be in the middle of its axis, as in the cylinder; and if it were a semiparabolical solid, neither its center of gravity would be in the middle of its length or axis, nor the center of gravity of its base in the middle of the axis of its base. But still, wheresoever these centers fall in the several figures, it is these that regulate the two arms of the lever.

It may be observed here, that if the base, whereby the body is fastened into the wall, be not circular, but, e. g. parabolical, and the vertex of the parabola a-top, the motion of the fracture will not be on an immoveable point, but on a whole immoveable line, which may be called the axis of equilibrium; and it is with regard to this, that the distance of the centers of gravity are to be determined.

Now, a body, horizontally suspended, being supposed such, as that the smallest addition of weight would break it; there is an equilibrium between its positive and relative weight; and, of consequence, their two opposite powers are to each other reciprocally as the arms of the lever to which they are applied. On the other hand, the resistance of a body is always equal to the greatest weight which it will sustain in a vertical situation without breaking, i. e. is equal to its absolute weight. Therefore, substituting the absolute weight for the resistance, it appears that the absolute weight of a body, suspended horizontally, is to its relative weight, as the distance of its center of gravity of its base from the same axis.

The discovery of this important truth, at least of an equivalent hereto, and to which this is reducible, we owe to Galileo. From this fundamental proportion are easily deduced several consequences. As for instance, that if the distance of the center of gravity of the base from the axis of equilibrium, be half the distance of the center of gravity of the body; the relative weight will only be half the absolute weight; and, that a cylinder of copper horizontally suspended, whose length is double the diameter, will break, provided it weigh half what a cylinder of the same base, 4801 fathoms long, weighs. On this system of resistance of Galileo, M. Mariotte made a very subtle remark, which gave birth to a new system. Galileo supposes that, where the body breaks, all the fibres break at once; so that the body always resists with its whole absolute force; i. e. with the whole force all its fibres have, in the place where it is broke. But, M. Mariotte finding that all bodies, even glass itself, bend before they break, shews that fibres are to be considered as so many little bent springs, which never exert their own force till stretched to a certain point, and never break till entirely unbent. Hence those nearest the axis of equilibrium, which is an immoveable line, are stretched less than those farther off, and of consequence employ a less part of their force.

This consideration only takes place in the horizontal situation of the body: in the vertical, the fibres of the base all break at once; so that the absolute weight of the body must exceed the united resistance of all its fibres: a greater weight is therefore required here, than in the horizontal situation; i. e. a greater weight is required to overcome their united resistance, than to overcome their several resistances one after another. The difference between the two situations arises hence, that in the horizontal there is an immoveable point or line, a center of motion which is not in the vertical.

M. Varignon has improved on the system of M. Mariotte, and shewn that to Galileo's system it adds the consideration of the center of percussion. The comparison

tion of the centers of gravity with the centers of percussion afford a fine view, and set the whole doctrine in the most agreeable light.

In each system, the base whereby the body breaks, moves on the axis of equilibrium, which is an immoveable line in the same base; but, in the second, the fibres of this base are continually stretching more and more, and that in the same ratio, as they recede farther and farther from the axis of equilibrium, and, of consequence, are still exerting a greater and greater part of their whole force.

These unequal extensions, like all other forces, must have some common center where they all meet, and with regard to which they make efforts on each side: and as they are precisely in the same proportion as the velocities which the several points of a rod moved circularly would have to one another; the center of extension of the base, whereby the body breaks, or tends to break, must be the same with its center of percussion. Galileo's hypothesis, where fibres stretch equally, and break all at once, corresponds to the case of a rod moving parallel to itself; where the center of extension or percussion does not appear, as being confounded with the center of gravity.

The base of fraction being a surface whose particular nature determines its center of percussion, it is necessary to be first known to find on what point of the vertical axis of that base it is placed, and how far it is from the axis of equilibrium—Indeed, we know in the general, that it always acts with so much more advantage as it is farther from it, in regard it acts by a longer arm of a lever; and of consequence it is the unequal resistance of the fibres in M. Mariotte's hypothesis, which produces the center of percussion; but this unequal resistance is greater or less according as the center of percussion is placed more or less high on the vertical axis of the base, in the different surfaces of the base of the fracture.

To express this unequal resistance, accompanied with all the variations it is capable of, regard must be had to the ratio between the distance of the center of percussion from the axis of equilibrium, and the length of the vertical axis of the base—In which ratio, the first term, or the numerator, is always less than the second or the denominator: so that the ratio is always a fraction less than unity; and the unequal resistance of the fibres in M. Mariotte's hypothesis is so much the greater, or which amounts to the same, approaches so much nearer to the equal resistance in Galileo's hypothesis, as the two terms of the ratio are nearer to an equality.

Hence it follows, that the resistance of bodies, in M. Mariotte's system, is to that in Galileo's, as the least of the terms in the ratio is to the greatest—Hence, also, the resistance being less than what Galileo imagined, the relative weight must also be less; so that the proportion already mentioned between the absolute and relative weight cannot subsist in the new system, without an augmentation of the relative weight, or a diminution of the absolute weight: which diminution is had by multiplying the weight by the ratio, which is always less than unity. This done, we find that the absolute weight, multiplied by the ratio, is to the relative weight, as the distance of the center of gravity of the body from the axis of equilibrium is to the distance of the center of gravity of the base of fracture from the same axis. Which is precisely the same thing with the general formula given by M. Varignon, for the system of M. Mariotte. In effect, after conceiving the relative weight of a body, and its resistance equal to its absolute weight, as two contrary powers applied to the two arms of a lever, in the hypothesis of Galileo; there needs nothing to convert it into that of M. Mariotte, but to imagine that the resistance, or the absolute weight, is become less, every thing else remaining the same.

We have here only considered bodies as to be broke by their own weight—It will amount to the same, if we suppose them void of weight themselves, and to be broken by a weight applied to their extremities: only it is to be observed, that a foreign weight acts by an arm of a lever equal to the whole length of a body; whereas their own weight, being all united in the center of gravity,

is only the distance of that center from the axis of equilibrium.

One of the most curious, and perhaps the most useful questions in this research, is to find what figure a body must have, that its resistance may be equal in all its parts; whether it be conceived as loaded with a foreign weight, or as only sustaining its own weight—We shall, here, only consider the latter case, from which the former will be easily determined. For a body, then, suspended horizontally, to resist equally in all its parts; it is necessary, some part of it being conceived as cut off in a plane parallel to the base of fracture of the body, the weight of the part retrenched be to its resistance, in the same ratio, as the weight of the whole to its resistance; these four powers acting by arms of levers peculiar to themselves—Now the weight of any body, thus conceived, is its whole weight multiplied by the distance of the center of gravity of the body from the axis of equilibrium; and the resistance is the plane of the base of fracture multiplied by the distance of the center of gravity of the base from the same axis: consequently these four quantities are to be proportional in the whole, and in each part of a solid of equal resistance.

From this proportion M. Varignon easily deduces two solids, which shall resist equally in all their parts; Galileo had found one before: that discovered by M. Varignon is in form of a trumpet, and is to be fixed into the wall at its greater end; so that its bigness and weight is always diminished in proportion as its length, or the arm of the lever whereby its weight act increases. It is added (which seems very remarkable) that, howsoever different the two systems may be, the solids of equal resistance are the same in both.

RESISTENCE of fluids, in hydrostatics, is the force wherewith bodies, moving in fluid mediums, are impeded and retarded in their motion.

Laws of the RESISTENCE of fluid Mediums.—The resistance a body meets with in moving through a fluid, is of three kinds; the first arises from the friction of the body against the particles of the fluid; the second from their cohesion or tenacity among themselves; the third, from their inactivity, or the tendency they have, in common with other bodies, to keep the places they possess.

The first, viz. that which arises from the friction of the body against the particles of the fluid, is very inconsiderable; for whatever the weight is, which presses the particles of a fluid together, the freedom, with which a body moves through it, is not sensibly diminished thereby.

The second, or that which arises from the tenacity of the particles of the fluid, is as the time the body continues passing in it: thus, suppose a body continues to move within a fluid for the space of one hour; if its motion be very quick during that time, it then moves a great way in that fluid, and consequently meets with a great deal of the fluid to resist it; but is resisted the less in each part thereof, in proportion to the stay it makes there: whereas, if its motion be slow, it then moves but a little way in that time, but is resisted so much the longer in each part thereof. So that, whether the body moves fast or slow, the resistance it suffers is the same; and depends, therefore, on nothing but the time we suppose it to continue moving within the fluid. This species of resistance is also very small, except in glutinous and viscid fluids, whose parts are not easily separated.

The third species is the principal resistance that fluids give to bodies, and arises from their inactivity, or the tendency the particles, of which they consist, have to continue at rest. The quantity of this resistance depends on the velocity the body moves with, on a double account: for, in the first place, the number of particles put into motion by the moving body in any determinate space of time, is proportionable to the velocity wherewith the body moves; and, in the next place, the velocity with which each of them is moved, is also proportionable to the velocity of the body; this species, therefore, of resistance, is in a duplicate proportion, or as the square of the velocity, with which the body moves through the fluid.

2. Farther, the resistance a body moving in a fluid meets with from thence, may be considered with regard to the fluid; and then it will be found to be more or less, according to the density of the fluid. For by how much denser the fluid is, so much the greater number of particles are to be put into motion by the body, in order to make its way through it.

3. The next thing to be considered is, the effects of the resistance of fluids upon bodies moving in them; that is, the retardation, which they cause in the motion of a body by their resistance, or the quantity of motion they destroy.

And this, in similar bodies of equal magnitudes, is inversely as their densities, or the quantity of matter they contain; for by how much the greater the quantity of matter in any body is, so much the more easily does it overcome the resistance it meets with from the fluid. Thus, we see the resistance of the air has a much less effect in destroying the motion of an heavy body, than of a light one which has the same dimensions.

4. In similar bodies of equal densities, but different magnitudes, the retardation is inversely as their homologous sides. For the resistance bodies meet with in a fluid, is inversely as the quantities of matter they contain (by the last) that is, inversely as the cubes of their homologous sides; and it is also directly as their surfaces, because it is by them that they move the fluid out of its place; that is, directly as the squares of their homologous sides; consequently, the retardation is inversely as their homologous sides.

RESISTENCE of the Air to the motion of projectiles.—In Phil. Trans. N^o. 186. there is the measure of this given very largely and accurately by Dr. Wallis: He lays down at first this lemma, that the resistance of bodies is proportional to their celerity; and then branches it out into all the particular varieties that can well be imagined, and at last, comparing different mediums one with another, he concludes their different resistances to be as their specific gravities, obstructed from the viscosity of the particles of some fluids: and also that the specifically heavier project once in motion (being equally swift with another that is lighter, &c.) will move through the same medium more strongly in proportion to its greater intensive or specific gravity.

In the Acta Eruditorum Lipsiæ for July 1684, Mr. G. G. Leibnitz proposes some new demonstrations about the resistances of solid bodies, which are very geometrical and curious.

And in the Leipzig Acts for January 1689, he reduces his thoughts on this subject into a dissertation, intitled, A discourse concerning the resistance of mediums, and the motion of projects in resisting mediums.

As to the geometrical considerations of the resistance of bodies of different figures in one and the same medium, Mr. James Bernoulli, in the Acta Lipsiæ for May 1693, gives these rules:

1. If an isosceles triangle be moved in the fluid according to the direction of a line which is normal to its base; first with the vertex foremost, and then with its base; the resistances will be as the legs, and as the square of the base, and as the sum of the legs.

2. The resistance of a square moved according to the direction of its side, and of its diagonal, is as the diagonal to the side.

3. The resistance of a circular segment (less than a semi-circle) carried in a direction perpendicular to its basis, when it goes with the base foremost, and when with its vertex foremost (the same direction and celerity continuing, which is all along supposed) is as the square of the diameter to the same less one-third of the square of the base of the segment.

Cor. Hence the resistances of a semi-circle when its base, and when its vertex goes foremost, are to one another in a sesquialteral ratio.

4. A parabola moving in the direction of its axis, with its basis, and then its vertex foremost, has its resistances, as the tangent to an arch of a circle, whose diameter is equal to the parameter, and the tangent equal to half the basis of the parabola.

5. The resistances of an hyperbola, or the semi-ellipsis, when the base and when the vertex goes foremost,

may be thus computed: let it be, as the sum, or difference, of the tranverse axis, and latus rectum, is to the tranverse axis: so is the square of the latus rectum to the square of the diameter of a certain circle; in which circle apply a tangent equal to half the basis of the hyperbola or ellipsis. Then say again, as the sum, or difference, of the axis and parameter is to the parameter; so is the aforesaid tangent to another right line. And further, as the sum, or difference, of the axis and parameter is to the axis: so is the circular arch, corresponding to the aforesaid tangent, to another arch. This done, the resistances will be as the tangent to the sum, or difference, of the right line thus found, and that arch last mentioned.

6. In general, the resistances of any figure whatsoever going now with its base foremost, and then with its vertex, are as the figures of the basis to the sum of all the cubes of the elementa of the basis divided by the squares of the elementa of the curve line.

All which rules, he thinks, may be of use in the fabric or construction of ships, and in perfecting the art of navigation universally. As also for determining the figures of the bobs of pendulums for clocks.

Solid of least RESISTENCE, a solid that, in passing thro' a resisting medium, has the least resistance of any, containing the same quantity of matter and surface. See **SOLID of least Resistance**.

RESOLUTION, in chemistry, &c. the reduction of a mixed body into its component parts, or first principles, by a proper analysis.

RESOLUTION, in medicine, that coction or alteration of the crude peccant matter of any disease, either by the natural strength of the patient, or of its own accord, or by the application of remedies, whereby its bulk, figure, cohesion, &c. are so far changed, as that it ceases to be morbid, and becomes laudable. This Boerhaave observes, is of all others the most perfect cure, where it is effected without any evacuation, as supposing the matter favourable, the constitution excellent, and the medicines good.

RESOLUTION, in music, is when a canon or perpetual figure is not wrote on a line, or in one part; but all the voices that are to follow the guide or first voice, are wrote separately either in score, that is in separate lines, or in separate parts, with the pauses each is to observe, and in the proper tone to each.

RESOLVENTS, *Resolventia*, in medicine, remedies proper to resolve and dissipate tumours and gatherings; to soften indurations, and, by their tenuity and warmth, evacuate redundant or peccant humours through the pores. Under this class come various unguents, emplasters, &c.

RESONANCE, **RESONDING**, in music, &c. a sound returned by the air, inclosed in the bodies of stringed musical instruments, as lutes, &c. or even in the bodies of wind instruments, as flutes, &c. See **SOUND** and **MUSIC**.

Elliptic and parabolic vaults resound strongly, that is, they will reflect or return a sound. The mouth, and the parts thereof, as the palate, tongue, teeth, nose, and lips, M. Dodart observes, contribute nothing to the tone of the voice, but their effect is very great as to the resonance: of this we have a very sensible instance in that vulgar instrument called a Jews-harp, or trompe de Bearn; for if you hold it in your hand, and strike the tongue or spring thereof, which is the method practised to sound this instrument, it yields scarce any noise; but holding the body of it between the teeth, and striking it as before, it makes a musical buzz, which is heard at a good distance, and especially the lower notes.

RESPIRATION, *respiratio*, the act of respiring, or breathing the air. What respiration is, and why it is uninterruptedly carried on without the concurrence of the mind, will appear from the following considerations of Boerhaave.

The lungs suspended in the air, which every where acts upon them, and equally presses them always, collapse, contract themselves into a smaller space, and become much less than when they remain in the intire thorax. This is principally performed by the contractile force of the muscular fibres, which connect the squamous segments of the bronchia. If the lungs thus contracted,

tracted, are filled with air, forcibly blown through the glottis, they are so distended as, in bulk, not only to equal that which they had in the intire thorax, but even to exceed it; all which is sufficiently certain from experiments. The same thing happens if, when an access for the air through the glottis is left to the lungs, the air externally acting on the lungs, is either removed, or its pressure diminished. Hence it is obvious, that the lungs, by their proper force, have always a tendency to become less in all their parts than they are when placed in the entire thorax. For this reason, it is certain that they are in a continual state of distraction so long as a person is alive, so that they must collapse, and be diminished, whilst the whole of the animal remains in a vacuum, obtained by an exhaustion of the air in an air-pump. For there is nothing similar to a circumambient air between the external membrane of the lungs, and all the internal surface of the pleura in a sound person; nothing therefore externally compresses the lungs, except the diaphragm. There is, however, always an internal air contained in them, and freely conveyed to them through the glottis. Hence the lungs are always somewhat more distended by the internal, than they are compressed by the external air, the access of which is hindered by the diaphragm, which is so connected with the ribs and vertebræ, that the air cannot enter the thorax in such a manner as would be requisite for an equilibrium.

Since, therefore, in inspiration, a greater quantity of air enters the lungs through the glottis, it will extend the lungs more, and overcome their natural force, so that in this action the lungs are passive; but how far they are active is only to be discovered from certain phenomena. In vital inspiration, then, especially considered in a sleeping person, first the ribs, particularly the nine superior ones, articulated at the vertebræ, and by cartilages joined to the sternum, with their arched part, rise to the clavicles, so that this motion is principally observed in the middle of the arch, whilst three, or perhaps four, inferior ribs are turned downwards, backwards, and obliquely outwards, but in such a manner that the seventh, eighth, ninth, and tenth ribs are by their cartilaginous segments, as it were, drawn inwards. Secondly, the whole abdomen, to the very end of inspiration, is gradually rendered more tumid and pressed downwards. Thirdly, at the same time the cavity of the thorax is enlarged, as is obvious from repeated experiments.

Whilst the parts remain in this situation, the air acts upon the lungs with a force equal to that with which the thorax resists, so that the lungs will remain in a state of rest. Hence less blood will pass through them, and a smaller quantity of it will be forced into the left ventricle of the heart, and consequently less blood will be conveyed to the cerebellum and its nerves. The arterial blood will also act less upon the intercostal muscles and diaphragm, so that the causes dilating the thorax are weakened. Hence the elasticity of the cartilaginous segments again depresses the ribs, in which work they are also assisted by the muscular fibres arising from the side of the sternum within the thorax, and inserted into the bony extremities, and cartilages of the true ribs. At the same time the distracted fibres of the peritonæum and abdominal muscles restore themselves. Hence the compressed viscera thrust the relaxed diaphragm upwards into the thorax, which is by this means contracted, and the air expelled from the lungs. By this means, expiration and the action already mentioned, are performed. But in a particular manner by these two actions the blood is not only carried through the lungs, but its motion accelerated. See CIRCULATION, &c.

Physicians are not agreed about the use and effects of respiration; some think that the air is insinuated into the vessels of the lungs, to give a greater fluidity and motion to the blood; others, that it conveys very subtil nitrous corpuscles thereunto, which gives it the red colour; others again, believe the air serves to condense the blood, which has been heated by circulation. This is certain, that the air entering into the lungs, and all the small ramifications which surround its vessels, is broke, comminuted, and rendered more fluid, and that it is deprived

of a ferosity, which proceeds from the lungs by perspiration, in the form of a vapour that is visible in cold weather. It may be added, that the voice, laughter, coughing, sneezing, yawning, and sucking, depend upon respiration. Boerhaave takes the principal uses of respiration to be the further preparation of the chyle, its more accurate mixture with the blood, and its conversion into a nutritious juice, proper to repair the decays of the body. Other authors take a great use of respiration to be, by the neighbourhood of the cold nitrous air, to cool the blood coming reeking hot out of the right ventricle of the heart through the lungs, and to act as a refrigeratory; others assert one grand use of respiration to be the throwing off the fuliginous vapours of the blood, along with the expelled air; and for inspiration they assert, that it conveys a nitro-aerial ferment to the blood, to which the animal spirits, and all muscular motion, are owing. But Dr. Thurston rejects all these, as being the principal uses of respiration, and from the experiments of Dr. Croon, Dr. Hook, and others, made before the Royal Society, he shews the principal use of respiration to be that of moving, or passing the blood from the right to the left ventricle of the heart, and so to effect circulation; whence it is, that persons hanged, drowned, or strangled, so suddenly die, viz. because the circulation of the blood is stopped, and for the same reason it is, that animals die so speedily in the air-pump. This use of respiration Dr. Drake not only confirms, but carries farther, making it the true cause of the diastole of the heart, which neither Borelli, Dr. Lower, nor Mr. Cowper, had well accounted for. See DIASTOLE and SYSTOLE.

From experiments made upon dogs, and other animals, Dr. Hales shews, that without respiration, the blood would soon turn putrid and pestilential; and indeed the only animal exempted from the necessity of respiration is a foetus. See FOETUS.

With regard to the force of respiration, the last mentioned author observes, that though a man by a peculiar action of his mouth and tongue, may suck mercury twenty-two inches, and some men twenty-seven or twenty-eight, high, yet he found from experience, that by the bare inspiring action of the diaphragm and dilating thorax, he himself could scarcely raise the mercury two inches, at which time the diaphragm must act with a force equal to the weight of a cylinder of mercury, whose base is commensurate to the area of the diaphragm, and its height two inches, whereby the diaphragm must at the same time sustain a weight equal to many pounds; neither are its counteracting muscles, those of the abdomen, able to exert a greater force.

With regard to the quantity of moisture carried off by respiration, the doctor, from an experiment on wood-ashes, estimates that quantity to be equal to seventeen grains in fifty expirations, whence there will proportionably be four hundred and eight grains evaporated, or breathed off, in twelve hundred expirations, being the number in an hour, and thence in twenty-four hours 9792 grains, or 1.39 pounds, which supposing the surface of the lungs to be 41635 square inches, then the quantity evaporated from that inward surface will be $\frac{1}{15}$ th part of an inch depth.

From the violent and fatal effects of noxious vapours on the respiration and life of animals, the doctor shews how the respiration is proportionably incommoded when the air is loaded with lesser degrees of vapours, which vapours do in some measure clog and lower the air's elasticity, which it best regains by having these vapours dispelled by the ventilating motion of the free open air, that is best rendered wholesome by the agitation of winds; thus what we call a close warm air, such as has been long confined in a room, without having the vapours in it carried off by communicating with the open air, is apt to give us more or less uneasiness in proportion to the quantity of vapours which are floating in it. And thus, many of those who have weak lungs, but can breathe very well in the fresh country air, are greatly incommoded in their breathing, when they come into large cities, where the air is full of fuliginous vapours; and even the most robust and healthy, in changing from a city to a country air, find an exhilarating pleasure, arising from a more free and kindly inspiration, whereby the lungs being less loaded

loaded with condensing air and vapours, and thereby the vesicles more dilated with a clearer and more elastic air, a freer course is thereby given to the blood, and probably, a purer air mixed with it. See the article AIR.

RESPITE, in law, &c. signifies a delay, forbearance, or prolongation, of time, granted any one, for the payment of a debt, or the like.

RESPONDENT SUPERIOR, in law, is a superior's answering for the insufficiency of an inferior. Thus, if the sheriffs of London are insufficient, the lord-mayor and commonalty must answer for them, as the sheriffs superior.

RESPONDENT, in the schools, one who maintains a thesis, in any art or science; who is thus called, from his being to answer all the objections proposed by the opponent.

RESPONDENT, in law, a person who undertakes to answer for another; and also, one who binds himself as a security for another person's good behaviour.

RESPONSALIS, in law, is a person who answers for another, in court, at a day assigned.

RESPONSARY SONG, an anthem, in which the choiristers sing by turns.

RESSAULT, in architecture, is the effect of a body which either projects or sinks back; that is, stands more out or in, than another, so as to be out of the line or level with it.

REST, *Quies*, the continuance of a body in the same place, or its continual application or contiguity to the same parts of the ambient or contiguous bodies; and, therefore, is opposed to motion. See the article MOTION.

Sir Isaac Newton defines true or absolute rest, to be the continuance of a body in the same part of absolute space; and relative rest to be the continuance of a body in the same part of relative space.

It is one of the laws of nature, that matter is indifferent to motion or rest, as has been shewn under the article INERTIA.

REST, considered in a physical view, is only salutary, in so far as it is duly proportioned to the exercise; for a sedentary idle life brings on many indispositions.

REST, in poetry, is a short pause of the voice in reading, being the same with the *cæsura*, which, in Alexandrine verses, falls on the sixth syllable; but in verses of ten or eleven syllables, on the fourth.

REST, in music, the same with pause. See the article PAUSE.

RESTAURATION, in sculpture, is the repairing a mutilated statue, &c.

Many of the antique statues have undergone a restoration; as the Wrestlers, in the gallery of the great duke of Florence; the Farnese Hercules; the Faunus in the Villa Borghese, at Rome; and the Venus of Arles, in the gallery at Versailles; but these restorations have all been made by the ablest sculptors.

RESTINCTION, in chemistry, is the quenching a metal or mineral in some liquor, in order either to correct or exhale it, by giving it some new power or quality.

RESTITUTION, in physics, is restoring an elastic body, forcibly bent, to its natural state. See the article ELASTICITY.

RESTITUTION, in a moral and legal sense, is restoring a person to his right; or returning something unjustly taken or detained from him.

RESTITUTION of Medals, or RESTITUTED MEDALS, is a term used by antiquaries, for such medals as were struck by the emperors, to retrieve the memory of their predecessors.

RESTIVE, or RESTY, in the manege, a stubborn, unruly, ill-broken horse, that stops, or runs back, instead of advancing forward.

RESTORATIVE, in medicine, a remedy proper for restoring and retrieving the strength and vigour both of the body and animal spirits.

RESTRICTION, among logicians, is limiting a term, so as to make it signify less than it usually does.

RESTRINGENT, in medicine, the same with astringent. See ASTRINGENT.

RESULT, what is gathered from a conference, inquiry, meditation, or the like; or the conclusion and effect thereof.

RESURRECTION, in theology, rising again from the dead; or a person's returning to a second life, with new bodily organs, adapted to the state of its new existence.

One of the greatest arguments for the truth of Christianity is drawn from the resurrection of our Saviour; the circumstances of which are handed down to us in so plain and distinct a manner, by the Evangelists, as make the evidence of this important truth amount to a demonstration.

Christians generally believe, that at the day of judgment, the very identical body they have now, with the same flesh, blood, and bones, will be raised from the dead. But, in opposition to this opinion, many texts of scripture have been urged, particularly the account given of this important event by St. Paul; besides several philosophical objections.

RESUSCITATION, the same with resurrection and revivification. See REVIVIFICATION.

RETAINER, in law, a servant who does not continually dwell in the house of his master, but only attends upon special occasions.

RETAINING FEE, the first fee given to a serjeant, or counsellor at law, in order to make him sure, and prevent his pleading on the contrary side.

RETALIATION, among civilians, the act of returning like for like. See the article TALIONIS LEX.

RETARDATION, in physics, the act of diminishing the velocity of a moving body.

If bodies of equal bulk, but of different densities, be moved through the same resisting medium, with equal velocity, the medium will act equally on each, so that they will have equal resistances, but their motions will be unequally retarded, in proportion to their densities.

Retarded motion from gravity, is peculiar to bodies projected upwards, and this, in the same manner as a falling body is accelerated; only in the latter, the force of gravity acts in the same direction with the motion of the body; and in the former in an opposite direction.

As it is the same force which augments the motion in the falling, and diminishes it in the rising body, a body will rise till it has lost all its motion; which it does in the same time wherein a body falling would have acquired a velocity equal to that wherewith the body was projected upwards.

RETE MIRABILE, in anatomy, a small plexus, or net-work of vessels in the brain, surrounding the pituitary gland.

The rete mirabile is very conspicuous in brutes, but either not existent in man, or so very minute that its existence is fairly doubted.

RETENTION is defined, by Mr. Locke, to be a faculty of the mind, whereby it keeps, or retains, those simple ideas it has once received, by sensation or reflection.

RETENTION is also used, in medicine, &c. for the state of contraction in the solids or vascular parts of the body, which makes them hold fast their proper contents.

RETICENCY, *Reticentia*, a figure in rhetoric whereby we make oblique mention of a thing, in pretending to pass it over unmentioned.

RETICULA, or RETICULE, in astronomy, a contrivance for the exact measuring the quantity of eclipses.

The reticule is a little frame, consisting of thirteen fine silken threads, equidistant from each other, and parallel, placed in the focus of object glasses of telescopes; that is, in the place where the image of the luminary is painted in its full extent: of consequence, therefore, the diameter of the sun or moon is hereby seen divided into twelve equal parts or digits; so that to find the quantity of the eclipse, there is nothing to do but to number the luminous and dark parts. As a square reticule is only proper for the diameter, not for the circumference, of the luminary, it is sometimes made circular by drawing six concentric equidistant circles. This represents the phases of the eclipse perfectly.

RETICULAR BODY, *Corpus reticulare*, in anatomy, a very fine membrane, perforated, in the manner of a net, with a multitude of foramina. It is placed immediately under

R E T

under the cuticle, and when that is separated from the cutis, whether by art or by accident, this adheres firmly to it, and is scarce possible to be parted from it, seeming rather to be its inner superficies than a distinct substance. In regard to this, we are to observe, first, the places in which it is found, being all those in which the sense of feeling is most acute, as in the palms of the hands, the extremities of the fingers, and on the soles of the feet. The tongue, however, is the part where it is most accurately to be observed: it is more easily distinguishable there than any where else, and its nature and structure are most evidently seen there.

Its colour in the Europeans is white, but in the Negroes, and other black nations, it is black; in the tawny it is yellowish: the skin itself in both is white; and the blackness and yellowness depend altogether on the colour of this membrane.

The uses of the corpus reticulare are to preserve the structure of the other parts of the integuments, and keep them in their determinate form and situation. Its apertures give passage to the hairs, and let through the papillæ and excretory ducts of the skin: it retains these in a certain and determinate order, that they cannot be removed out of their places, and has some share in preserving the softness of the papillæ, which renders them fit for the sense of feeling.

RETICULAR PLEXUS, *Plexus Reticularis*, sometimes denotes the choroides, which is thus called because its fibres are interwoven like a net.

RETICULUM, the caul or omentum, a name sometimes given to this part, from its net-like structure.

RETIFORMIS LACIS, in anatomy, the same with the rete mirabile. See **RETE**.

RETINA, in anatomy, the expansion of the optic nerve on the internal surface of the eye, whereupon the images of objects being painted, are impressed, and by that means conveyed to the common sensory in the brain, where the mind views and contemplates their ideas.

RETINUE, *Retinentia*, the attendants or followers of a prince or person of quality, chiefly in a journey.

RETIRADE, in fortification, a kind of retrenchment made in the body of a bastion, or other work, which is to be disputed, inch by inch, after the defences are dismantled. It usually consists of two faces, which make a re-entering angle. When a breach is made in a bastion, the enemy may also make a retirade or new fortification behind it.

RETORT, in chemistry, a kind of crooked matrass, or a round bellied vessel, either of earth or glass, with a slender crooked beak, to which the recipient is to be placed. For the figure and method of using the retort, see **DISTILLATION**.

RETRACTION, *Retractio*, the act of drawing back, or unsaying what a person had said before.

Among anatomists, retraction frequently signifies the contraction or shortening of any part.

RETRACTS, among horsemen, pricks in a horse's feet, arising from the fault of the farrier in driving nails that are weak, or in driving them ill pointed, or otherwise amiss.

RETRAHENS Auriculum, in anatomy, a muscle of the external ear, consisting of a parcel of fleshy fibres, which in some bodies are divided into distinct muscles, arising from the os temporale, and fixed to the hind-part of the concha. But these muscles are so small in men that the auricle is seldom moveable at all.

RETREAT, in war, the retiring or moving back again of any army or part thereof.

RETREAT, in naval affairs, the order or disposition in which a squadron of ships retires from a superior or victorious enemy.

When a fleet is obliged to retreat in fight of an enemy, the best way to secure it will be by sailing in a kind of half moon; the admiral's ship forming the obtuse angle, his fleet being equally divided, one half on the star-board and the other half on the lar-board side; keeping the fire-ships, transports, &c. in the middle.

R E T

This manner of ranging a fleet seems the most advisable, because the enemy can never approach those who endeavour to escape without exposing themselves, at the same time, to the fire of the admiral, and that of his seconds.

If the commander in chief thinks this form gives too great an extent to his fleet, he may easily close his wings or quarters.

The most natural course in this form of sailing is to steer away before the wind: but, if necessary, the ships may bear away large upon either tack, or even keep close upon a wind.

RETREAT, or **RELAY**, in masonry, a little recess or diminution of the thickness of a wall, rampart, &c. in proportion as it is raised. The retreat, properly, is the diminution of a wall without-side, or the contraction of its upper courses more than the foundation. Where the foundation is very long, they usually make two or three retreats.

RETRENCHMENT literally signifies something cut off or taken from a thing; in which sense it is the same with subtraction, diminution, &c.

RETRENCHMENT, in the art of war, any kind of work raised to cover a post, and fortify it against the enemy, such as fascines loaded with earth, gabions, barrels of earths, sand-bags, and generally all things that can cover the men and stop the enemy. But retrenchment is more particularly applicable to a foss bordered with a parapet; and a post fortified thus is called post retrenched, or strong post.

Retrenchments are either general or particular: general retrenchments are new fortifications made in a place besieged, to cover the besiegers when the enemy become masters of a lodgment on the fortification, that they may be in a condition of disputing the ground inch by inch, and of putting a stop to the enemy's progress in expectation of relief.

Particular retrenchments are such as are made in the bastions when the enemy are masters of the breach. These can never be made but in new full bastions, for in empty, or hollow ones, there can only be made retirades. The particular retrenchments are made several ways, according to the time they have to cover themselves: sometimes they are made before hand, which are certainly the best. The parapets of such retrenchments ought to be five or six feet thick, and five feet high, with a large and deep foss, from whence ought to run out small fougades and countermines.

RETRIBUTION, *Retributio*, a handsome present, gratuity, or acknowledgment, given instead of a formal salary, or hire, to persons employed in affairs that do not so immediately fall under estimation, nor within the ordinary commerce in money.

RETRIEVE, to recover, get again, or repair a thing lost or damaged.

RETROCESSION, *Retrocessio*, the act of going backwards; more usually called retrogression, or retrogradation. See the next article.

RETROCESSION of the Equinox. See the article **PRECESSION**.

RETROGRADATION, or **RETROGRESSION**, the act or effect of a thing moving backwards.

The retrograde motion of the planets is an apparent motion, whereby they seem, to an observer placed on the earth, to move backwards, or contrary to the signs.

The retrograde motion of the nodes, is a motion of the line of nodes, whereby it continually shifts its situation from east to west, contrary to the order of the signs; completing its retrograde circulation in the compass of about nineteen years, after which time either of the nodes, having receded from any point of the ecliptic, returns to the same again.

RETROGRESSION of Curves, their bending or turning backwards. See the articles **FLEXURE** and **INFLECTION**.

RETROMINGENTS, in natural history, a class or division of animals, whose characteristic it is that they stale, or make water backwards, both male and female.

RETURN, *Returna*, or *Retorna*, in law, is used in divers senses. 1. Return of writs by sheriffs and bailiffs is a certificate made by them to the court, of what they have done in relation to the execution of the writ directed to them. This is wrote on the back of the writ by the officer, who thus sends the writ back to the court from whence it issued, in order that it may be filed. 2. Return of a commission, is a certificate or answer sent to the court from whence the commission issues, concerning what has been done by the commissioners. 3. Returns, or days in bank, are certain days in each term, appointed for the return of writs, &c.

RETURN, in building, is a side or part that falls away from the fore-side of any straight work.

RETURNS of a Trench, in fortification, are the turnings and windings which form the lines of a trench.

RETURNS of a Mine, in fortification, are the windings of the gallery.

REVE, **REEVE**, or **GREVE**, the bailiff of a franchise, or manor, thus called, especially in the west of England. Hence shire-reve, sheriff, port-greve, &c.

REVEILLE, a beat of drum about break of day, to give notice that it is time for the soldiers to arise, and that the centries are to forbear challenging.

REVELATION, the act of revealing, or making a thing public that was before unknown: it is also used for the discoveries made by God to his prophets, and by them to the world; and more particularly for the books of the Old and New Testament.

The principal tests of the truth of any revelation are, its being worthy of God, and consistent with his known attributes; its being agreeable to the clear dictates of unprejudiced reason, and its having a tendency to refine, purify, and exalt the mind of man to an imitation of the Deity in his moral perfections.

Mr. Locke, in laying down the distinct provinces of reason and faith, observes, 1. That the same truths may be discovered by revelation, which are discoverable to us by reason. 2. That no revelation can be admitted against the clear evidence of reason. 3. That there are many things of which we have but imperfect notions, or none at all; and others, of whose past, present, or future existence, by the natural use of our faculties we cannot have the least knowledge: and these, being beyond the discovery of our faculties, and above reason, when revealed, become the proper object of our faith. He then adds, that our reason is not injured or disturbed, but assisted and improved by new discoveries of truth coming from the fountain of knowledge.

Whatever God has revealed is certainly true: but whether it be a divine revelation or no, reason must judge, which can never permit the mind to reject a greater evidence to embrace what is less evident. There can be no evidence that any traditional revelation is of divine original, in the words we receive it, and the sense we understand it, so clear and so certain, as that of the principles of reason: and, therefore, nothing that is contrary to the clear and self-evident dictates of reason, has a right to be urged or assented to as a matter of faith, wherein reason has nothing to do. Whatsoever is divine revelation ought to over-rule all our opinions, prejudices, and interests, and has a right to be received with full assent: and such a submission as this, of our reason to faith, takes not away the landmarks of knowledge.

REVELATION of St. John, the same with the apocalypse. See **APOCALYPSE**.

REVELS, entertainments of dancing, masking, acting, comedies, farces, &c. anciently very frequent in the inns of court, and in noblemen's houses, but now much disused. The officer who has the direction of the revels at court, is called the master of the revels.

REVENUE, the annual income a person receives from the rent of his lands, houses, interest of money in the stocks, &c.

REVENUE, in hunting, a fleshy lump formed chiefly of a cluster of whitish worms on the heads of deer, supposed to occasion their casting their horns by gnawing them at the roots.

REVENUE is also used for a new tail of a partridge, growing after the lop of a former; this is measured by fingers; and thus they say a partridge of two, three, or four fingers revenue.

REVERBERATION, *Reverberatio*, in physics, the act of a body repelling or reflecting another after its impinging thereon.

REVERBERATION, in chemistry, denotes a kind of circulation of the flame by means of a reverberatory, or the return of the flame from the top of the furnace back to the bottom, chiefly used in calcination. Reverberation is of two kinds: the first with a close fire, that is, a reverberatory furnace, where the flame has no vent a-top, being covered with a dome or capital, which repels its action back on the matter or the vessel that contains it, with increased vehemence. After this manner is refining, the distillation of acids, spirits, &c. performed. Reverberation with an open fire is that performed in a furnace or reverberatory, whose registers are all open, used in calcination, &c. See the next article.

REVERBERATORY, or **REVERBERATING FURNACE**, a chemical furnace built close all around, and covered at the top with a capital of brick or tiles, so as not to give any vent to the heat or flame, but to determine it to reverberate or turn back from the brick-work with new force upon the matter placed at bottom. When the fire has no vent or passage a-top, it is a whole reverberatory. When the middle of the capital is open, and only the sides close, so that there is only a half circulation of the flame, it is called an half reverberatory. The reverberatory furnace is chiefly used in the fusion and calcination of metals and minerals, and on other occasions where the most intense heat is required, as in assaying, &c. whence it is also called the melting furnace, and assaying furnace. See the article **CHEMICAL LABORATORY**.

REVEREND, *Reverendus*, a title of respect given to ecclesiastics.

REVERIE, the same with delirium, raving, or distraction. See **DELIRIUM**, &c.

It is used also for any ridiculous, extravagant imagination, action, or proposition, a chimera or vision. But the most ordinary use of the word, among English writers, is for a deep disorderly musing or meditation.

REVERSE, in law, &c. To reverse signifies to undo, repeal, or make void.

REVERSE of a Medal, Coin, &c. denotes the second or back-side, in opposition to the head or principal figure.

REVERSE, in fencing, a back stroke.

REVERSED, in heraldry, a thing turned backwards, or upside down.

REVERSION, *Reversio*, in law, is defined to be returning of lands, &c. into the possession of the donor, or his heirs.

Reversion, in the law of England, has two significations; the one of which is an estate left, which continues during a particular estate in being; and the other is the returning of the land, &c. after the particular estate is ended; and it is further said, to be an interest in lands, when the possession of it fails, or where the estate which was for a time parted with, returns to the grantors, or their heirs. But, according to the usual definition of a reversion, it is the residue of an estate left in the grantor, after a particular estate granted away ceases, continuing in the grantor of such an estate. The difference between a remainder and a reversion, consists in this, that the remainder may belong to any man except the grantor; whereas the reversion returns to him who conveyed the lands, &c. See **INTEREST**.

REVERSION of Series, in algebra, a kind of reversed operation of an infinite series.

REVIEW, in chancery, is used for a bill, where a cause has been heard, and a decree thereon signed; but some error in law appearing upon the decree, or new matter being discovered after it was made, this bill is given for a fresh examination into the merits of the cause.

REVIEW, in war, is the appearance of an army, or part of an army, in order of battle, and their being viewed by the general, that he may know the condition of the troops, see that they are complete, and be a witness of the expertness with which they perform their evolutions and other exercises.

REVISE, among printers, a second or third proof of a sheet to be printed, taken off in order to be compared with

with the last proof, to see whether all the mistakes marked in it are corrected.

REVIVIFICATION, in chemistry, the same with resuscitation. See **RESUSCITATION**.

REVOLUTION, in politics, signifies a grand change or turn in government.

In geometry, the revolution of any figure, is its motion quite round a fixed line, as an axis.

The revolution of a planet, or comet, round the sun is nothing but its course from any point of its orbit till its return to the same.

REVULSION, in medicine, turning a flux of humours from one part to another, by bleeding, cupping, friction, sinapisms, blisters, fomentations, bathings, issues, setons, strong purging of the bowels, &c. Dr. Van Swieten, in his Commentaries upon the Aphorisms of Boerhaave, observes, that the use of revulsions in diseases, is confirmed by daily experience as well as by reason; for so soon as the resistance to the blood's motion is either diminished or totally removed in any part of the body, it immediately flows into that part with a greater velocity.

RHABDOIDES, in anatomy, the same with the sagittal suture of the skull.

RHABDOLOGY, in arithmetic, the doctrine of Neper's rods. See **NEPER**.

RHABDOMANCY, *ραβδομαντεία*, a species of divination performed by means of rods. See the article **DIVINATION**.

RHACHITIS, in medicine, the rickets. See the article **RICKETS**.

RHAGADES, in medicine, denotes chaps or clefts in any part of the body; arising either from an acidity of the parts, or acrimony of the humours; in both which cases, cooling and emollient applications are proper.

RHAMNUS, in botany. See the articles **ALATERNUS**, **JUJUBES**, and **BUCK-THORN**.

RHAPHONTICUM is the name for the root of the rheum. See **RHEUM**.

RHAPSODI, *ραψοδοί*, *Rhapsodists*, in antiquity, persons who made a business of singing pieces of Homer's poems. Cuper informs us, that the Rhapsodi were clothed in red when they sung the Iliad, and in blue when they sung the Odyssey. They performed on the theatres, and sometimes strove for prizes in contests of poetry, singing, &c. After the two antagonists had finished their parts, the two pieces or papers they were written in were joined together again: whence the name, viz. from *ραπτω*, *suo*, and *ωδῆ*, *canticum*: but there seems to have been other Rhapsodi of more antiquity than these people, who composed heroic poems or songs in praise of heroes and great men, and sung their own compositions from town to town for a livelihood, of which profession Homer himself is said to be.

RHAPSODOMANCY, an ancient kind of divination performed by pitching on a passage of a poet at hazard, and reckoning on it as a prediction of what was to come to pass.

RHAPSODY, *ραψωδία*, in antiquity, a discourse in verse sung or rehearsed by a Rhapsodist. Others will have rhapsody to signify a collection of verses, especially those of Homer, which having been a long time dispersed in pieces and fragments, were at length, by Pisistratus's order, digested into books called rhapsodies, from *ραπτω*, *suo*, and *ωδῆ*, *canticum*. Hence, among moderns, rhapsody is also used for an assemblage of passages, thoughts, and authorities raked together from divers authors, to compose some new piece.

RHETORIANS, a sect of heretics in Egypt, so denominated from Rhetorius their leader. The distinguishing doctrine of this heresiarch, as represented by Philastrius, was, that he approved of all the heresies before him, and taught that they were all in the right.

RHETORIC, *Rhetorica*, the art of speaking copiously on any subject, with all the advantage of beauty and force.

Lord Bacon defines rhetoric very philosophically, to be the art of applying and addressing the dictates of reason to the fancy, and of recommending them there so as to affect the will and desires. The end of rhetoric, the same author observes, is to fill the imagination with ideas

and images which may assist nature without oppressing it. Vossius defines rhetoric, the faculty of discovering what every subject affords of use for persuasion. Hence, as every author must invent arguments to make his subject prevail, dispose those arguments, thus found out, in their proper places, and give them the embellishments of language proper to the subject; and if this discourse be intended to be delivered in public, utter them with that decency and force which may strike the hearer; rhetoric becomes divided into four parts, invention, disposition, elocution, and pronunciation.

Rhetoric and oratory differ from each other as the theory from the practice; the rhetorician being he who describes the rules of eloquence, and the orator he who uses them to advantage. Ordinarily, however, the two are used indifferently for each other.

RHEUM, *ρευμα*, a thin serous humour, occasionally issuing out of the glands about the mouth and throat.

RHEUM, the **RHAPHONTIC PLANT**, in botany, a genus of plants, the corolla whereof consists of a single petal, which is narrow at the base and impervious: the limb is divided into six obtuse segments, alternately smaller: there is no pericarpium: the seed is single, large, triquetrous, acute, and surrounded with membranaceous rims.

The root of this plant, which appears evidently to have been the rhubarb of the ancients, is by many confounded with the modern rhubarb, though considerably different both in appearance and quality. The raphontic root is of a dusky colour on the surface, of a loose spongy texture, considerably more astringent, but less purgative than the rhubarb; in this last intention two or three drams are required for a dose. It is an ingredient in the Venice-treacle, and in some of the colder compositions of the shops, but in these rhubarb is generally used in its place.

RHEUMATISM, in medicine, a distemper that happens most commonly in spring or autumn, when there is a remarkable change of air from hot to cold, and from cold to hot, when the wind suddenly shifts to any opposite point. It begins, according to Sydenham, with a shivering and other symptoms of a fever, and in a day or two's time, or sometimes sooner, a vehement pain seizes one or more of the limbs, raging sometimes in one place and sometimes in another, especially in the arms, wrists, shoulders, and knees: very often there is a redness and swelling, and the fever gradually goes off while the pain remains. This distemper often runs out into a great length, continuing sometimes for some months or years, not perpetually with the same violence, but coming and going, and from time to time renewing its paroxysms.

It chiefly attacks persons in the flower of their age, after violent exercise, or a great heat of the body from any other cause, and then being too suddenly cooled. Its proximate cause Boerhaave takes to be an inflammation of the lymphatic arteries of the membranes near the ligaments of the joints, but not so violent as to bring on a suppuration. This disease is nearly a-kin to the gout and scurvy, and the blood is like that of those afflicted with the pleurisy. The pain is exasperated upon the least motion: it sometimes attacks the loins and coxendix, and sometimes the brain, lungs, and viscera: when it seizes the loins it is then called lumbago; in this case, Sydenham observes that there is a most violent pain in the small of the back, which sometimes extends to the os sacrum, and is like a fit of the gravel, only the patient does not vomit. If this disease is unskilfully treated, it may continue several months or years, but not always with the same violence, but by fits. If it continues and increases, it may cause a stiff joint, which will scarce yield to any remedy.

Sydenham directs to take away ten ounces of blood on the side affected; this must be repeated three or four times, or oftener, once every other or every third day, according as the strength of the patient will bear. The diet must be very thin, and an emulsion of the four cold seeds may be given; as also a pultice of white bread and milk, tinged with a little saffron, may be laid to the part affected; a clyster of milk and sugar may be injected on those days the bleeding is omitted. If the patient cannot bear frequent bleeding, after the second or third time give the common

common purging potion every other day, and an ounce of diacodium at night, till he recovers.

In an incipient rheumatism of the shoulders, Hoffman says that nothing is better than a blister laid between the scapulæ; but if it happens to the plethoric, cupping, with scarification in the lower parts, repeated every month, does signal service. The same physician thinks it may be proper to chew rhubarb, from two scruples to a dram, with raisins or currants, two or three times a week.

The spirit of hartshorn and the balsam of guaiacum, given in the quantity of twenty or thirty drops, three or four times a day, Dr. Shaw says, is of great service: but he thinks nothing better than a decoction of the sudorific woods, to the quantity of a quart a day, for a month or six weeks together. This last, when assisted with crude antimony and mercurius dulcis, Hoffman recommends in the venereal rheumatism, which often arises from the remains of a lues venerea contained in the mass of blood. In a scorbutic rheumatism, or that arising from the scurvy, Sydenham directs the patient to take the scorbutic electuary and water, if he cannot bear any kind of evacuation.

He observes, that young persons who live temperately may be cured by a simple refrigerating diet, and moderate nourishing, with as much certainty as by repeated bleeding: for instance, let the patient live four days upon whey alone; and after that white-bread may be allowed for dinner, and on the last day of his illness he may be allowed it for supper. When the symptoms cease he may have boiled chickens, or any thing of easy digestion, but every third day he must live upon whey only, till his strength returns. Boerhaave's method of cure is to the same effect, only he advises warm baths and strong blisters to be laid upon the part affected, nay even cauteries themselves: but Hoffman observes that great caution should be used with regard to topics, for if the patient's constitution is sanguineous they should all be avoided, and the part covered carefully with the bed-cloaths; but if there is a thick, cold, stagnating humour in the part, and a sense of cold, with a stricture of the pores, then frictions may be used with rough warm cloths, and afterwards cupping with scarifications. If the part becomes stiff and inflexible, with a numbness, which is called a parestis, then take human or canine axungia, two ounces; balsam of Peru, and oil of cloves, each two drams; with which make a liniment for the part: this has been known to have a wonderful effect. Arbuthnot says that cream of tartar in water-gruel, taken for several days, will abate the pains and swellings considerably by its acidity, correcting the alkaline salts of the blood.

Cheyne says, that the hot and inflammatory rheumatisms have all the symptoms of the gout, and like it, change from place to place, and by over violent evacuations may be translated upon the noble organs.

RHEXIS, among oculists, denotes a rupture of the cornea of the eye.

RHINE LAND *Rod*, in fortification, &c. a measure of two fathoms, or twelve feet, used by the Dutch and German engineers, &c.

RHINOCEROS, in zoology, the name of a genus of quadrupeds; so called from an horn growing on their nose.

Of this genus there are only two known species.
1. The rhinoceros with only one horn on its nose; and,
2. The rhinoceros with two horns.

In the year 1739 we had a young rhinoceros shewn in England, of which Dr. Parsons has given a very accurate account in the Philosophical Transactions.

The creature fed on rice, sugar, and hay; his keeper used to mix the rice and sugar in the following manner: seven pounds of rice and three pounds of sugar made the provision for one day; he eat this at three meals: and besides this, he eat about a truss of hay every week, and a large quantity of greens that were brought to him, at different times, and of which he seemed more fond than of dried food. He drank often, and always was observed to swallow a large quantity of water at a time.

He appeared very peaceable in his temper, and bore to be handled on any part of his body with great patience, except when he was hungry; but he was then always

outrageous, as also when he was struck. His most violent passions, even on the last occasion, were however always immediately appeased by giving him victuals.

Notwithstanding the lumpish aspect, and heavy make of this creature, he would jump about very nimbly in his fits of passion, and often leap to a great height; and one common mark of his fury was the striking his head against the walls, or any thing else that was in the way, and this he would do with terrible violence. He was very apt to fall into these passions in a morning before his rice and sugar were given him, and from the whole he appeared quite untractable, and seemed able, in his passions, to have run so fast, as that a man on foot could not have escaped him.

This creature was two years old, and did not exceed a young heifer in height, but was remarkably broad and thick. His head was very large; and the hinder part of it, near the ears, remarkably elevated above the rest of the face, which was flat, and sunk down in a remarkable manner in the middle, rising again towards the origin of the horn, but in a much smaller degree. The horn stands upon the nose of the animal as upon a sort of hill; and when the skeleton of the head is seen, that part of the skull on which the horn is fixed, is found to rise into a blunt cone, to answer to a cavity in the basis of the horn, which is very hard and solid; in other respects having no manner of hollow or core, like those of other quadrupeds. The horn in this young animal did not rise above an inch high from its tough basis, and was black and smooth at the top, but ragged downwards; and the determination of its growth is backwards, not straight up; this is very evidently seen in the horns of old rhinoceroses, which are always curved in a considerable degree that way. If we consider the proportion of this animal's size to the length of its horn, and thence carry the proportion to that between the large horns we see in the museums of the curious, we must suppose the animal of a very stupendous size, when at its full growth. *Phil. Transf. N^o. 470.*

The sides of the under jaw, in this creature, stand very wide asunder, slanting outwards to the lower edge, and backwards to the neck; the edges turn outwards from this structure of the bones, and the head necessarily looks very large. That part of the head which reaches from the fore part of the horn to the upper lip may be called the nose; this is very thick and bulky, and has a kind of circular sweep down towards the nostrils; on all this part there are a great number of rugæ or wrinkles.

The nostrils are situated very low, in the same direction with the opening of the mouth, and not more than an inch from it; and when viewed in a fore-view, the whole nose, from the top of the horn to the verge of the lower lip, is shaped like a bell. The under lip is like that of an ox, but the upper more like that of a horse, and he uses it as that creature does, to gather up hay from the rack, or grafs from the ground; but with this superior advantage, that this creature has a power of extending this lip to six or seven inches in length from the nose, and there drawing it to a point; with this lip, thus extended, the creature is able to grasp a stick, or any small substance, and hold it extremely fast; and this power of prolonging the lips serves, in many purposes, to the same end as the trunk of that other unwieldy animal the elephant.

The tongue of the rhinoceros is said to be so rough as to be able to rub a man's flesh off from the bones; but in this young subject it was so soft, that it resembled that of a calf. It may possibly grow harder with age; but the story of its effects seems of a piece with the many other false marvels reported of this animal. The eyes are dull and sleepy, much like those of a hog in shape; he seldom opens them entirely; and it is to be observed, that they are situated nearer the nose than those of any other known quadruped. The ears are broad and thin towards the top, much like those of a hog; but they arise each from a narrow round base, with some wrinkles on it, which issues out of a sinus as it were surrounded with a fleshy fold. The neck is very short, and has two folds or wrinkles, wholly surrounding it, only that the anterior one is broken underneath; and has a flap hanging from it so deep, that it would contain a man's hand; from the middle

middle of the posterior plica of the neck, there arises another, which passing backward, is lost before it reaches the body. The shoulders are thick and heavy, and have each a fold passing downwards. The body is very large and thick, and stands out at the sides like that of a cow with calf. The legs are very thick and strong; they are round, and somewhat smaller downwards than in the upper part; and when the creature stands upright, they bend inwards at the knee, so that they are nothing like straight. In some quadrupeds the fetlock bends to the weight of the animal, but in this creature there is no appearance of any such bending, so that he seems to stand upon four stumps, especially when viewed behind. He has three hoofs upon each foot forward, but the back part is a great mass of flesh, rough like the rest of the skin; and the sole of the foot is very plump and callous in the surface, but easily yielding to the pressure from the softness of the subjacent flesh. Its shape is like that of a heart, with a blunt apex before, and a broad base behind. The tail is very small in proportion to the size of the animal, not exceeding seventeen or eighteen inches in length, and but thin or slender; it is very rough, and has a kind of twist or stricture towards the extremities, ending in a flat mass; this gave occasion to some authors to compare the whole tail to a spatula; on the sides of this flat part, there grew a few short but very thick and strong black hairs, but these grow much longer in the more advanced state of the creature; and are not round, like other hairs, but flat, like small pieces of whalebone. The creature has no other hair about it, except a very small quantity at the edge of the ears.

The penis of the male rhinoceros is of a very remarkable structure, being inclosed in two cases. The female differs in nothing from the male except in the pudenda, which are shaped like those of a cow.

The skin of the rhinoceros is thick, and seems almost impenetrable; it feels like a piece of board of half an inch thick. It is covered in all parts, more or less, with a sort of incrustations resembling scales. These are small on the neck, and largest of all in the shoulders and hips; between the folds of this thick skin, the cuticle, which is left bare, is soft, and easily penetrable. The scabby incrustations of the skin have been called scales, by some writers; but this is a very wrong term, for they have nothing of the nature of scales, nor any thing of regularity in them.

The creature is of the retromingent, and therefore probably of the retrogenerative kind; the penis, when erect, is not more than nine, or at the utmost ten inches long, and is curved backwards at the end. This was the description of the rhinoceros shewn in England at this time, and of all the others that have been seen in this part of the world, as to the general characters; but tho' these creatures which we have seen, have but one horn, it is very certain that there is a species of rhinoceros which has two. Martial has mentioned a rhinoceros, as shewn in the amphitheatre at Rome, which had two horns; but his commentators, supposing the copies erroneous, have been at great pains to alter it, so as to make it express what they had seen or heard of, that is, a rhinoceros only with one horn; but it appears from almost indisputable testimony, that there not only is in nature such a rhinoceros with two horns, but that such were shewn in the public sports at Rome, and therefore the text seems to have been very right, and the commentators in the wrong. The creatures we have seen have indeed only had one horn; and the accounts of travellers, and the great number of horns preserved in the cabinets of the curious, which are all single, seem to prove this; but, though the rhinoceroses of Asia are all one-horned, yet it is certain, that there is a kind found in Africa which has two horns, and it is known, that the Romans had beasts from this last part of the world as well as the other. Peter Kolbe, in his Voyage to the Cape of Good-Hope, describes rhinoceroses which he saw, and which had a horn on the nose, and another close behind it. Sir Hans Sloane's museum affords two horns of a rhinoceros, standing just as this author has described them, which are still fixed to the same integument; and we are convinced of the Romans being acquainted with this

species, from a brass medal of Domitian, which has on it a rhinoceros, with two horns on the nose placed in this manner.

Redi, who has been very sagacious in discovering the falsity of many of the pretended medicines taken from animals, yet gives us on the testimony of his own experience, an account of some very remarkable virtues in the parts of the rhinoceros. The blood he assures us is excellent in cholics and dysenteries. The decoction of the skin, he assures us, is a grand stomachic antidote; and the horns are very valuable and alexipharmic.

RHODIUM, or **ROSEWOOD**, the wood or root of a tree, of which we have no certain account; brought from the Canary islands, in long crooked pieces, full of knots, externally of a whitish colour, internally of a deep yellow, with a reddish cast. The largest, smoothest, straightest, heaviest, and deepest-coloured pieces should be chosen; and the small, thin, pale, light ones rejected.

This wood has a slightly bitterish, somewhat pungent, balsamic taste, and a fragrant smell, especially when scraped or rubbed, resembling that of roses. Digested in rectified spirit, it gives out pretty readily the whole of its active matter, and tinges the menstruum of a reddish yellow colour: on committing to distillation the filtered tincture, the spirit brings over little or nothing of its flavour; the fine smell, as well as the balsamic pungency, of the rhodium, remaining nearly entire in the inspissated extract, which proves tenacious and adhesive like the turpentine. Infused in water, it gives out likewise great part of its smell and taste, together with a bright yellow colour: in evaporation, the water carries off the specific flavour of the wood, leaving in the extract only a slight pungency and bitterishness. Distilled with water, it gives over, somewhat difficultly and slowly, a highly odoriferous essential oil, at first of a gold colour, by age turning reddish; amounting, if the rhodium is of a good kind, to about one ounce from fifty: the distilled water is likewise agreeably impregnated with the fragrance of the rhodium, and greatly resembles that of damask roses.

The essential oil is used as a perfume, for scenting pomatums, &c. and in this light only the rhodium wood is generally regarded. It promises, however, to be applicable to more important purposes, and bids fair to prove a valuable cordial and corroborant.

Jamaica affords a wood called by the people there rose-wood; which, though not the rhodium of the shops, has nevertheless much of the smell: it is described by Sir Hans Sloane to be a tree growing to twenty or more feet in height, and thick enough to afford the largest segments we ever meet with of it; and possibly an adulteration of the true rhodium with this wood may be the true cause why the rhodium is not allowed to be the root, but a species of cytisus, as Hoffman affirms.

The flowers of the Jamaica rose-wood are small and white, consisting of three petals, and standing in clusters: the fruit is a berry of the size of a pepper-corn, and the leaves of the tree are pinnated.

RHOMBOIDES, in geometry, a quadrilateral figure, whose opposite sides and angles are equal, but is neither equilateral nor equiangular.

RHOMBOIDES, in anatomy, a thin, broad, and obliquely square fleshy muscle, situated between the basis of the scapula and the spina dorsi; so called from its figure. Its general use is to draw, backward and upward, the subspinal portion of the basis scapulæ.

RHOMBUS, in geometry, an oblique-angled parallelogram, or quadrilateral figure, whose sides are equal and parallel, but the angles unequal, two of the opposite ones being obtuse, and the other two acute.

RHUBARB, *Rhabarbarum*, a plant with large dock-like leaves, among which arises a single thick stalk, bearing loose clusters of naked monopetalous bell shaped white flowers; each of which contains nine stamina, of which the docks, strictly so called, have but six, and is followed by a triangular seed surrounded about the edges with a leafy margin. It is perennial. It is a native of China and Siberia, and has lately been raised in some of our gardens, where it is found to grow with vigour in the open ground.

Two sorts of rhubarb roots are met with in the shops. The first is imported from Turkey and Russia, in roundish pieces, freed from the bark, with a hole through the middle of each, externally of a yellow colour, internally variegated with lively reddish streaks. The other, which is less esteemed, comes immediately from the East Indies, in longish pieces, harder, heavier, and more compact than the foregoing. The first sort, unless kept very dry, is apt to grow mouldy and worm-eaten: the second is less subject to these inconveniencies. Some of the more industrious artists are said to fill up the worm holes with certain mixtures, and to colour the outside of the damaged pieces with powder of the finer sorts of rhubarb, and sometimes with cheaper materials. The marks of the goodness of rhubarb are, the liveliness of its colour when cut; its being firm and solid, but not flinty or hard; its being easily pulverable, and appearing when powdered of a fine bright yellow colour; its imparting to the spittle, on being chewed, a deep saffron tinge; and not proving slimy or mucilaginous in the mouth. Its taste is sub-acrid, bitterish, and somewhat styptic; the smell, lightly aromatic.

Rhubarb is a mild cathartic, and commonly looked upon as one of the safest and most innocent of the substances of this class. Besides its purgative virtue, it has a mild astringent one, discoverable by the taste, and by its striking an inky blackness with chalybeate solutions: hence it is found to strengthen the tone of the stomach and intestines, to leave the belly costive, and to be one of the most useful purgatives in diarrhæas, dysenteries, and all disorders proceeding from a debility and laxity of the fibres: it is frequently indeed given with a view rather to this stomachic corroborating virtue, than to its producing any considerable evacuation. It tinges the urine of a light yellow colour.

Rhubarb in substance purges more effectually than any preparation of it: the dose is from a scruple to a dram. By roasting it with a gentle heat, till it becomes easily friable, its cathartic power is diminished, and its astringency supposed to be increased. In its habitude to menstrua, it differs remarkably from most of the other cathartic drugs, its purgative virtue being extracted far more perfectly by water than by rectified spirit: the root remaining after the action of water is almost, if not wholly, inactive; whereas, after repeated digestion in spirit, it proves still very considerably purgative: the colour of both tinctures is a fine deep yellow, that of the spirituous palest; when the rhubarb has given out to spirit all that this menstruum can extract, it still imparts a deep colour, as well as a purgative impregnation, to water. The watery infusion, in being inspissated by a gentle heat, has its virtue so much diminished, that a dram of the extract is said to have scarcely any greater effect than a scruple of the root in substance: the spirituous tincture loses less; half a dram of this extract proving moderately purgative, though scarcely more so than an equal quantity of the powder. The spirituous extract dissolves almost wholly in water; and hence the tincture does not, like the spirituous infusions of most other vegetables, turn milky on being mixed with aqueous liquors: of the watery extract, scarce above one fourth is dissolved by rectified spirit, and the part that does not dissolve proves more purgative than that which does.

Tinctures of this root are drawn in the shops with proof spirit and with mountain wine, in the proportion of an ounce of the rhubarb to a pint of the menstruum. These preparations, used chiefly as mildly laxative corroborants, in weakness of the stomachs, indigestion, diarrhæas, cholicky, and other like complaints, are commonly aromatized with a little cardamom seeds and saffron, as two drams of the former and one of the latter to the above quantity of the root. For some purposes, a tincture is drawn from the rhubarb and cardamom seeds with proof spirit, and two ounces of white sugar-candy dissolved in the strained liquor. For others, instead of sweets and aromatics, gentian and snake root are joined, in the proportion of a dram and a half of the former and a dram of the latter, with the addition of a scruple of cochineal as a colouring ingredient: this last tincture is, in many cases, an useful assistant to the Peruvian bark in the cure of intermittents.

The Turkey rhubarb is, among us, universally preferred to the East India sort, though this last appears to be for some purposes at least equal to the other. It is manifestly more astringent, but has somewhat less of an aromatic flavour. Tinctures made from both with equal quantities of rectified spirit, have nearly the same taste: on drawing off the menstrua, the extract left by the tincture of the East India rhubarb proves in taste considerably stronger than the other. Both sorts appear to be the produce of the same climate, and the roots of the same species of plant, taken up probably at a different season, or cured in a different manner.

RHUMB, in navigation, a vertical circle of any place, or the intersection of such a circle with the horizon. Therefore, rhumbs coincide with the points of the world, or of the horizon; and hence navigators distinguish the rhumbs by the same name as the points and winds. See COMPASS.

RHUMB LINE, in navigation, the line which a ship describes, keeping in the same collateral point or rhumb. See COURSE.

RHYME, in poetry, a similitude of sound between the last syllable or syllables of two verses. Rhymes may be distinguished into whole or perfect, and half or imperfect rhymes. The first is where there is a similitude of sound without any difference, the latter where there is a difference either in the pronunciation or orthography. The French distinguish their rhymes into masculine and feminine. The feminine is where the last syllable of the rhyme ends with an *e* mute, in as *dove*, *belle*, &c. The masculine rhymes are those of all other words.

Rhyme is a modern invention, the product of a Gothic age. Milton calls it the modern bondage, yet some authors will have it that the English, French, &c. borrow their rhyme from the Greeks and Latins, who affected a certain cadence or period ending in a consonant. This affectation increased, as the Latin tongue declined; so that among the Latin writers scarce any thing is more common than rhyming periods. In the twelfth century, particularly, Latin rhyme was much in vogue, under the name of Leonine verses. The French, and from them the English, retain this cadence of rhyme, which seemed more agreeable than the measured verses of the Greek and Roman poets. The reader may see a collection of Latin rhymes of our ancient English writers, in Camden's Works. Since the restoration of learning in the sixteenth century, attempts have been made to banish rhyme from the modern poetry, and to settle the English and French verses on the footing of the ancient Greek and Latin ones, by fixing the quantity of the syllables, and trusting wholly to those and the numbers, or measure. Milton, Philips, Addison, Thomson, and some others, have excelled in this sort of blank verse. The French have attempted the same, but not succeeded; this kind of measure being inconsistent with the genius of the French tongue, which cannot vary the arrangement of the words, or change their situation, as this kind of verse requires. Nor indeed can any of the modern tongues equal the ancient in this respect; yet none more than the English, nor less than the French. *Dict. Tre-voux*.

RHYTHM, or RHYTHMUS, in music, the variety in the movement as to the quickness or slowness, length or shortness of the notes.

Or rhythmus may be defined, more generally, the proportion which the parts of a motion have to each other.

Aristides, among the ancient musicians, applies the word rhythmus three ways, viz. either to immoveable bodies when their parts are rightly proportioned to each other, as a well-made statue, &c. or to things that move regularly, as handsome walking, in dancing, in the dumb shews of pantomimes, &c. or, thirdly, to the motion of sound or voice; in which the rhythmus consists of long and short syllables, or notes, joined together in some kind or order, so as their cadence on the ear may be agreeable.

The rhythmus of the ancients was very different, as Mr. Malcolm observes, from that of the moderns; the former depended altogether on the poetry, and was only that of the long and short syllables of the words and verses,

and

and had no other forms or varieties than what the material art afforded. The changes therein are none but those made from one kind of metrum to another, as from iambic to choric.

In the modern music, the constitution of the rhythm differs from that of the verse so far, that, in setting music to words, the thing chiefly regarded is to accommodate the long and short notes to the syllables, in such a manner as that the words be well separated, and the accented syllables of each word so conspicuous, that what is sung may be distinctly understood.

Pancirollus seems of this opinion, and the reason he gives why the modern music is less perfect than the ancient, is, that we hear sounds without words.

Vossius adds, that the modern languages and verses are altogether unfit for music; and that we never shall have any right vocal music, till our poets learn to make verses capable to be sung, that is, till we new model our language, restore the ancient quantities and metrical feet, and banish our barbarous rhymes. Our verses, says he, run, as it were, all in one foot, so that we have not any real rhythmus at all in our poetry: he adds, that we mind nothing farther than to have such a number of syllables in a verse of whatsoever order; but this exaggeration in some respects is unjust.

RHYTHMICA, in the ancient music, that which considered the motions, regulated the measure, order, mixture, &c. so as to excite the passions, keep them up, augment, diminish, or allay them.

Aristides and other ancient musical writers divided artificial music into harmonica, rhythmica, and metrica.

But the rhythmica with them likewise comprehended dumb motions, and, in effect, all rhythmical, that is, regular motion.

RIAL, or **RYAL**, a Spanish silver coin. See **EXCHANGE**.

RIAL, or **ROYAL**, is also the name of a piece of gold anciently current among us for ten shillings.

RIBBAN, or **RIBBON**, in heraldry, the eighth part of bend.

RIBBAND, or **RIBBON**, a narrow sort of silk, chiefly used for head ornaments, badges of chivalry, &c.

In order to give our readers an idea of the manner in which this curious and valuable branch of manufacture is managed, we shall present him with a view of the ribbon-weaver in his loom, as represented in plate CIX. fig. 11. where 1 is the frame of the loom. 2. The castle, containing forty-eight pullies. 3. The branches, on which the pullies turn. 4. The tires, or the riding cords, which run on the pullies, and pull up the high-lisses. 5. The lift-sticks, to which the high-lisses are tied. 6. The high-lisses, or lifts, are a number of long threads, with platines, or plate-leads, at the bottom; and ringlets, or loops, about their middle, through which the cords or cross-threads of the ground-harness ride. 7. The plate-leads, or platines, are flat pieces of lead, of about six inches long, and three or four broad at the top, but round at the bottom; some use black slates instead of them: their use is to pull down those lisses, which the workman had raised by the treddle, after his foot is taken off. 8. The branches or cords of the ground harness, which go through the loops in the middle of the high-lisses: on the well ordering of these cords chiefly depends the art of ribbon-weaving, because it is by means of this contrivance that the weaver draws in the thread or silk that makes the flower, and rejects or excludes the rest. 9. The batton; this is the wooden frame that holds the reed, or shuttle, and beats or closes the work: where observe, that the ribbon-weaver does not beat his work; but as soon as the shuttle is passed, and his hand is taken away, the batton is forced by a spring from the top, to beat the work close. 10. The shuttle, or reed. 11. The spring of the batton, by which it is made to close the work. 12. The long-harness are the front-reeds, by which the figure is raised. 13. The linguas are the long pieces of round or square lead, tied to the end of each thread of the long harness, to keep them tight. 14. The broad piece of wood, about a foot square, leaning somewhat forward, intended to ease the

weaver, as he stoops to his shuttle; it is fixed in the middle of the breast-beam. Some weavers, instead of this, have a contrivance of a cord or rope, that is fastened to the front-frame, and comes across his breast; this is called a stop-fall. 15. The seat-bench; this leans forwards very much. 16. The foot-step to the treddles. 17. The breast-beam, being a cross-bar that passes from one of the standards to the other, so as to front the workman's breast; to this breast-bar is fixed a roll, upon which the ribband passes in its way to be rolled upon the roller, that turns a little below. 18. The clamps, or pieces of wood, in which the broaches, that confine the treddles, rest. 19. The treddles are long narrow pieces of wood, to the ends of which the cords, that moves the lisses, are fastened. 20. The treddle-cords are only distinguished from the riding cords by a board full of holes, which divide them, in order to prevent the plate-leads, which are tied to the high-lisses, from pulling them too high, when the workman's foot is off the treddle: which stop is made by a knot in the treddle-cord, too big to be forced through that hole in the board. 21. The lames are two pieces of thin narrow boards, only used in plain works, and then to supply the place of the long-harness. 22. The knee-roll, by which the weaver rolls up his ribbon, as he sees proper, or by bit and bit, as it is finished. 23. The back-rolls, on which the warp is rolled. It is to be observed, that there are always as many rolls as colours in the work to be wove. 24. The clamps, which support the rollers. 25. The returning sticks, or, as others call them, the returns, or the tumblers, or pullies, to which the tires are tied, to clear the course of cords through the high-lisses. 26. The catch-board, for the tumblers. 27. The tire-board. 28. The buttons for the knee-rolls and treddle-board, described in number 20.

Ribbons of all sorts are prohibited to be imported.

RIBBANDS, in ship-building, certain thin narrow planks, which are so made, that they may be easily bent to the timbers. That which is nailed to the stern-post at the height of the rising line, and to the mid ship-frame at the end of the rising of the floor-timbers, is called the floor ribband. That which answers to the wing-transom, and to the height of the lower deck on the mid-ship-frame, is called the breadth ribband: all the rest between these two are called intermediate ones.

These ribbands are nailed to all the frames from the stern-post to the stem, and when they are carried round, so as to make fair curves, the form of all the filling timbers may by them be determined. *Du Hamel's Naval Architecture.*

RIBS, *Costæ*, in anatomy, long arched bones, serving to sustain the inner sides of the thorax.

The ribs are twenty-four in number, viz. twelve on each side the twelve vertebræ of the back; they are crooked, and like to the segments of a circle; they grow flat and broad, as they approach to the sternum; but the nearer they are to the vertebræ, they are the rounder and thicker; at which end they have a round head, which, being covered with a cartilage, is received into the sinus in the bodies of the vertebræ; and at the neck of each head, except the two last ribs, there is a small tubercle, which is also received into the sinus of the transverse processes of the same vertebræ. The ribs, thus articulated, make an acute angle with the lower vertebræ. The ribs have each a small canal or sinus, which runs along their under sides, in which lies a nerve, vein, and artery. Their extremities, which are fastened to the sternum, are cartilaginous, and the cartilages make an obtuse angle with the bony part of the ribs: this angle respects the head. The cartilages are harder in women than in men, that they may better bear the weight of their breasts. The ribs are of two sorts; the seven upper ones are called *costæ veræ*, because their cartilaginous ends are received into the sinus of the sternum; the five lower are called *falsæ*, because they are softer and shorter, of which only the first is joined to the extremity of the sternum, the cartilaginous extremities of the rest being tied to one another, and thereby leaving a greater space for the dilation of the stomach and entrails. The last of these false ribs is shorter than all the rest; it is not tied to them, but sometimes to the *musculus obliquus descendens*. If the

the

the ribs had been articulated with the bodies of the vertebræ at right angles, the cavity of the thorax could never have been enlarged in breathing. If each rib had been a rigid bone articulated to the transverse processes of the vertebræ, the sternum could not have been thrust out to that degree that it is now, or the cavity of the thorax could not have increased so much as is requisite in inspiration; for, when the ribs are pulled up by the intercostal muscle, the angles which the cartilages at the sternum make with the bony part of the rib, must be increased, and consequently its substance, or the distance between the sternum and the transverse processes, lengthened. Now because the rib cannot move beyond the transverse process, upon the account of its articulation with it, therefore the sternum must be either thrust to the other side, because of an equal pressure upon the same account there; and therefore it is thrust outwards, or the distance between the sternum and vertebræ is increased. The last ribs which do not reach the sternum, and consequently produce nothing in this action, are not articulated with the transverse processes.

RIBS of a Ship, a figurative expression which implies the timbers. See the article **TIMBER**.

RIBS of a Parrel. See the article **PARREL**.

RICE, *Oryza*, in botany, &c. See the article **ORYZA**.

RICKETS, *Rhachitis*, in medicine, a disorder incident to children, proceeding from an unequal nutrition.

Children are seldom attacked with rickets before they are nine months old, and after they are two years old. It may originally proceed from the disorders of the parents, and may be increased by those of the nurse. It is also promoted by feeding the child with aqueous and mucous substances, crude summer fruits, fish, and too great a quantity of sweet things; by sitting too much, especially in a perforat-chair, with its coats up; by a striking in of the itch, &c.

This disorder is known from a flaccid tumour of the head and face, a flabby loose skin, a swelling of the belly, and a falling away of the rest of the other parts, especially of the muscles; from protuberances of the apophyses of the joints, such as the wrists, ancles, and knees; from the largeness of the jugular veins and arteries, while the rest decrease; from knotty ribs, a narrow breast, and carious teeth, &c.

The cure, according to Boerhaave, is to be attempted with light, nourishing, dry aliment; not fat, but seasoned, and taken often; with little sound drink, such as mild beer, or ale; with a dry warm air, and warm woollen cloathing; with being carried about in the arms, or drawn in a vehicle over the stones, and often shook, swung, and put in motion; with repeated frictions, especially of the belly and spine of the back with warm dry flannel, sprinkled with aromatics; with gentle emetics frequently though prudently repeated; with strengthening purges for several days successively; and with cold bathing, the child being put to sweat between blankets every day, as soon as he comes out of the water.

Particularly for food, the bread should be biscuit, with a little saffron and spices; the flesh should be pigeons, pullets, veal, rabbits, mutton gently roasted, minced and mixed with biscuit, salt, a little parsley, thyme, nutmeg, or the like. He may also eat rice, millet, or pearl-barley, boiled with raisins, to which add a little wine, of which an ounce may be given three or four times a day; as also Brunswic mum and English beer, which in the summer may be mixed with spaw-water. Let the pillow and bed be filled with the following leaves dried in the shade, viz. of malefern, three pounds; of marjoram, baum, and mint, each two handfuls; and of the flowers of melilot, sweet trefoil, elder, and roses, dried in the shade, of each two ounces: reduce them all to powder, and mix them with double the quantity of barley-chaff.

RIDEAU, in fortification, a small elevation of earth, extending itself lengthwise on a plain, serving to cover a camp, or give an advantage to a post.

The word is French, and signifies, literally, a curtain, or cover.

Rideau is also used for a trench, the earth of which is

thrown up on its sides to serve as a parapet for covering the men.

RIDGE, in building, the highest part of the roof, or covering of a house, &c.

RIDGE, in agriculture, a long piece of rising land, between two furrows.

The method of plowing land up into ridges is a particular sort of tillage. The chief use of it consists in the alteration it makes in the degrees of heat and moisture; these being two of the grand requisites of vegetation, and very different degrees of them being requisite to the different sorts of plants. Those plants commonly sown in our fields require a moderate degree of both, not being able to live upon the sides of perpendicular walls in hot countries, nor under the water in cold ones, neither are they amphibious; but they must have a surface of earth, not covered, nor much soaked with water, which deprives them of a proper degree of heat, and causes them to languish. In this case they look weak, and their leaves yellowish. They cease growing, and, in fine, die in a very weak and bad state. The only way to cure the land of giving this disease to plants, is to lay it up in ridges, that the water may fall off, and run into the furrows below, from whence it may be conveyed by drains and ditches into some river, or otherways carried wholly off from the land.

The more any soil is filled with water, the less heat it will have. The two sorts of land most liable to be overglutted with water are hills, the upper stratum of mould in which lies on clay; and, generally, all deep and strong lands. Hills are made wet and spewy by the wet that falls in rain, dews, and mists; and this wet, not being able to sink through the clay, in these soils, runs down between it and the mould; but extending itself through the mould all the way, and making it continually washy. The plowing this sort of land in ridges, made from the higher to the lower part of the field, is of no benefit; for the water will press from below upwards in these ridges, being forced by the addition of fresh supplies above.

There are two methods of draining a hill ground like this. The one is to dig several deep trenches cross-wise, or horizontally on the sides of the hill: let these be nearly filled up with shores, and the surface covered in the common method: the wet will be received into these in all parts, and discharged at the ends; and the plough will go over the stones, without striking through the depth of earth that covers them. Thus, the land will be dried for a time; but, as these channels fill up with earth, between the stones, they become of no use, and the expence of making new ones is very great.

The other way is to plow the land in ridges almost horizontally, and then the furrows between them are so many drains, carrying off the water at their lower ends; if the plough is made to strike a few inches deep into the clay, and the ends of the furrows are no higher than the other parts: every furrow will be a drain to every ridge, and the land of the ridges will be kept dry. If there were no other manner of plowing the ridges on the sides of hills, than there is in the plain lands, this method of having open furrows or drains on declivities would be impracticable; because the plough could not turn up the furrows against the hill and against the ridge also, from the lower side of it. But the easy remedy against this inconvenience is to plow such ridges in pairs, without throwing any earth into the trenches; and then the ridges will be plain at top, and the rain-water will run speedily downwards to the next trench, and thence to the head land; and so out of the field. These trenches will be made, as well as kept always open, by plowing in pairs; and this is abundantly more easy than the way of plowing ridges singly.

Every time of plowing the ridges must be changed as to the pairs; so that the furrow, which had two ridges, or lands, turned towards it one time, must have two turned from it the next time; and this method keeps the surfaces of all the ridges or lands pretty nearly even. This, however, cannot be done on a hill, whose declivity is so great, that the plow is not able to turn a furrow against it; but, in this case, perhaps, it may be

suffi-

sufficient to plow the ridges obliquely enough for the furrows to be turned both ways.

This plowing in an horizontal manner, on hills, is the best of all others; but our farmers are not to be easily brought into it, though they see thin lands of this kind ruined for want of it; their reasons for not doing it, are, that it would prevent the supposed benefit of croses plowing; and that they lose more ground by having more furrows between the ridges, than when they lay their lands flat, where the lands are made much larger than the round ridges can conveniently be.

RIDERS, in *Ship-building*, strong timbers fayed on the inside of the ship, and reaching from the keel upwards to the beams of the orlop, or lower deck, and sometimes higher. They are usually fixed in the middle of the ship when she is considerably weakened by age, or lying often on the ground. Sometimes it is necessary to fix two riders, or riding timbers, to give the ship a greater support; and then, one is placed before the mid-ship beam, and the other abaft it. They are termed riders from being placed immediately over the floor-timbers, to which they are strongly bolted.

RIDGES of a Horse's Mouth, are wrinkles or risings of the flesh, in the roof of the mouth, running across from one side of the jaw to the other, with interjacent furrows.

RIDING, in the sea language, the situation of a ship which lies at anchor in a road, bay, or haven.

There are various positions of riding, according to the circumstances of the tide, wind, or current; as riding athwart, riding between wind and tide, &c.

Riding athwart, is when the ship lies nearly at right angles with the current. This is occasioned by the great force of the wind, which acts in opposition to the tide, and over-balances it by as much as the ship is moved across its stream.

Riding between wind and tide, is the situation in which a ship lies, when the one counter-acts the other so as to diminish its effort considerably, and occasion the ship to lie as it were balanced between them.

Riding easy, is the state of a ship which does not strain hard upon her cables, by pitching deep into the water, and rising with a sudden jerk, so as to dislodge the anchor, or break the cable.

Riding hard, the state of labouring violently at anchor in a road which is exposed to the force of the wind and the swell of the sea, so as to endanger the cables and anchors, besides straining the hull to a great degree. A ship which rolls at her anchors, always rides easy; whereas one that pitches usually rides very hard.

RIGADOON, a gay and brisk dance, borrowed originally from Provence in France, and performed in figure, by a man and a woman.

RIGGING, amongst seamen, a term which comprehends all the ropes, either to secure the masts, or manage the sails and yards.

Rigging is usually divided into two parts, viz. the standing, and the running.

The standing rigging denotes, in general, all that which is employed to fasten and sustain the several masts of a ship. Such are the shrouds, stays, and back-stays. The shrouds sustain the masts on each side, the stays support them from before, and the back-stays from behind. Back-stays however are only used to the top-masts; their intent being answered on the lower-masts by the aftmost shrouds.

The running rigging implies all the ropes which are employed to dilate, contract, or change the disposition of the sails. They are called running because they move through a number of blocks and pulleys, artfully disposed amongst the yards and masts. The other rigging is termed standing, because it is always drawn tight, and is never removed but when the ship is either partially, or wholly unrigged. See **SHROUD**, **STAY**, and **BACK-STAY**.

The principal articles of the running rigging are, the haliards, to hoist up the sails; the sheets, to extend their lower corners; the braces, to wheel them about on the masts; and the brails, to draw them up together when they are to be reduced or furled. See **BRACE**, **BRAIL**, **FURL**, **HALIARD**, and **SHEET**.

A mast is rigged thus: first a collar, or ring of rope, is

put over it, to prevent the rigging from being cut or chafed; then the runner pendants; a pair of shrouds on the starboard side; a pair on the larboard; and so on alternately till all the shrouds are fixed; after which the stays are placed over all. The shrouds first placed on the mast-head are the farthest forward, and the last farthest aft. See **PENDANT**.

The rigging of a yard is also begun by a sort of collar; next the horses; the braces; and lastly the lifts.

RIGGING-OUT, thrusting out any boom to extend the foot of a sail, as the jib-boom, which is run out from the bowsprit; the driver-boom, which projects over the ship's side; and the studding sail booms, which are thrust out from the several yard-arms.

RIGHT, in geometry, signifies the same with straight: thus, a straight line is called a right one. See **LINE**.

As for right angle, right ascension, right cone, right descension, right line, right sphere, &c. they are explained under the articles **ANGLE**, **ASCENSION**, &c.

RIGHTING of a Ship, amongst seamen, the act of raising or erecting her after she had inclined to one side, on a careen or otherwise.

RIGHTING the Helm, placing it amid-ships, so as to make the ship continue in the course to which her stem is directed by the former impulse of the helm.

RIGIDITY, in philosophy, a brittle hardness; or that species of hardness supposed to arise from the mutual indentation of the component particles within one another.

RIGOR, in medicine, a convulsive shuddering, from severe cold, an ague-fit, or other disorder.

RIM of the Top, in the sea-language, the outer-edge of it, through which the plates of the top-mast shrouds pass.

RIME, or **RHYME**. See **RHYME**.

RIND, the coat or skin of any fruit, &c. It is also used for the inner bark of trees, or that soft, whitish, juicy substance adhering immediately to the wood.

RING, an ornament of gold, silver, &c. made of a circular form, and generally worn on the finger.

RING-BORE, in farriery, a hard callous substance, growing in the paster of a horse, above the coronet: it is thus called from its growing quite round like a ring.

RING-WORM, in medicine, the same with the serpigo. See the article **SERPIGO**.

Saturn's RING, in astronomy. See **SATURN**.

RING-BOLT, in ship-building, a strong ring of iron with a bolt in it, which is driven into the sides or decks of a ship, to which the ring is firmly confined. These are principally employed to fasten or secure the moveables on the deck at sea, particularly the cannon, and boats.

RING-ROPE, a short rope, occasionally fastened to the ring-bolts, to secure the cable, when it is to be gradually slackened or veered out in tempestuous weather.

RING-TAIL, a small flying-sail, extended occasionally in the after-part of some small ships.

RIOT, in law, the forcibly doing of an unlawful thing, of a private nature, by three or more persons assembled together, for that purpose.

By a late act of parliament, a riot was made felony, if the rioters did not disperse after reading the proclamation for that purpose.

RIPENERS, in medicine, a kind of topical medicines, which promote suppuration.

RIPPLING, amongst sailors, a short broken interrupted current, which produces a murmuring noise to a considerable distance.

RITE, *Ritus*, among divines, denotes the particular manner of celebrating divine service, in this or that country. See the article **RITUAL**.

RITORNELLO, or **REPEAT**, in music, the burden of a song, or the repetition of the first or other verses of a song at the end of each stanza or couplet.

Custom has extended the use of the word to all symphonies played before the voices begin; and which serve by way of prelude to what follows.

In the partitions of the score of the Italian music, we frequently find the ritornellos signified by the words *si su-*

ona, to shew that the organ, spinnet, harpsichord, or the like, are to repeat some bars of what the voice has been singing.

RITUAL, a book directing the order and manner to be observed in celebrating religious ceremonies, and performing divine service in a particular church, diocese, order, or the like.

RIVER, *Fluvius*, or *Flumen*, a current, or stream of fresh water flowing in a bed or channel, from its source into the sea.

The great, as well as the middle-sized rivers, proceed either from a confluence of brooks and rivulets, or from lakes; but no river of considerable magnitude flows from one spring, or one lake, but is augmented by the accession of others. Thus the Wolga receives above two hundred rivers and brooks before it discharges itself into the Caspian Sea; and the Danube receives no less, before it enters the Euxine Sea. Some rivers are much augmented by frequent rains, or melted snow. In the country of Peru, and Chili, there are small rivers, that only flow in the day; because they are only fed by the snow upon the mountains of the Andes, which is then melted by the heat of the sun. There are also several rivers upon both sides the extreme parts of Africa, and in India, which for the same reason are greater by day than by night. The rivers also in these places are almost dried up in summer, but swell and overflow their banks in winter, or in the wet season. Thus the Wolga in May and June is filled with water, and overflows its shelves and islands, though at other times of the year it is so shallow, as scarcely to afford a passage for loaded ships. The Nile, the Ganges, the Indus, &c. are so much swelled with rain or melted snow, that they overflow their banks; and these deluges happen at different times of the year, because they proceed from various causes. Those that are swelled with rain, are generally highest in winter, because it is usually then more frequent than at other times of the year; but if they proceed from snow, which in some places is melted in the spring, in others, in summer, or between both, the deluges of the rivers happen accordingly. Again, some rivers hide themselves under-ground, and rise up in other places, as if they were new rivers. Thus the Tigris meeting with mount Taurus, runs under it, and flows out at the other side of the mountain: also, after it has run through the lake Tospia, it again emerges, and being carried about eighteen miles under ground, breaks out again, &c.

The channels of rivers, except such as were formed at the creation, Varenus thinks, are artificial. His reasons are, that, when a new spring breaks out, the water does not make itself a channel, but spreads over the adjacent land; so that men were necessitated to cut a channel for it, to secure their grounds. He adds, that a great number of channels of rivers are certainly known from history to have been dug by men.

The water of most rivers flow impregnated with particles of metals, minerals, &c. Thus some rivers bring sands intermixed with grains of gold; as in Japan, Peru, and Mexico, Africa, Cuba, &c. particularly in Guinea is a river, where the negroes separate the gold dust from the sand, and sell it to the Europeans who traffic thither for that very purpose. The Rhine in many places is said to bring a gold mud. As to rivers that bring grains of silver, iron, copper, lead, &c. we find no mention of them in authors; though, doubtless, there are many, and it may be to them that mineral waters owe many of their medicinal virtues.

Theory of the Motion of RIVERS. The running of rivers is upon the same principle as the descent of bodies on inclined planes; for water no more than a solid can move on an horizontal plane, the re-action of such a plane being equal and contrary to gravity, entirely destroys it, and leaves the body at rest: here we speak of a plane of small extent, and such as coincides with the curved surface of the earth. But if we consider a large extent or long course of water, then we shall find that such water can never be at rest, but when the bottom of a channel coincides every where with the curved surface of the earth.

Let A D F (plate CX. fig. 1.) be the curved surface of the earth, C its centre, C D, C E two right lines

drawn from thence, and E G a tangent to the earth in the point D. Then it is plain if B D were a channel of water, the water could not run, or move, because they are every where at an equal distance from the center C, and therefore equally affected by gravity. But if there be any place above the surface of the earth, as E, where water can be found, 'tis evident that water can descend in a channel to any part of the earth's surface between B and D, because every point in the line E D is nearer to the center of the earth, and therefore below the point or place E; and its velocity will be so much the greater as it tends to a point nearer B, and slowest of all, when it moves in the direction of the tangent E D.

Hence it appears that the source E of all rivers and streams must be more than a semi-diameter of the earth C B distant from the center C. And since all great rivers run to the sea or ocean where they disembogue their waters at the point D, the line D C is a semidiameter, and = 4000 miles nearly. Also the course of all long rivers being in the direction of the tangent at the point D, if they were represented by the tangent-line E G, then the height of the source E above the common surface of the earth at B would be easily found. Thus, suppose E D were the river Niger in Africa, whose source is more than 3000 miles from the sea; but put E D = 3000, and since C D = 4000, we shall have C E = 5000, and C E - C B = 1000 = B E = the height of the source. But since we know of no mountains above three or four miles high, it is plain the river Niger, and all such long rivers, are so far from moving in a tangent, that their course must be very nearly of the same curvature with the earth's surface, and insensibly distant from it.

Since bodies move on planes ever so little inclined, except so far as they are prevented by friction, and since the friction of the particles of water among themselves is inconsiderable, it follows that the water situated on a plane ever so little inclined, will commence a motion: and if the plane be considerably inclined, and the quantity of water great, its velocity will be proportional, and its momentum such as will soon begin to wear away the earth, and create itself a course or channel to glide in. In rivers that are made, it is usual to allow the fall of one foot in 300.

If we allow the same declivity to rivers which make their own way, then we find their height at their source above the common surface of the sea, as in example of the Niger thus: As 300 : 1 :: 5280 : $\frac{5280}{300}$ = the height at one mile, or 5280 feet. Then again say, as 1 : — $\frac{5280}{300}$

:: 3000 : $\frac{5280 \times 3000}{300}$ = 5280 × 10 = 10 miles.

From whence it is evident, that the continents and islands ought to be much above the surface of the sea, to give a necessary descent and course to the waters through them.

Let A B C D (fig. 2.) be the section of a reservoir, and B C I K the section of a canal of water supplied from thence, and A B N the horizontal line. Now, since the particles of water are governed by the common laws of gravity; the velocity of a particle at any part of the bottom of the canal, as F or H, will be the same as it would acquire by falling through the perpendicular altitude O F or L H, that is, as $\sqrt{O F}$ to $\sqrt{L H}$. Hence the velocity of the stream is accelerated.

For the same reason the velocity of a particle at the bottom of the stream H is to the velocity of a particle at the top G, as $\sqrt{L H}$ to $\sqrt{M G}$; consequently the stream moves with a greater celerity at bottom than at top.

The quantity of the water which passes through the section of the stream H G, is the same that passes through the section of the reservoir B C in the same time. The same may be said of any other section F E; therefore the quantity of water, passing by any two sections of the stream F E and G H, in the same time, is the same.

Since there runs the same quantity of water by G H as by F E in the same time; and since the velocity at G H is greater than at F E; and, lastly, since the breadth of the canal is supposed to be every-where the same; therefore it follows, that the depth G H must be less than

Fig. 1. Motion of Rivers.

the depth F E, and so the depth of the stream must continually decrease as it runs.

As the stream proceeds, the depth H G decreasing, the lines M G and L H will approach nearer to an equality; and therefore the different velocities of the water at top and bottom will approach much faster to an equality, as being proportionate to the square roots of those lines. This approach to an equality is much farther promoted, by the upper parts being continually accelerated by the lower, and the lower parts retarded continually by the slower motion of the waters above, and pressing upon them.

Since the difference of the descending velocities is greatest near the head of the stream, the waters will there fall or descend with the greatest impetuosity, or cause the loudest noise. But in the course of rivers, the accelerated velocity is quickly reduced to an equable or uniform velocity, by the resistance it meets with from the bottom and sides of the channel, which resistance will be as the squares of the velocities, and therefore soon become so great as to equal the accelerating force, and be communicated to the middle part of the stream, causing the whole to move uniformly. Hence, in rivers, the motion of the water is slowest at the sides and bottom of the channel, because there the resistance begins, which is afterwards communicated to all the other parts; and in different parts of the same river, the uniform velocity is greatest, where the bottom of the channel has the greatest inclination, or declivity, because the relative gravity of the moving particles is here greatest. Again, in those parts of the river where the velocity of the stream is least, the depth of the water is greatest, and *vice versa*, because equal quantities pass through unequal sections of the river in the same time. Hence also it follows, that the momentum of running water must be every where the same, or a given quantity.

RIVULET, a diminutive of river. See RIVER.

ROACH, in ichthyology, a species of cyprinus, with the iris and belly-fins usually red; it is generally, when full grown, nine inches long, but it sometimes grows considerably larger.

ROACHING of Alum, is the last process in making alum, which being sufficiently washed in a cistern of strong alum-water, is put into large pans, and a quantity of water added to it; and then being set over the fire to melt, and boil a little, it is scooped into a great cask, where it is suffered to stand and crystallize, and is what they call roach, roached, or rock alum. See ALUM.

ROAD, an open way, or public passage, forming a communication between one place and another.

ROASTING, in metallurgy, the separation of volatile bodies from those which are more fixed, by the combined action of air, and fire; and is generally the first process in the separation of metals from their ores: it differs from sublimation only in this, that in this operation the volatile parts are dissipated, when resolved into vapours; whereas in that, they are preserved. See SUBLIMATION.

Sulphur and arsenic are in this manner collected, and preserved, in the roasting of many ores; and sublimation made, as it were, occasionally in the process.

The separation of the volatile parts of bodies from the more fixed is, however, in many cases very difficult, and much nicety is required in the conducting this operation; this is the case, for instance, when the whole compound body melts in almost the same degree of fire that is necessary to raise, and dissipate the volatile parts in the air; in such cases, care must be taken, first previously to pound a little the body to be roasted, that its surface contiguous to the air may be increased in extent. A gentle fire is also necessary on such occasions, and a very free access of the air, which is the vehicle of these vapours. When the body in the roasting grows on these occasions into large lumps or clots, the surface of it must be restored to the necessary extent, by repeated poundings; for it is necessary above all things, that the matter be kept extended and recent, and never collected into a heap.

Roasting, as commonly practised, is subject to many inconveniences, which may be most of them easily remedied, and the whole business reduced to a few easy rules.

1. The roasting of ores should be always performed,

without addition, when the ores are rich, or of itself merely of a metallic nature. But the additions of quicklime, pot-ashes, iron-filings, and the like, are necessary, when arsenical, antimonial and sulphureous matters are found to be mixed with the ores. 2. The fire is to be so regulated from the first, that only the lighter or more volatile sulphureous or arsenic fumes may fly off, otherwise the more metallic part would likewise go, and without some contrivance to catch it would be lost. The ore must, however, always feel the force of an open flame, otherwise the sulphur, arsenic, &c. will never be thoroughly dislodged. 3. The more these immature substances abound in ore, the gentler the fire should be at first; and when the greater part of the sulphureous matter is thus exhaled, the fire is then to be quickened. 4. Where such additions are used, as are not metalline, as lime, mud, pot-ash, &c. they ought always to be separated afterwards from the matter before the fusion, by washing.

ROB, in pharmacy, the juices of fruits purified and inspissated till it is of the consistence of honey.

ROBBERY, in law, a felonious taking away another man's goods from his person, presence, or estate, by putting him in fear.

ROBERVALLIAN LINES, certain lines used for the transmutation of figures, and so called from their inventor M. de Roberval.

ROBORANTS, *roborantia*, in pharmacy, medicines which strengthen the parts, and give new vigour to the constitution. See the article STRENGTHENERS.

ROCKET, in pyrotechny, an artificial fire-work, consisting of a cylindrical case of paper, filled with a composition of certain combustible ingredients; which, being tied to a stick, mounts into the air, to a considerable height, and there bursts.

The rocket, above defined, is properly the sky-rocket; the method of making which, is this. 1. A concave cylindrical mould, A B, plate CX. fig. 3. is turned of hard-wood, with a base B D, and a capital H C, usually adorned with suitable mouldings. This cylinder must be open at both ends, and its dimensions, for rockets of various sizes, as in the following article. When large, it is sometimes also made of brass or tin; and when small, of bone. 2. Of the same matter with the cylinder, is prepared a quadra, or foot, M E; in the middle of which is turned a hemisphere G O, considerably less than the cavity of the cylinder; making the cap or head of another cylinder I K, and reaching up within the case, where it is kept steady by a pin L M.

Authors do not agree about the proportions.—Simionowitz describes those that follow: if the diameter of the aperture H N be equal to that of a leaden ball of a pound, or at most two pounds weight; the height of the cylinder, with the base and capital H C, to be seven diameters, and the height of the quadra F E, $1\frac{1}{4}$. The altitude of the cylinder K I, 1. The diameter H N, $\frac{1}{2}$. The diameter of the hemisphere G, $\frac{2}{3}$. The height of the capital A C, 1. The same author adds, that he finds by abundant experience, that if the diameter of the aperture be divided into 100 parts, according to the different weight of the leaden balls, to whose diameter it is equal, the following numbers, being multiplied by 7, give the height H E.

Weight of leaden ball.	Subseptuple of altitude H E.

The mould being ready, a wooden cylinder or mould A B (*fig. 4.*) is provided, whose diameter is $\frac{1}{3}$ of the aperture of the frame, and its length equal to the height of the same; to which is fixed a haft or hilt A D. About this mould is a thick strong paper rolled, till such time as it fills the cavity of the frame. This done, where the haft is joined to the cylinder, as at A, it is choaked, i. e. firmly bound round with fine pack-thread, so as to constringe or straighten the cavity thereof. The part thus choaked or bound up F G, to be equal to the hemisphere G O.

The case is now taken off the mould, and put into the cavity of the frame, the choak G F upon the hemisphere; and in this disposition is filled with a composition described in the following table, rammed strongly in by means of a wooden cylinder, or rammer fitting the cavity, and a mallet.

When filled, a paper-cap of a conical form is glued over the end of the case filled last; and the space left at top filled with whole gunpowder, to the height of about one diameter; then the rocket bound, or choaked in E, as before in G. Lastly, the rocket is bored, as is represented in A L, care being taken to do it in the middle. Some, indeed, bore the rocket, as they fill it, by thrusting a long, sharp spike through the lower basis, and drawing it out again, when the rocket is full; but it is best not to bore till the rocket be used.

The boring is to go two-thirds of the height of the rocket, abating one diameter of the cavity. The diameter of the bore in G is to be $\frac{1}{4}$ of the diameter of the cylinder; and in L $\frac{1}{8}$ of the lower diameter.

To make the rocket mount straight up, it is tied fast to the end of a long slender stick, M D, eight times as long as the rocket, in such manner, as that, when poised on the finger near the touch-hole F, the stick (which is usually made biggest at this end, and sloping gently to the other) may preponderate, though very little. The rocket thus equipped, is hung at freedom, and lighted with port-fire.

Note, Some, instead of a stick to make the rocket mount, furnish it with two wings, as M N, which have the same effect; and, instead of paper, some make the cases of wood covered with leather; others of a thin iron plate. And some, instead of a wooden stick, use an iron-wire, with a plummet at the end of it.

The composition with which rockets are filled, consists of the following ingredients, viz. salt-petre, charcoal, and sulphur, all well ground; but the proportions of these are various, for rockets of various sizes; as in the following table. Noting, that in small rockets, gunpowder-dust is added.

Compositions of ROCKETS of various sizes.

Note, several rockets being disposed round the circumference of a wheel, whether circular or polygonous, the head of the one is applied to the tail of another, and the wheel put in motion; as one rocket is spent, another will take fire; and the wheel be continued in its rotation.

As an additional ornament to rockets, it is usual to furnish them either with stars or with serpents, or sparks,

which take fire when the rocket bursts; and sometimes little rockets are inclosed in great ones, to take fire when the large one is at its greatest height.

To make Stars for ROCKETS. Mix three pounds of salt-petre with eleven ounces of sulphur, three ounces of beaten gunpowder, and ten of antimony. Moisten the mass with gum-water, and form them into little balls of the size of filberds; drying them well, either in the sun or an oven. When dry, inclose a number of them in the conical cap of the rocket.

Theory of the Flight of Sky-ROCKETS. Mariotte takes the rise of rockets to be owing to the impulse or resistance of the air against the flame: Dr. Desaguliers accounts for it otherwise.

Conceive the rocket to have no vent at the choak, and to be set on fire in the conical bore; the consequence will be, either that the rocket would burst in the weakest place, or if all its parts were equally strong, and able to sustain the impulse of the flame, the rocket would burn out immovable. Now, as the force of the flame is equable, suppose its action downwards, or that upwards, sufficient to lift forty pounds. As these forces are equal, but their directions contrary, they will destroy each other's action.

Imagine, then, the rocket opened at the choak; by this means the action of the flame downwards is taken away, and there remains a force equal to forty pounds acting upwards, to carry up the rocket and the stick it is tied to. Accordingly, we find that if the composition of the rocket be very weak, so as not to give an impulse greater than the weight of the rocket and stick, it does not rise at all; or if the composition be slow, so that a small part of it only kindles at first, the rocket will not rise.

The stick serves to keep it perpendicular; for if the rocket should begin to stumble, moving round a point in the choak, as being the common center of gravity of rocket and stick, there would be so much friction against the air, by the stick between the center and the point, and the point would beat against the air with so much velocity, that the reaction of the medium would restore it to its perpendicularity.

When the composition is burnt out, and the impulse upwards is ceased, the common center of gravity is brought lower towards the middle of the stick; by which means the velocity of the point of the stick is decreased, and that of the point of the rocket increased; so that the whole will tumble down, with the rocket-end foremost.

All the while the rocket burns, the common center of gravity is shifting and getting downwards, and still the faster and the lower, as the stick is the lighter; so that it sometimes begins to tumble before it be burnt out; but when the stick is a little too heavy, the weight of the rocket bearing a less proportion to that of the stick, the common center of gravity will not get so low, but that the rocket will rise straight, though not so fast.

Method of making a Water-ROCKET. Make a rocket after the usual manner, excepting the number of choaks. Let its diameter be equal to that of a leaden-ball, of two or three inches diameter, and let it be bored to a third part of its height. Inclose the rocket in a hollow paper cylinder, which smear over with melted pitch or wax, that it may resist the moisture.

Note, the weight of the rocket is to be so proportioned to that of the water, that the whole cylinder may be emerged. Some, instead of a cylinder, use a truncated cone, or even a spheroid; and some hang a weight to the end at which it is lighted.

ROD, a wand, or long slender staff.

ROD is also used for a land measure of sixteen feet and a half: the same with perch and pole.

ROD, in gauging. See GAUGING.

Black-ROD, a staff carried by the king's gentleman-usher, as a badge of his office; this rod or staff is black, and has a lion in gold on its top.

ROE, the spawn or seed of fish. That of the male-fishes is usually distinguished by the name of soft roe, or milt, and that of the female, by hard roe, or spawn.

ROGATION, in the Roman jurisprudence, a demand made by the consuls or tribunes of the Roman people, when a law was proposed to be passed. Rogatio is also

also used for the decree itself made in consequence of the people's giving their assent to this demand, to distinguish it from a *senatus consultum*, or decree of the senate.

ROGATION-WEEK, the week immediately preceding Whitsunday, so called from the three fasts therein on Monday, Tuesday, and Wednesday, which are also called rogations, or rogation-days, from the extraordinary prayers and supplications at this time offered to God by devout Christians, to appease his anger and deprecate his judgments.

ROGUE, in law, an idle sturdy beggar; who by ancient statutes is for the first offence called a rogue of the first degree, and punished by whipping, and boring through the gristle of the right ear with a hot iron; and for the second offence, is termed a rogue of the second degree, and if above eighteen years of age, ordered to be executed as a felon.

ROGUES-YARN, in sea-affairs, a yarn or thread in all cordage made for the king's service, by which such cordage may be easily distinguished from any other, as the rogues-yarn is twisted contrary to all the other. The use of this precaution is to prevent or discover embezzlement of the cables, hawsers, &c. by the boatswain, who is charged with them.

ROLL, in manufactories, something wound and folded up in a cylindrical form.

ROLL, in law, signifies a schedule or parchment which may be rolled up by the hand into the form of a pipe.

Mustel-ROLL, that in which are entered the soldiers of every troop, company, regiment, &c.

Rider-ROLL, a schedule of parchment frequently sewed or added to some part of a roll or record.

ROLLS of Parliament, are the manuscript registers, or rolls of the proceedings of our ancient parliaments, which before the invention of printing were all engrossed on parchment, and proclaimed openly in every county.

ROLL, or **ROLLER**, is also a piece of wood, iron, brass, &c. of a cylindrical form, used in the construction of several machines, and in several works and manufactures.

ROLLER, in surgery, a long and broad bandage, usually of linen cloth, rolled round any part of the body, to keep it in, or dispose it to a state of health.

ROLLING-PRESS Printing. See the article **PRINTING**.

ROLLING, in naval affairs, the motion of a ship rocking from one side to the other, as produced by the agitation of the waves.

When a ship rolls heavily at sea, it exposes the mast continually to the danger of being carried away. It is generally occasioned by the ship having too great a quantity of heavy ballast near the keel, which makes the vessel very stiff. See the article **TRIM**.

The rolling motion of a ship appears to begin from a center at the keel, where the garboard strake or plank is let in; if so, there is a motion below it to the depth of the keel, as well as the motion aloft; although the keel has but little motion comparatively with the motion above: and the greater will that motion be in proportion to its distance, even to the spindle at the top-mast-head, which makes the radius, and consequently the circle greater. The keel being intire, as the body of the vessel moves one way, the lower part of the keel moves contrariwise; and the deeper it is, the larger is the body or circle of water moved thereby. Is it not therefore demonstrable, that the greater the body of water is, which opposes the motion of the keel, the greater is the opposition? For if the keel had no motion from the center before-mentioned, or from the step of the main-mast, which perhaps is more properly the center of motion, there would be no motion above it.

ROLLING-TACKLE, a tackle hooked to the weather-yard-arm, to confine the yard to leeward, and prevent it from rubbing the mast, and galling it by the agitation of the ship.

ROMAN, in general, something belonging to the city of Rome.

King of the ROMANS, in modern history, is a prince elected to be successor to the reigning emperor of Germany.

ROMAN Order, in architecture, the same with the Composite order. See the articles **ORDER** and **COMPOSITE**.

ROMANCE, in matters of literature, a fabulous relation of certain adventures, designed for the entertainment and instruction of the readers.

ROMPEE, or **ROMPU**, in heraldry, is applied to ordinaries that are represented as broken, and to chevrons, bends, or the like, whose upper points are cut off.

ROOD, a quantity of land equal to forty square perches, or the fourth part of an acre.

ROOF, in architecture, the uppermost part of a building.

The roof contains the timber-work, and its covering of slate, tile, lead, &c. though carpenters usually restrain the word to the timber-work only.

The form of roofs is various; sometimes it is pointed, in which case the most beautiful proportion is to have its profile an equilateral triangle: sometimes it is square, that is, the pitch or angle of the ridge is a right angle, which therefore is a mean proportion between the pointed and flat roof, which last is in the same proportion as a triangular pediment: this is chiefly used in Italy, and the hot countries, where there is but little snow. Sometimes roofs are made in the pinnacle form: sometimes they have a double ridge; and sometimes they are mutilated, that is, consist of a true and a false roof, which is laid over the former: sometimes again they are in the form of a platform, as most of the eastern buildings are; and sometimes they are truncated, that is, instead of terminating in a ridge, the roof is cut square off at a certain height, covered with a terrace, and encompassed with a balustrade; and sometimes, again, a roof is made in the manner of a dome. When the walls have been raised to their designed height, the vaults made, the joists laid, the stairs, &c. brought up, then the roof is to be raised, which embracing every part of the building, and with its weight equally pressing upon the walls, is a band to all the work; and besides, defends the inhabitants from rain or snow, the burning heat of the sun, and the moisture of the night, and is of no small advantage to the building, in casting off the rain water from the walls.

ROOK, in ornithology, a species of the wholly black corvus. See **CORVUS**.

ROOT, *Radix*, among botanists, denotes that part of a plant which imbibes the nutritious juices of the earth, and transmits them to the other parts.

The roots of plants are distinguished, according to their different forms, into bulbose, fibrose, granulose, grumose, tuberose, and tap roots.

As to the gathering and preserving roots for medicinal uses, the Edinburgh Dispensatory directs that the annual roots be taken up before they shoot out stems or flowers; the biennial ones, for the most part, in the autumn of the first year; and the perennial ones when the leaves begin to fall, and therefore generally in autumn: then being cleansed by washing, and freed from the withered and decayed fibres, they are to be hung in a shady place pervious to the air, till they are moderately dry: the thicker roots should be slit lengthwise; or they may be cut transversely into thin pieces, and the pith taken out.

ROOT-GRAFTING, in gardening. See the article **GRAFTING**.

ROOT, in mathematics, implies a quantity considered as the basis or foundation of a higher power; or one which being multiplied into itself any number of times, produces a square, cubic, biquadratic, &c. quantity; called the second, third, fourth, &c. power of the root, or quantity, so multiplied into itself. Thus a is the square root of $a \times a$, or a^2 ; and 4 the square root of $4 \times 4 = 16$. Again, a is the cube-root of $a \times a \times a = a^3$; and 3 the cube-root of $3 \times 3 \times 3 = 27$: and so on. See **EXTRACTION**.

Roots, *Radices*, in grammar, are the primitive words of a language, whence the others are formed or derived.

ROPE, hemp, hair, &c. spun out into a thick yarn, and then several strings of this yarn twisted together by means of a wheel. When made very small, it is called a cord, and when very thick, a cable.

ROPE, a general name given to all the different kinds of rope in a ship. See **RIGGING**, **CABLE**, **HAUSER**, **TOW-LINE**, **WARP**, &c.

ROPE-BANDS, a small cord, in length about three or four times the circumference of the yard. They are inserted through eye-lid holes for the whole length of the upper-edge of the square sails, and are used to fasten the head of the sail to the yard.

ROPE-YARN, a thread or twisted line of hemp, which is the first and simplest part of a rope. A number of these are twisted together to form a strand, in proportion to the size of the rope, whereof the strand makes a part. Three strands are then twisted into one another, which completes the process of ordinary rope-making. But cables, hausers, and other ground-tackling, are composed of three strands, each of which is formed by three lesser ones.

ROSACEOUS, among botanists, an appellation given to such flowers, as are composed of several petals or leaves, disposed in a sort of circular form, like those of the rose: such are the flowers of the piony, crowfoot, cinquefoil, &c. In this sort of flowers the disposition only of the leaves is regarded, their number being of no consequence. It is very seldom that the number is two or four, except in the circæa and onagra. The most frequent number of leaves in these flowers is five, and such as have four differ from the cruciform flowers, not only in their disposition, but in this, that the number is in the same species indeterminately, four, five, or six, as is the case in the clematis, the capers, and the species of rue, whereas in the cruciform ones it is ever constant. See **BOTANY**.

ROSARY, among the Roman-Catholics, the same with chaplet.

ROSE, *Rosa*, in botany, a genus of plants, the flower of which is composed of five petals, obversely cordated, and arranged in a circular form: the fruit is formed of the fleshy base of the cup, which is of a turbinated figure, coloured, soft, containing only one cell drawn together at the neck, and coronated with some irregular laciniae; the seeds are numerous, oblong, and hairy.

The wild briar, with beautiful pinnated leaves, a white or pale red flower, and the common hip for its fruit, is that above described: and, indeed, all the beautiful roses in our gardens, are only varieties of this species, principally owing to culture; the red, the damask, the white, the variegated, &c. roses, being all produced from this original species.

The flowers of the red rose are astringent, those of the damask-rose purgative, and the fruit of the wild-rose pectoral. The rose-water of the shops, distilled from the flowers of the damask-rose, has been celebrated for many virtues; but its fragrant smell is the only quality now regarded in it. There is also a syrup, made either from the juice, or infusion of the fresh flowers of damask-roses.

ROSE, in architecture, an ornament cut in the form of a rose, chiefly used in corniches, friezes, vaults of churches, &c. and particularly in the middle of each face in the Corinthian abacus.

ROSE-NOBLE, an ancient English gold-coin, first struck in the reign of Edward III. It was formerly current at 6s. 8d. and so called because stamped with a rose.

ROSE-WOOD, *Rhodum*, in the materia medica. See **RHODIUM**.

ROSEMARY, in botany, a large shrubby plant, clothed with long narrow stiff leaves, set in pairs, of a dark green colour above, and hoary underneath; producing pale bluish labiated flowers, which stand in clusters round the stalk in the bosoms of the leaves. It is a native of the southern parts of Europe, common in our gardens, and seems to grow larger and more woody in this than in most other countries. It flowers in April and May, and sometimes again about the end of August.

Rosemary is a warm pungent aromatic; particularly useful in phlegmatic habits, and debilities of the nervous system; of the same general nature with lavender, but with more of a camphorated kind of pungency, and of a stronger, and to most people less grateful, smell. The

tender tops are the strongest both in smell and taste, and next to these the cups of the flowers; which last, though somewhat weaker than the leaves or tops, are nevertheless the most pleasant, and hence are generally preferred: it is chiefly, if not wholly, in the cup, that the active matter of the flower resides; for the bluish petalum, carefully separated, has very little smell or taste. The fragrance of these flowers is greatly diminished, or in great measure destroyed, by bruising or beating; and hence the officinal conserve, made by beating them with thrice their weight of sugar, has very little of the flavour of the rosemary.

The leaves and tops of rosemary give out their virtues completely to rectified spirit, but only partially to water: the spirituous tinctures are of a yellowish green colour, the aqueous of a dark greenish brown. Distilled with water, they yield a thin, light, pale-coloured essential oil, inclining a little to a yellowish or greenish, of great fragrancy, though not quite so agreeable as the rosemary itself: from one hundred pounds of the herb in flower were obtained eight ounces of oil: the decoction, thus divested of the aromatic part of the plant, yields on being inspissated an unpleasant weakly bitterish extract. Rectified spirit likewise, distilled from rosemary leaves, becomes considerably impregnated with their fragrance, leaving however in the extract the greatest share both of their flavour and pungency. The active matter of the flowers is somewhat more volatile than that of the leaves, greatest part of it arising with spirit. The Hungary water, used as a perfume, and sometimes medicinally in nervous complaints, and which is said to have received its name from its being first made public by an empress of that nation, who was cured by its continued use of a paralytic disorder, is a strong spirit distilled from fresh rosemary flowers: the college of Edinburgh directs a gallon of rectified spirit to be drawn over in the heat of a water-bath from two pounds of the flowers as soon as gathered: that of London takes the tops, and a spirit not quite so strong; putting a gallon of proof-spirit to a pound and a half of the fresh tops, and drawing off in the heat of a water-bath five pints. The Hungary water brought from France is more fragrant than such as is generally prepared among us.

ROS-SOLIS, **SUN-DEW**, an agreeable spirituous liquor, composed of burnt brandy, sugar, cinnamon, and milk-water; and sometimes perfumed with a little musk: it is so called, as being at first prepared wholly of the juice of the plant *ros-solis*, or *drosera*.

ROSTRA, in antiquity, a part of the Roman forum, wherein orations, pleadings, funeral harangues, &c. were delivered.

ROSTRUM, in chemistry, implies the nose or beak of the common alembic, which conveys the liquor distilled into its receiver.

ROSYCRUCIANS, **ROSICRUCIANS**, or *Brothers of the Rosy Cross*, a name assumed by a sect or cabal of hermetical philosophers, who appeared, or at least were first taken notice of, in Germany, in the beginning of the sixteenth century. They pretended to be masters of all sciences, and to have many important secrets, particularly that of the philosopher's stone.

ROT, a disease incident to sheep, arising from wet seasons, and too moist pasture.

It is a very hard thing to prevent the rot, if the year prove very wet, especially in May and June. Salt-marshes, and lands where broom grows, are the best places of preservation for them. Sheep are sometimes all cleared of the rot, when not too far gone with it, only by removing them into broom-fields. Scurvy-grass, mustard, parsley, and thyme, are also good for the prevention of it.

Some propose the giving sheep half a handful of bay-salt every month or oftener; and there is great probability that this may be of service: but the rational way of attacking all disorders in cattle, is by considering what are the causes of them. It will appear upon enquiry, that wet seasons are the general occasions of the rot in sheep, and therefore it would be advisable for the owners, when such seasons come on, to remove those animals into the driest pastures they can, and then to feed them principally with dry sweet hay, oats, bran, and the like; this would

would prevent the occasion: and if they were already a little infected, some salt given with their dry food, would be a happy means of curing them.

ROTA, WHEEL, in mechanics. See the article **WHEEL**.

ROTATION, in geometry, a term chiefly applied to the circumvolution of any surface round a fixed and immoveable line, which is called the axis of its rotation: and by such rotations it is, that solids are conceived to be generated.

ROTATOIRES, in anatomy, the name by which some call the oblique muscles of the eye.

ROTATOIRES is also applied to the trochanters of the thigh bone.

ROTONDO, or **ROTUNDO**, in architecture, an appellation given to any building that is round both within and without-side, whether it be a church, a salon, or the like. The most celebrated rotondo of the ancients, is the Pantheon at Rome.

ROTULA, in anatomy, the same with the patella. See **PATELLA**.

ROTUNDUS, in anatomy, a name given to several muscles, otherwise called teres.

ROUCOU, the same with annotto. See the article **ANNOTTO**.

ROUGH-TREE, in naval affairs, a mast or yard which is unfinished, and is laid by the ship's side to serve as a rail, till a convenient opportunity offers to prepare it for service.

ROUNDELAY, a kind of ancient poem, thus termed, according to Menage, from its form, because it turns back again to the first verse, and thus goes round.

ROUND-HOUSE, in naval architecture, a sort of cabin raised on the after-part of a ship's quarter-deck in the merchant-service. It is usually the apartment of the captain, but occasionally of other officers, or passengers.

ROUNDING, in sea-affairs, certain pieces of old rope firmly wound about that part of the cable which is liable to be chafed or fretted against the stem, bows, or cut-water. The rounding is drawn very tight about the cable, and beat on with a mallet.

ROUNDING up a Tackle, the act of drawing the block or pulleys together when no weight is suspended by it.

ROUND, **ROUNDELAY**, in music, a kind of burden or ritornello, where the beginning of each couplet is repeated at the end thereof.

ROUT, a public road, highway, or course, especially that which military forces take. This word is also used for the defeat and flight of an army.

ROWER, in naval affairs, a person who manages the oars in a small ship, boat, or galley; and hence

ROWING is the art of managing the oars so as to move a vessel through the water. In this situation the oars act upon the vessel like a lever, whose fulcrum is the upper-part of the vessel's side; and

ROW-LOCK is the notch or opening in the side of the boat or galley, where the oar rests. In boats it is commonly limited by two pins, which are called thowles.

ROW-PORTS, little holes in the sides of a ship of war, wherein to thrust the oars when it is necessary to row.

ROWEL, among farriers, a kind of issue, made by drawing a skain of silk, thread, hair, or the like, through the nape of the neck, or other part, of a horse; answering to what, in surgery, is called a seton. See **SETON**.

The rowelling of horses is a method of cure frequently had recourse to, in cases of inward strains, especially about the shoulders or hips, as also for hard swellings not easy to be dissolved. The operation is this: a little slit being made through the skin, about an handbreadth below the part aggrieved, big enough to put a swan's quill in; the skin is raised from the flesh, the end of the quill put in, and the skin blown from the flesh upwards, and all over the shoulder; then the hole being stopped with the finger, the part blown is beat with an hazel-stick, and the wind spread with the hand all over, and then let go; this done, a skain of horse-hair, or red sarsenet, half the thickness of the little finger, is put in a rowelling needle seven or eight inches long, and the needle is put into the hole, and drawn through again, six or seven inches higher; then the needle is drawn out, and the two ends

of the rowel tied together, anointing it every day, as well as before the putting it in, with sweet butter and hog's grease, and drawing it backwards and forwards in the skin, to make the putrid matter discharge itself more plentifully.

Others, disliking these rowels, as making too large a sore and scar, use the French rowel, which is a round piece of stiff leather, with a hole in the midst, laying it flat between the flesh and skin, the hole in the rowel just against that in the skin, sewing it with a needle and thread drawn through the hole and the skin, cleaning it once in two or three days, and then anointing it afresh.

ROYALTIES, the rights of the king, otherwise called the king's prerogative, and the regalia.

RUBIA, madder, in botany, &c. See the article **MADDER**.

RUBIGO, a disease incident to corn, commonly called mildew, being a species of blight. See the article **BLIGHT**.

RUBRIC, *Rubrica*, in the canon law, signifies a title or article in certain ancient law-books; thus called because written, as the titles of the chapters in our ancient Bibles are, in red letters.

RUBRICS also denote the rules and directions given at the beginning, and in the course of, the Liturgy, for the order and manner in which the several parts of the office are to be performed. There are general rubrics and special rubrics, a rubric for the communion, &c. In the Romish Missal and Breviary are rubrics for matins, for lauds, for translations, beatifications, commemorations, &c.

RUBUS, the bramble, in botany, a genus of plants. See **RASPBERRY**.

RUBY, *rubinus*, in natural history, a species of the chrostitima class of gems, being a beautiful gem of a red colour with an admixture of purple. See the article **GEM**.

This, in its most perfect and best coloured state, is a gem of prodigious beauty and extreme value; it is often found perfectly pure and free from blemishes or foulness, but much more frequently debased greatly in its value by them, especially in the larger specimens. It is of very great hardness, equal to that of the sapphire, and second only to the diamond. It is various in size, but less subject to variations in its shape than most of the other gems. It is usually found very small, its most common size being equal to that of the head of the largest sort of pins; but it is found of four, eight, or ten carats; and sometimes, though very rare, up to twenty, thirty, or forty. It is never found of an angular or crystalliform shape, but always of a pebble-like figure, often roundish, sometimes oblong and much larger at one end than at the other, and in some sort resembling a pear, and is usually flatted on one side. It commonly is naturally so bright and pure on the surface, as to need no polishing; and when its figure will admit of being set without cutting, it is often worn in its rough state, and with no other than its native polish. Our jewellers are very nice, tho' not perfectly determinate, in their distinctions of this gem, knowing it, in its different degrees of colour, under three different names: the first is simply the ruby, the name given it in its deepest-coloured and most perfect state: the second is the spinel ruby; under this name they comprehend those rubies which are of a somewhat less bright colour than the ruby simply so called: the third is the balais-ruby; under this name they express a pale yet a very bright ruby, with a less admixture of the purple tinge than in the deeper-coloured one; this is of less value than the deeper one.

We have the true ruby only from the East Indies; and the principal mines of it are in the kingdom of Pegu and the island of Ceylon. We have in Europe crystals tinged to the colour of the ruby, but they have nothing of its lustre or hardness. The ruby seems to owe its colour to gold, it being possible to separate a small portion of gold from the little native rubies, and also to give the true colour of the ruby to fictitious paste by means of that metal.

The way of preparing a metalline colour from gold and tin, for tinging glass of a ruby colour, is, according to Shaw, as follows: Dissolve gold in aqua-regia, and dilute

dilute the fine yellow solution with a large proportion of fair water; to the mixture add a sufficient quantity of a saturated solution of tin, made also in aqua-regia, at several times, and a most beautiful red or purple-coloured powder will soon fall to the bottom of the containing glass; decant the liquor and dry the powder, a few grains whereof being melted along with white crystalline glass, will tinge it throughout of an extremely fine purple or ruby colour.

RUBY, in heraldry, denotes the red colour wherewith the arms of noblemen are blazoned; being the same which in the arms of others, not noble, is called gules.

RUCTATION, BELCHING, a ventosity arising from indigestion, and discharging itself at the mouth with a very disagreeable noise. There are belches owing to repletion, and others to inanition, or emptiness. Quincy says hypochondriac and hysteric persons are particularly liable to this disorder: They are rather to be cured with proper stomachics than carminatives and hot liquors.

RUDDER, in naval architecture, a piece of timber, or several pieces fastened together and fitted to the ship's stern-posts, to which it is hung by irons, whereon it moves, and thereby the ship is steered. *Murray's Ship-building.*

RUDBECKIA, DWARF SUN-FLOWER, in botany, a genus of plants, the compound flower of which is radiated; but the hermaphrodite corollulæ of the disc are tubulose and very numerous: the stamina are five very short capillary filaments; and there is a small orbiculated seed after each of the hermaphrodite corollulæ, and are all contained in the cup, affixed to a paleaceous receptacle.

RUDENTURE, in architecture, the figure of a rope or staff, sometimes plain, sometimes carved, with which the third part of the flutings of columns are frequently filled up.

RUDERATION, in building, a term used by Vitruvius for the laying of pavement with pebbles.

To perform the ruderation it is necessary that the ground be well beaten, to make it firm, and to prevent it from cracking; then a stratum of little stones are laid, to be afterwards bound together with mortar made of lime and sand. If the sand be new, its proportion may be to the lime as three to one; if dug out of old pavement or walls, as five to two.

RUDIMENTS, *Rudimenta*, the first principles or grounds of any art or science, called also the elements thereof. See the article ELEMENT.

RUFER HOOD, among falconers, a plain leathern hood, large and open behind, to be worn by an hawk when she is first drawn.

RULE, *Regula*, in matters of literature, a maxim, canon, or precept, to be observed in any art or science.

RULE, in arithmetic, denotes an operation performed with figures, in order to discover sums or numbers unknown.

The fundamental rules are addition, subtraction, multiplication, and division. See ADDITION, &c.

But, besides these, there are other rules denominated from their use; as the rule of alligation, fellowship, interest, practice, reduction, &c.

RULE of Three, or Rule of Proportion, commonly called the Golden Rule, a rule which teaches how to find a fourth proportional to three given numbers.

This rule is either direct, or reciprocal, called inverse. And those are both simple and compound.

RULE of Three Direct, or direct Proportion, is when, of four numbers, the first beareth the same ratio or proportion to the second as the third doth to the fourth.

As in these, $2 : 8 :: 6 : 24$.

Consequently, the greater the second term is, in respect to the first, the greater will the fourth term be, in respect to the third.

That is, as 8, the second term, is four times greater than 2, the first term; so is 24, the fourth term, four times greater than 6, the third term.

Whence it follows, that, if four numbers are in direct proportion, the product of the two extremes will always be equal to the product of the two means, as well in disjunct, as continued proportion.

For as $2 : 2 \times 4 :: 6 : 6 \times 4$. Or as $3 : 3 \times 5 :: 6 : 6 \times 5$,
or $3 \times 6 \times 5 = 3 \times 5 \times 6$.

But $2 \times 6 \times 4 = 2 \times 4 \times 6$.

That is, the product of the extremes is equal to that of the means.

Again, the less the second term is, in respect to the first, the less will the fourth term be, in respect to the third.

As in these, $2 : 8 :: 6 : 24$. Here $8 \times 6 = 48 = 24 \times 2$.

But, if $24 \times 2 = 48$, then will $48 \div 2 = 24$, or $48 \div 24 = 2$.

Note, any four numbers in direct proportion may be varied several ways. As in these,

Viz. if $2 : 8 :: 6 : 24$, then $2 : 6 :: 8 : 24$,
and $6 : 24 :: 2 : 8$, or $24 : 6 :: 8 : 2$, &c.

These variations, being well understood, will be of no small use in the true stating of any question in the Rule of Three.

All questions in direct proportion may be answered by three several theorems.

Theorem 1. Multiply the second and third terms together, and divide your product by the first term; the quotient will be the answer required.

yds.	shill.	yds.	shill.
Thus 3 :	9 ::	6 :	18 the answer.
	6		

3) 54 (18 shillings. } Because the second term was shillings.

Theorem 2. Divide the second term by the first, and multiply the quotient into the third term, and the product will be the answer required.

yds.	shill.	yds.	shill.
3 :	9 ::	6 :	18

Thus 3) 9 (= 3, then $3 \times 6 = 18$, as before.

Theorem 3. Divide the third term by the first, then multiply that quotient into the second term, and the product will be the answer.

yds.	shill.	yds.	shill.
3 :	9 ::	6 :	18

Thus 3) 6 (= 2, and $9 \times 2 = 18$, as before.

Here we see, that all the three theorems are equally true; but the first is most general, and usually practised: yet the two last may be readily performed, when either the second or third term can be divided by the first, and will be found of singular use in the rules of fellowship, &c.

Question 2. If 8 lb. of tobacco cost 14s. what will 56 lb. cost at the same rate?

Thus 8 lb. : 14s. :: 56 lb. : 4 l. 18 s. the answer,

14
—
224
56
—

8) 784 (= 98 s. = 4 l. 18 s.

Or thus 8) 56 (= 7, then $14 \times 7 = 98$ s. as before.

Question 3. If 14 shillings will buy 8 lb of tobacco, how much will 4 l. 18 s. buy after the same rate?

[Stated thus, $14 s : 8 lb :: 4 l. 18 s. —$

Then $56 \times 14 = 784$, and $14) 784 (56 lb. the answer.$

Question 4. If 56 lb of tobacco be worth 4 l. 18 s. how much may I buy for 14 s. at the same rate?

Stated thus, $4 l. 18 s. = 98 s. : 56 lb :: 14 s. : —$

Then $56 \times 14 = 784$, and $98) 784 (8 lb. the answer.$

Question 5. Suppose 4 l. 18 s. will buy 56 lb. of tobacco, what will 8 lb. of the same tobacco cost?

This question is thus stated, $56 lb. : 4 l. 18 s. = 98 s. :: 8 lb. —$

Then $98 \times 8 = 784$, and $56) 784 (= 14 s. the answer.$

Note, the three last questions are only the second varied, being proposed purely to give an instance how any question in this Rule of Three may be varied.

RULE of Three Inverse, or reciprocal Proportion, is, when, of four numbers, the third, (viz. that which moves the question) beareth the same ratio to the first, as the second does to the fourth.

Therefore, the less the third term is, in respect to the first, the greater will the fourth term be in respect to the second.

Example 1. If 16 men can do a piece of work in 6 days, how many days must 8 men require to do the same work, at the same rate of working?

Here it is plain, that 8 men must needs have more time than 16 men, to do the same work. Consequently, the greater the third term is, in respect to the first; the less will the fourth term be, in respect to the second.

Example 2. If 8 men can do a piece of work in 8 days, how many days will 16 men require to do the same work? Here it is plain, the fourth term must be less than the second, because 16 men undoubtedly can do the same work in less time than 8 men can.

For when, according to the true meaning or design of any question in proportion, more requires more, or less requires less, the terms are in direct proportion.

But if more require less, or less requires more, as above, then the terms will be in reciprocal proportion.

The manner of placing down the proposed terms is the same in both rules, viz. The first term in the supposition must be of the same kind and denomination with the third term, which moves the question; and the term sought must be of the same kind and denomination with the second term in the supposition; as in the two last examples.

	Men.	Days.	Men.	Days.
Thus in { Example 1.	16 :	6 ::	8 :	
Example 2.	8 :	12 ::	16 :	

The question being truly stated, observe this theorem.

Theorem. Multiply the first and second terms together, and divide their product by the third term; the quotient will be the answer required.

Thus in the second example, $12 \times 8 = 96$.

Then $16 \mid 96 (= 6 \text{ days, the answer required.})$

That is, 16 men may do the same work in 6 days, as 8 men can do in 12 days.

The reason of this operation, and, consequently, of the theorem, is grounded upon this consideration, viz. if 8 men require 12 days to do the work, it is plain one man would require 8 times 12 days, $= 96$ days, to do the same work; but if one man can do it in 96 days, most certain 16 men can do it in one 16th part of that time. Therefore 96, divided by 16, will give the answer required, viz. 16 $\mid 96$ (6, as before, &c.

DOUBLE RULE of Three, or Compound Proportion.

All questions in this rule, where five numbers are proposed to find a sixth, may more easily and readily be answered by one general theorem, which compriseth both the direct and inverse rules.

But, first, you must carefully note, that, in all questions of this nature, three of the five proposed terms are always conditional and supposed; and that the other two move the question, as for instance.

Example 1. If 100 l. will gain 6 l. in 12 months, what will 300 l. gain in 9 months? Solution. First say, if 100 l. gain 6 l. what will 300 l. gain? The answer will be 18 l. but this is gained in 12 months, therefore, in order to find how much is gained in 9 months, after the same rate, say, if 12 months give 18 l. what will 9 months give? The answer will be 13 l. 10 s.

Example 2. If 12 oxen eat up $3\frac{1}{2}$ acres of pasture in four weeks, and 21 oxen eat up ten acres of like pasture in 9 weeks, how many oxen will eat up 24 acres in 18 weeks?

Solution. If 12 oxen eat up $3\frac{1}{2}$ acres in 4 weeks, then by proportion 36 oxen in 4 weeks, or 16 oxen in 9 weeks, or 8 oxen in 18 weeks, will eat up 10 acres, on supposition that the grass did not grow. But since by reason of the growth of the grass, 21 oxen in 9 weeks can only eat up 10 acres, that growth of the grass in 10 acres for the last 5 weeks will be as much as would be sufficient to feed the excess of 21 oxen above 16, that is, 5 oxen for 9 weeks; or, which is the same thing, to feed $\frac{5}{2}$ oxen for 18 weeks; and in 14 weeks (the excess of 18 above the first 4) the increase of the grass, by analogy, will be such as to be sufficient to feed 7 oxen for 18 weeks; for it is, 5 weeks : 14 weeks :: $\frac{5}{2}$ oxen : 7 oxen. Wherefore add these 7 oxen, which the growth of the grass alone would suffice to feed, to the 8, which the grass without growth after 4 weeks would feed, and the sum will be 15 oxen; and lastly, if 10 acres suffice to feed 15 oxen for 18 weeks, then 24 acres will be found sufficient to feed 36 oxen for the same time.

RULE, in a monastic sense, a system of laws or regulations, whereby religious houses are governed, and which the religious make a vow, at their entrance, to observe. Such are the rules of the Augustines, Benedictines, Carthusians, Franciscans, &c.

RULES of Court, in law, are certain orders made, from time to time, in the courts of law, which attorneys are bound to observe, in order to avoid confusion; and both the plaintiff and defendant are at their peril also bound to pay obedience to rules made in court relating to the cause depending between them.

RULE, or RULER, an instrument of wood or metal with several lines delineated on it, of great use in practical mensuration.

When a ruler has the lines of chords, tangents, sines, &c. it is called a plane scale. See SCALE.

The carpenter's joint rule is an instrument usually of box, &c. twenty-four inches long, and one and a half broad; each inch being subdivided into eight parts. On the same side with these divisions, is usually added Gunter's line of numbers. On the other side, are the lines of timber and broad-measure; the first beginning at 82, and continued to 36, near the other end; the latter is numbered from 7 to 36, 4 inches from the other end.

Use of the Carpenter's Joint RULE. The application of the inches, in measuring lengths, breadths, &c. is obvious. That of the Gunter's line, see under GUNTER'S Line.

The use of the other side is all we need here meddle with: 1. The breadth of any surface, as board, glass, &c. being given, to find how much in length makes a square foot. Find the number of inches the surface is broad, in the line of broad-measure, and right against it is the number of inches required. Thus, if the surface were eight inches broad, eighteen inches will be found to make a superficial foot. Or more readily thus: apply the rule to the breadth of the board, or glass, that end, marked 36, being equal with the edge, the other edge of the surface will shew the inches, and quarters of inches, which go to a square foot. 2. Use of the table at the end of the board measure. If a surface be one inch broad, how many inches long will make a superficial foot? Look in the upper row of figures for one inch, and under it in the second row is twelve inches, the answer to the question. 3. Use of the line of timber-measure. This resembles the former; for having learned how much the piece is square, look for that number on the line of the timber-measure; the space thence to the end of the rule is the length which, at that breadth, makes a foot of timber. Thus, if the piece be nine inches square, the length necessary to make a solid foot of timber, is $21\frac{1}{2}$ inches. If the timber be small, and under nine inches square, seek the square in the upper rank of the table, and immediately under it is the feet and inches that make a solid foot. If the piece be not exactly square, but broader at one end than the other, the method is to add the two together, and take half the sum for the side of the square. For round timber the method is to girt it round with a string, and to allow the fourth part for the side of the square; but this method is erroneous, for hereby you lose nearly one fifth of the true solidity: though this is the method at present practised in buying and selling timber.

The mason's rule is twelve or fifteen feet long, in order to be applied under the level to regulate the courses, and make the piedroits equal, &c.

Everard's Sliding RULE has already been described under the article GAUGING.

Coggeshal's Sliding RULE is chiefly used for measuring the superficies and solidity of timber, &c. It consists of two rulers, each a foot long, one of which slides in a groove made along the middle of the other, as represented in plate CX. fig. 5.

On the sliding side of the rule are four lines of numbers, three whereof are double; that is, are lines to two radiuses; and one, a single broken line of numbers: the three first, marked A, B, C, are figured 1, 2, 3, &c. to 9; then, 1, 2, 3, &c. to 10; their construction, use, &c. being the same as those of Everard's sliding rule. The single line, called the girt line, and marked D,

R

whose

whose radius is equal to the two radiuses of any of the other lines, is broke for the easier measurement of timber, and figured 4, 5, 6, 7, 8, 9, 10, 20, 30, &c. From 4 to 5 it is divided into ten parts, and each tenth subdivided into 2, and so on, from 5 to 6, &c.

On the backside of the rule are, 1. A line of inch-measure, from 1 to 12; each inch being divided and subdivided. 2. A line of foot measure, consisting of one foot, divided into 100 equal parts, and figured 10, 20, 30, &c. The back part of the sliding piece is divided into inches, halves, &c. and figured from 12 to 24; so that, when drawn wholly out, there may be a measure of two feet.

Use of Coggeshal's RULE for Measuring plane Superficies. 1. To measure a square, suppose, for instance, each of the sides 5 feet; set 1 on the line B, to 5 on the line A; then against 5 on the line B is 25 feet, the content of the square on the line A. 2. To measure a long square. Suppose the longest side 18 feet, and the shortest 10; set 1 on the line B, to 10 on the line A; then against 18 feet, on the line B, is 180 feet, the contents on the line A. 3. To measure a rhombus. Suppose the side 12 feet, and the length of a perpendicular let fall from one of the obtuse angles to the opposite side, 9 feet; set 1 on the line B, to 12, the length of the side, on the line A; then against 9, the length of the perpendicular on the line B, is 108 feet, the content. 4. To measure a triangle. Suppose the base 7 feet, and the length of the perpendicular let fall from the opposite angle to the base 4 feet; set 1 on the line B, to 7 on the line A; then against half the perpendicular, which is 2 on the line B, is 14 on the line A, for the content of the triangle. 5. To find the content of a circle, its diameter being given. Suppose the diameter 3.5 feet; set 11 on the girt line D, to 95 on the line C; then against 3.5 feet on D is 9.6 on C, which is the content of the circle in feet. 6. To find the content of an oval or ellipsis. Suppose the longest diameter 9 feet, and the shortest 4. Find a mean proportional between the two, by setting the greater 9 on the girt line, to 9 on the line C; then against the less number 4 on the line C is 6, the mean proportional sought. This done, find the content of a circle, whose diameter is 6 feet; this, when found, by the last article, will be equal to the content of the ellipsis sought.

Use of Coggeshal's RULE, in Measuring Timber. 1°. To measure timber the usual way. Take the length in feet, half feet, and, if required, quarters; then measure half way back again; then girt the tree with a small cord or line; double this line twice very evenly, and measure this fourth part of the girt or perimeter, in inches, halves, and quarters. The dimensions thus taken, the timber is to be measured as if square, and the fourth of the girt taken for the side of the square, thus; set 12 on the girt line D, to the length in feet on the line C; then against the side of the square, on the girt-line D, taken in inches, you have, on the line C, the content of the tree in feet. For an instance: suppose the girt of a tree in the middle, be 60 inches, and the length 30 feet, to find the content, set 12 on the girt-line D, and 30 feet on the line C; then against 15, one fourth of 60, on the girt-line D, is 46.8 feet, the content on the line C. If the length should be 9 inches, and the quarter of the girt 35 inches; here, as the length is beneath a foot, measure it on the line of foot-measure, and see what decimal part of a foot it makes, which you will find .75. Set 12, therefore, on the girt-line, to 75 on the first radius of the line C; and against 35 on the girt-line is 64 feet on C, for the content. 2°. To measure round timber the true way. The former method, though that generally in use, is not quite just. To measure timber accurately, instead of the point 12 on the girt-line, use another, viz. 10.635; at which there should be placed a center-pin. This 10.635 is the side of a square equal to a circle, whose diameter is 12 inches. For an instance: suppose the length 15 feet, and $\frac{1}{4}$ of the girt 42 inches, set the point 10.635 to 15, the length; then against 42 on the girt-line is 233 feet for the content sought; whereas, by the common way, there arises only 184 feet. In effect, the common measure is only to the true measure, as 11 to 14. 3°. To measure a cube. Suppose the sides to be 6 feet each; set 12 on the girt-line

D, to 6 on C; then against 72 inches, the inches 6 feet on the girt-line, is 216 feet on C, which is the content required. 4°. To measure unequally-squared timber; that is, where the breadth and depth are not equal. Measure the length of the piece, and the depth at the end in inches: then find a mean proportional between the breadth and depth of the piece. This mean proportional is the side of a square, equal to the end of the piece; which found, the piece may be measured as square timber. For an instance: let the length of the piece of timber be 13 feet, the breadth 23 inches, and the depth 13 inches; set 23 on the girt-line D, to 23 on C; then against 13 on C is 17.35 on the girt-line D, for the mean proportional. Again, setting 12 on the girt-line D, to 13 feet, the length of the line C; against 17.35 on the girt-line is 27 feet, the content. 5°. To measure taper timber. The length being measured in feet, note one-third of it; which is found thus: set 3 on the line A, to the length on the line B; then against 1 on A is the third part on B: then, if the solid be round, measure the diameter at each end in inches, and subtract the less diameter from the greater; add half the difference to the less diameter; the sum is the diameter in the middle of the piece. Then set 13.54 on the girt to the length of the line C, and against the diameter in the middle on the girt-line is a fourth number on the line C. Again, set 13.54 on the girt-line to the third part of the length on the line C; then against half the difference on the girt-line is another fourth number on the line C; these two fourth numbers, added together, give the content. For an instance: let the length be 27 feet, one third whereof is 9, the greater diameter 22 inches, and the lesser 18; the sum of the two will be 40, their difference 4, and half the difference 2, which, added to the less diameter, gives 20 inches for the diameter in the middle of the piece. Now set 13.54 on the girt-line, to 27 on the line C, and against 20 on D is 58.9 feet. Again, set 13.54 of the girt-line to 9 on the line C; and against 2 on the girt-line, represented by 20, is .196 parts; therefore, by adding 58.9 feet to .196 feet, the sum is 59.096 feet, the content.

If the timber be square, and have the same dimensions; that is, the length 27 feet, the side of the greater end 22 inches, and that of the lesser 18 inches; to find the content; set 12 on the girt-line to 27, the length, on the line C, and against 20 inches, the side of the mean square on the girt-line, is 75.4 feet. Again, set 12 on the girt-line to 9 feet, one third of the length, on the line C, and against 2 inches, half the difference of the sides of the squares of the ends on the girt-line, is .25 parts of a foot; both together make 75.65 feet, the content of the solid.

The girt or circumference of a tree, or round piece of timber given; to find the side of the square within, or the number of inches of a side, when the round timber is squared. Set 10 on A to 9 on B, then against the girt on A are the inches for the side of a square on the line B.

RUM, a species of brandy, or vinous spirit distilled from sugar canes.

Rum, according to Dr. Shaw, differs from simple sugar-spirit, in that it contains more of the natural flavour, or essential oil of the sugar-cane; a great deal of raw juice and parts of the cane itself being often fermented in the liquor, or solution, of which the rum is prepared. The unctuous or oily flavour of rum is often supposed to proceed from the large quantity of fat used in boiling the sugar; which fat, indeed, if coarse, will usually give a stinking flavour to the spirit, in our distillations of the sugar-liquor, or wash, from our refining sugar-houses; but this is nothing of kin to the flavour of the rum, which is really the effect of the natural flavour of the cane.

The method of making rum is this: when a sufficient stock of the materials is got together, they add water to them, and ferment them in the common method, though the fermentation is always carried on very slowly at first; because, at the beginning of the season for making rum in the islands, they want yeast, or some other ferment to make it work; but by degrees, after this, they procure a sufficient quantity of the ferment, which rises up as a head

R U M

head to the liquor in the operation, and thus they are able afterwards to ferment and make their rum with a great deal of expedition, and in large quantities.

When the wash is fully fermented, or to a due degree of acidity, the distillation is carried on in the common way, and the spirit is made up proof; though sometimes it is reduced to a much greater strength, nearly approaching to that of alcohol or spirit of wine, and it is thus called double distilled rum. It might be easy to rectify the spirit, and bring it to much greater purity than we usually find it to be of; for it brings over in the distillation a very large quantity of the oil; and this is often so disagreeable, that the rum must be suffered to lie by a long time to mellow before it can be used; whereas, if well rectified, it would grow mellow much sooner, and would have a much less potent flavour.

The best state to keep rum in, both for exportation and other uses, is doubtless that of alcohol, or rectified spirit. In this manner it would be transported in one-half the bulk it usually is, and might be let down to the common-proof-strength with water when necessary: for the common use of making punch, it would likewise serve much better in the state of alcohol; as the taste would be cleaner; and the strength might always be regulated to a much greater exactness than in the ordinary way.

The only use to which it would not so well serve in this state, would be the common practice of adulteration among our distillers; for when they want to mix a large portion of cheaper spirit with the rum, their business is to have it of the proof strength, and as full of the flavouring oil as they can, that it may drown the flavour of the spirits they mix with it, and extend its own. If the business of rectifying rum was more nicely managed, it seems a very practicable scheme to throw out so much of the oil, as to have it in the fine light state of a clear spirit, but lightly impregnated with it; in this case it would very nearly resemble arrac, as is proved by the mixing a very small quantity of it with a tasteless spirit, in which case the whole bears a very near resemblance to arrac in flavour.

Rum is usually very much adulterated in England; some are so bare-faced as to do it with malt-spirit: the tastes of both are so nearly allied, that it is not easily discovered. The best method of judging of it is, by setting fire to a little of it; and when it has burnt away all the inflammable part, examining the phlegm both by the taste and smell.

A very ingenious gentleman has favoured us with his opinion in regard to the method of imitating the rum brought from the West Indian islands, or rather of making the same elsewhere.

The reason of this consideration, says he, is founded on a well known fact, viz. that from melasses, or the same ingredients as are made use of in the islands where the best rum is made, when they are distilled here, a spirit so different is obtained, that it is not even pretended to be rum at all, but bears the denomination of melasses spirits; and, in the northern colonies of America, also, only a very inferior kind of rum is produced from the same ingredients. Now it is certainly a speculation of some utility, as well as curiosity, to determine to what this difference is owing: and to know, if it can be done, how to produce rum here, instead of the common melasses spirits, from the melasses; and, in North America, to make such as is equal to that distilled in the islands.

The cause why melasses affords rum in the islands, and a spirit of a different kind here, or of the same kind, but not equally good, in North America, has been ascribed to three principles.

The first is, that the fermentation renders the spirit different, in this manner, from the effect of the difference of climate. The second is, that the melasses being used there while new, are then in a better state for this purpose. The third is, that the distilling the rum in large vessels, and suffering part of the melasses and feculences to adhere to the still, as is practised in the islands, occasions a part of the melasses to be burnt, and consequently to produce a considerable quantity of empyreumatic oil of a peculiar kind, which, rising with the vinous spi-

R U M

rit, mixes with it, and gives it the particular flavour, and oily nature of rum.

As to the first reason, or the difference of fermentation in the West Indies, and here, it might account for some variation in the produce: but, certainly, not such as is really found in the case of rum and melasses spirit. The great dissimilitude betwixt them lies, in the first wholly wanting that acido-dulcid taste, and oily consistence, that is found in the other; and which is obviously owing to part of the melasses being burnt; and affording an empyreumatic oil, that cannot be the product of any mode of fermentation, but must be the effect only of a considerable degree of heat, either during, or before the distillation.

The same may be alleged, as to the second assigned reason of this difference, or the newness and freshness of the melasses. For all that would result from thence would be, that the new would be less acid than the older, which could only make a small variation in the spirit produced, and that of a very different nature from what is really perceived betwixt our melasses spirits and rum; for, it is well known, by those who practise imitations of brandy and rum, that acids dulcify the spirit, and render it less fiery, and more gentle; and, in the counterfeit rum, a considerable quantity of oil of vitriol is therefore used, to destroy the taste of empyreuma, or fainits, as it is called, of the malt spirit, and gives it a softness; so that, instead of rendering the spirit more unlike rum, the keeping the melasses, till they tend towards an acid state, would rather promote the resemblance. The peculiar oily consistence, and flavour of rum, can certainly never be the consequence of using the melasses in a fresher or staler state. For, if it had been so, the fact would soon have shewn itself, by the difference of the melasses spirits distilled here; which must, of course, in some cases, have approached nearly to, or actually have been good rum: as it may be supposed, the melasses must sometimes have been used as newly here, as in the West India islands; and this would necessarily have led to their being always used so, if such an advantageous consequence had been once known to have attended it.

The last reason, therefore, or the burning of the melasses in the still, if any of the three be, must prove the true one. It was first hinted, in part, by Mr. Smith, in a pamphlet, as a supplement to his work on the Art of Distillery. He there asserts, as a fact, that it was the general custom for the negroes to omit the perfectly cleansing the stills, which are very large: and, that a great quantity of the feculence and melasses adhered, consequently, to the bottom of them, and was continually burnt; and, to the empyreumatic oil of the sugar, contained in the melasses, and thus burnt, he attributed the peculiar flavour and oiliness of the rum. Admitting this fact, there can be no doubt but that the difference of rum, from other spirits distilled from fermented sugar and melasses, must consist in this circumstance; and, indeed, it is evident, from the very flavour and oily nature of the rum itself, that the addition of an empyreumatic oil of this kind, really constitutes this difference.

If this be allowed, as there is the greatest reason it should, a method naturally presents itself, of bringing any spirit, distilled, either in Europe or North America, from sugar or melasses, to a very close resemblance, or rather, perhaps, sameness of nature, with the rum produced in the West-India islands.

This method is the burning a proper quantity of sugar or melasses in the due degree; and adding to it the fermented liquor of melasses before the distillation: by which means it is, on this supposition, presumed, that what is wanting, to render the spirit distilled from such liquor the same with rum, must be of course supplied.

The degree of burning, and the proportion of the burnt matter to be added to the fermented liquor, for this purpose, must depend on experiment; but a few trials would ascertain it; and if the difference of rum consists in this, as there is great room to think it does, as well from just observation on the nature of the subject, as from Mr. Smith's authority for the fact; the practice of this method might be rendered of commercial utility. The particular advantages of this would here be, by converting what is now
melasses

melasses spirits into rum, and greatly increasing its marketable value: and, in North America, by enabling distillers of rum there to bring theirs to a much greater resemblance to that of the islands; and consequently to make a much more advantageous return of the melasses, they purchase by the barter of their own produce: a circumstance, at present, of great consequence, both to the peace and lucrative interest of those colonies.

The rendering rum, by this means, cheaper, would, also, tend to the exclusion of those wretched counterfeit kinds, made of malt spirits, dulcified with a large proportion of acid, particularly oil of vitriol; which are very injurious to particular constitutions. Extreme great quantities of such counterfeit kinds are now vended: and so much industry has been exercised in the art of making them, that the preparing mixtures, for producing the resemblances of the various genuine spirits, is now become a separate trade: and the possessors of it are called flavour makers. All such practices ought either to be under due regulations, or be wholly prohibited: for, being in the hands of persons ignorant of the salutary or injurious effects of the mixtures they make, ingredients very detrimental may be introduced; and dispensed, by this means, amongst a great number of the common people, who never consult any thing but their palate, in matters of this nature.

RUMEN, in comparative anatomy, the paunch, or first stomach of such animals as chew the cud, thence called ruminant animals.

RUN, the after-part of a ship's bottom both within or without, which grows narrower as it approaches the stern-post.

RUNDLE, or **ROUNDLE**, in heraldry, the same with **PELLET**.

RUNDLET, or **RUNLET**, a small vessel containing an uncertain quantity of any liquor, from three to twenty gallons.

RUNET, or **RENNET**, the acid juice found in the stomachs of calves that have fed on nothing but milk, and are killed before the digestion is perfect.

RUNNING of Goods, a clandestine landing of goods, without paying the legal customs or duties for the same.

RUPEE, **ROUPIA**, or **ROUPIAS**, names of gold and silver coin, current in the East Indies.

RUPTURE, in surgery, the same with hernia. See **HERNIA**.

RURAL, or **RUSTIC**, in general, denotes something that relates to the country.

RUSSIA, or **MUSCOVY**, a large empire, comprehending a vast extent of country, in the most northerly parts of Europe and Asia, from twenty to one hundred and thirty degrees of east longitude, and between forty-five and seventy-two degrees of north latitude.

RUST of a Metal, the flower or calx thereof, procured by corroding and dissolving its superficial parts by some menstruum. Water is the great instrument or agent in producing rust; and hence oils, and other fatty bodies, secure metals from rust; water being no menstruum to oil, &c. and therefore not able to make its way through it.

All metals are liable to rust, even gold itself, if exposed to the fumes of sea-salt.

RUST of Corn, in husbandry, the name given by our farmers to a disease in corn or other vegetables, in which their stalks and leaves seem burnt up, and appear of a sort of rust colour.

Wheat is blighted at two seasons, first in the blossom, and then its generation is prevented, many of the husks being empty in the ear, and the rudiments of the grains not impregnated: secondly, wheat is blighted when the grains are brought to maturity; and in this case they become light, and are of little value for making of bread, having scarce any flour in them.

The first of these cannot happen in England from frosts, because our wheat is not in flower till the month of June; but it is long and continual rains that chill the blossoms, and in this manner prevent their fertility: this, however, does not often happen to us; these rains are not common at this season of the year; and, if they were, this country lying much of it open, the winds dislodge these drops of water from the ears, and prevent the mischief they would do there.

Lammas wheat does not retain these drops so long as the bearded or cone wheat; and, in consequence of this in the terrible blight in England, in the year 1725, the bearded wheat received infinitely greater mischief than the Lammas wheat.

The second kind of blight from light ears, is that which is more frequent, and more general with us; this brings the greatest scarcity of wheat, and the cause of this is plainly want of nourishment of the grain, by whatever means that want is occasioned. Several accidents kill the plants, or injure their health, and in that case the grains are not filled; lightning does great mischief to the farmer in this kind, as is plain by the several black spots and patches in fields of corn, in years when there has been more lightning than usual. This is a disaster that must be quietly suffered, since it can neither be prevented nor remedied; but the other causes of blights, which are most general, and do the most damage, may be prevented in some measure at least.

One great and common cause of the blight is the lodging or falling of corn; in this case the stalks are broken near the ear, and the vessels are hurt which should carry up the nourishment to the ear. In this case, there can just juices enough pass for the keeping the plant alive, and bringing it to its full height, but it is languid all the time, and the grains can never be filled with flour. The earlier in the season this lodging of the stalks happens, the thinner and poorer the ears will be: hence it happens, that when dung and tillage have brought a wheat land into so good a state, that in April and May it seems to promise the farmer five or six quarters of wheat, it shall all be destroyed by falling in June, and scarce yield him five bushels, and this is so thin and lank, that the expences of reaping and threshing are more than its value. The wind is generally accused of the throwing down these stalks; but this does not seem to be truly the case; the wind may press upon the plants; but the cause of their giving way to it is a weakness in their stalks, and this seems either owing to the want of nourishment, or the want of air, or of the sun's rays, and perhaps the want of all three together. A rich acre will maintain a crop of five quarters standing, while a poor acre will not be able to support such a crop, as would have yielded only about three quarters, had it stood. This is a proof of want of due nourishment being one great cause of the falling. Air is necessary to the nourishment of all plants; wheat in particular requires a very free air. It succeeds best in open hilly places where the wind comes freely to it, and shakes off the drops of water from the leaves, as well as their own recrements; and it is plain, that a great quantity of the sun's rays is necessary to keep the wheat strong; because in the hotter countries it is not so subject to fall, as it is with us, and in other northern countries.

There is another cause of the blight, which is the wheat's coming too late into blossom. It should blossom in the beginning of June, because there is not otherwise time, during the hot weather, for it to pass through the different stages to the perfection of the grain.

The causes of the blight being thus known, the cure or prevention may be attempted by the farmer on much more rational grounds than it was among the antients. It is advantageous to hasten as much as possible the time of blossoming of the corn, and to protract, as long as we can, the ripening of the grain, that it may have sufficient time to fill and swell.

The earliest sown wheat is generally observed to escape the best, and this is owing to its coming soonest into blossom.

The antients used to let their sheep feed upon the corn while young in the blade, by way of preventing it from lodging or falling afterwards: some of our own farmers use this method also; and it is true, that the corn is prevented from falling by this; but the remedy is as bad as the disease, for the stalks are not made very strong by this practice, but the ears lighter. They therefore do not weigh down and lodge the stalks indeed, but they are in some sort blighted by this means, and the disease is caused by the means used to prevent it. This feeding down the wheat with sheep retards the time of its blossoming, and the only advantage of early sowing is thus taken

taken away by it: what grows after the eating of the sheep is a sort of latter crop, and is always weaker and later than the first.

The longer the corn remains on the ground, the more nourishment it requires from it; and, in this unnatural remaining on the land, there is no proper supply provided.

The general remedy for all the cases of the blight is the modern method of horse-hoeing husbandry. In this the hoe stirs up the ground as often as the farmer pleases, and every such stirring gives new life and nourishment to the plant: this, as a supply of food for the ear, may be given, whenever it is necessary, and the wide intervals left for the hoe in the drilling the wheat; for this sort of husbandry gives a free passage for the sun and air to all the plants.

The most general blight of all that happen in these cold countries is caused by insects, which some think are brought in the air by an east-wind, accompanied by moisture, a little before the grain is filling with that milky juice which hardens into flour. These insects deposit their eggs within the outer skin or rind of the stalks; and when the young ones are hatched, they feed on the parenchyma, and eat off many of the vessels which should convey this juice; then the ear is deprived of it, and must in consequence be thin and poor, in proportion to the number of the vessels eaten, and as the insects happen to come earlier or later; for sometimes they come so late, that the grains are sufficiently filled with this milky juice before they have any power to hurt the vessels.

In this case, though the straw, when examined by the microscope, appears to have its vessels eaten and torn, and to be full of black specks, which are caused by the same insects, yet the grain is plump and full. This is one of the many cases in which the early sown wheat escapes the blight. It has been seen, that, of the crop of wheat in the same field, some of which has been sown earlier and some later, tho' there has been no difference in the whole, yet the early sown wheat has been full-eared, and the late sown has been light-eared; and both have had their stalks equally eaten and spotted by the insects.

A proof that these mischievous insects are brought by the east-wind, is, that the corn on the east side of hedges is often found blighted, and destroyed by them, while that on the west side of the same hedge is unhurt. Some suppose they are bred in the earth, and crawl up the stalks, because some whole fields are subject to them, and others escape them wholly; but this is more probably owing to the difference of the situation of these fields, as they are more or less exposed to the east.

Some wheat is more liable to be hurt by this insect blight than another, and the best remedy in this evil is to plant fields, which are most exposed to these blights, with such wheat as is least subject to be injured by them. The white cone, or bearded wheat, which has its stalk or straw like a rush, not hollow, but full of pith; except near the lower part, where it is very thick and strong, is very proper on this occasion; it is probable that this plant has sap vessels, that lie deeper, and so are not to be destroyed like those of common wheat: the stalks of this are often found spotted with black, which shews that the insects have been there, and yet the ears are found full, and the grains plump in them.

There is another kind of blight, called by the farmers moor loor; this is occasioned by the earth's falling away from the roots of the wheat, and is cured by throwing up small furrows against the rows in the drilling method. The horse-hoeing husbandry is best of all others calculated to prevent blights, and to cure them when they happen; but, as there are some years when all wheat is blighted, even at these times, the horse-hoeing husbandry has an advantage; for, when the stalks fall, they never lie absolutely on the ground in this case, but the air has room to play between them; but the common sown wheat has not this advantage. The ears in the blighted wheat of the drilled kind are not so light nor poor as in others, but make the farmer some amends in the corn, though greatly less than in the common produce. *Tull's Horse-hoeing Husbandry.*

Corn is always more subject to blights after a wet summer than at any other season; the reason seems, that, the roots being continually drenched with water, the plant runs up to stalk, and has very little ear, and the corn is never large or full.

It is observed, that when the mildews rise, or blights fall, they generally infect only one kind of grain, sometimes wheat, sometimes oats, and sometimes barley only; and the same sort of observation holds good in regard to fruit; sometimes only apples are blighted, sometimes only pears, sometimes cherries, and so on. *Mortimer's Husbandry.*

RUSTIC, in architecture, implies a manner of building in imitation of nature, rather than according to the rules of art.

RUSTIC WORK, is where the stones in the face, &c. of a building, instead of being smooth, are hatched, or picked with the point of a hammer.

RUSTIC ORDER, that decorated with rustic quoins, rustic work, &c.

RUSTRE, in heraldry, a bearing of a diamond shape, pierced through in the middle with a round hole.

RUT, in hunting, the venery, or copulation of deer.

RUE, *Ruta*, in the materia medica, a small shrubby plant, with thick bluish leaves divided into numerous roundish segments: on the tops of the branches come forth yellowish tetrapetalous, sometimes pentapetalous, flowers followed each by a capsule, which is divided into four partitions full of small blackish rough seeds. It is cultivated in gardens, flowers in June, and holds its leaves all the winter. The markets are frequently supplied with a narrow-leaved sort, which is cultivated in preference to the other, on account of its appearing variegated during the winter with white streaks.

This herb has a strong unpleasant smell, and a penetrating pungent bitterish taste: much handled, it is apt to inflame and exulcerate the skin. It is recommended as a powerful stimulant, aperient, antiseptic, and as possessing some degree of an antispasmodic power; in crudities and indigestion, for preserving against contagious diseases and the ill effects of corrupted air, in uterine obstructions and hysteric complaints, and externally in discutient and antiseptic fomentations. Among the common people, the leaves are sometimes taken with treacle on an empty stomach, as an anthelmintic. A conserve, made by beating the fresh leaves with thrice their weight of fine sugar, is the most commodious form for the exhibition of the herb in substance.

The virtues of rue are extracted both by water and rectified spirit, most perfectly by the latter: the watry infusions are of a greenish yellow or brownish; the spirituous, made from the fresh leaves, of a deep green; from the dry, of a dark yellowish brown colour. The leaves themselves, in drying, change their bluish green colour to a yellow. On inspissating the spirituous tincture, very little of its flavour rises with the menstruum; nearly all the active parts of the rue remaining concentrated in the extract, which impresses on the palate a very warm, subtle, durable pungency, and is in smell rather less unpleasant than the herb in substance. In distillation with water, an essential oil separates; in colour yellowish or brownish, in taste moderately acid, and of a very penetrating smell, rather more unpleasant than that of the herb: a very considerable part of the virtue of the rue remains behind; the decoction, inspissated, yielding a moderately warm, pungent, bitterish extract. The active matter of this plant appears therefore to be chiefly of the more fixed kind: the essential oil itself is not very volatile, or at best, is so strongly locked up by the other principles, as not to be readily elevated in distillation. The seeds, and their capsules, appear to contain more oil than the leaves.

Goat RUE, galego, a plant with a papilionaceous flower, and a long cylindric pod for its fruit.

It has been accounted a good sudorific, but is little used in the present practice.

RYE, *Secale*, in botany, a genus of plants, the corolla of which consists of two valves; the exterior valve is rigid, ventricose, acuminate and compressed, its lower edge is ciliated, and it terminates in a long arista: the interior valve is lanceolated and plane; the corolla serves

the office of a pericarpium, inclosing the seed, and, at a proper time, opening and dropping it out; the seed is single, oblong, and almost cylindric.

This sort of grain succeeds very well on any sort of dry land, even on the most barren gravel or sand. The farmers sow it about the beginning of September, after a summer's fallow, in the driest time they can. Two bushels of seed is the quantity generally allowed to an acre of land; but if it be ground newly broken up, or if it be subject to worms, they then allow a peck more to the acre. A little sprinkling of dung, or mud, upon rye-land, will greatly advance the crop, though it is laid but half the thickness that it is for other corn; its produce is commonly about twenty bushels upon an acre.

The farmer knows it is ripe when the straw is yellow, the ear bends, and the grain feels hard. It is not apt to shed the seeds; and therefore, if there are many weeds among the crop, it may be left lying upon the ground, or gravel, as they call it, eight or nine days after it is cut, before it is bound up, if the weeds are not dry sooner: for otherwise, they will grow moist in the barn, and cause the whole to give, and not to thrash well, and sometimes they will make it musty.

As it is a grain that will grow in the ear sooner than any other if it be wet, care must be taken, if rain falls after it is cut, to turn it as it lies upon the ground every other day, and at the same time to keep the ears as far from the earth, and as much above the stubble, as may be; this will prevent the mischief. If it be pretty clear of weeds, it may be housed as soon as it is cut. If either this grain or wheat lodge upon the ground, it is best to cut them, even though they are not ripe; for the stalk being broken will yield no more nourishment to the ear.

There is another very essential use to the farmer made of rye. April is the season of the year when food is of all others the scarcest for cattle, especially for sheep and lambs: on this occasion some split the ridges of the wheat stubble, and sow them with rye; they harrow this in, allowing about a bushel to an acre; they feed the sheep with this in April, and in May they plow it up for fallow. *Mortimer's Husbandry.*

In many parts of France there have been certain years, in which this grain, from no apparent cause, has proved noxious, and sometimes even poisonous. Mr. Perrault, travelling through Sologne, was informed that the rye of that province was sometimes so corrupted, that those who eat of the bread that had much of the corrupted grain in it, were seized with gangrenes in different parts of the body, which was not preceded by any fever, inflammation, or any considerable pain; and that the gangrened parts usually fell off after a time of themselves, without the assistance of surgical instruments.

The grains of rye thus degenerated are black on the outside, and tolerably white within; and, when they are dry, they are harder and closer than the natural good grain: they have no ill taste, but sometimes they have a viscous metallic like honey hanging to one end of them. They grow longer than the other grains in the same ear,

and are found, from one or two, to seven or eight in the same ear. Some have supposed that these were not the proper seeds of the plant, but some other extraneous bodies that got in among them; but it is evident, from a close inspection, that they are really the genuine seeds only altered by some accident; the coats, and the furrow, and even the germen for the young plant, being entirely the same as in the natural seeds.

The places where the rye is found to degenerate in this manner, are all a dry and sandy soil. In these places there is scarce any soil in which more or less of these large seeds are not found among the others, but, when there are but few of them, the ill effects are not perceived. The season when the degeneracy is greatest, and the effects the worst of all, is, when there have been excessive rains in the spring, and there come on excessive heats in the succeeding summer.

The bread which is made of the rye that holds ever so much of this bad corn, is not distinguishable from other rye bread by the taste, and seldom produces its ill effect, till some considerable time after it is taken. Besides the gangrenes already mentioned, it not unfrequently brings on other bad consequences, such as drying up the milk of women who give suck, and occasioning sometimes malignant fevers, accompanied with drowsiness, ravings, and other dangerous symptoms.

The part usually seized by the gangrene is the legs, and this often in a very frightful manner. The arms are the parts most subject next, but all the other parts of the body are subject to it.

The first symptom of this approaching gangrene is a stupefaction and deadness in the part; after this there comes on some pain, though not violent, and the skin becomes livid; sometimes the skin shews no mark of it, but the pain and swelling increase; and it is necessary to make an incision into the flesh to find the gangrened part. In the more desperate cases, the only remedy is the taking off the part; and, if this is neglected, the flesh is all wasted, and the skin becomes black, and clings round the bones, and the gangrene appears again in the shoulders.

The poorer people are only subject to this disease; and, as they principally eat the rye bread, and as those years when there is most of this bad grain among the ears of rye produce most of these disorders, it has been judged certain that the rye is the occasion of it. It may deserve enquiry, however, whether that grain may not be innocent of the mischief, and its degeneracy and the distemper attributed to it may not both be the effect of the same bad constitution of the air. If it proves, on enquiry, that only those who eat of the rye are subject to the disease, it will seem a proof of its really being owing to it; and in this case the mischief may be prevented by the sifting the grain before it is ground, the degenerated grains being so long that they will all remain in the sieve that lets the other through. The experiment has been made on the spot, by giving the flour of the corrupted grains alone to animals; but it is said, they have been killed by it. *Phil. Transf. N^o. 130.*

S.

S A B

S, a consonant, and the eighteenth letter of the alphabet. This letter was used in the same form by the ancient Greeks, as appears from the Sigeian inscription, only in an inverted position. Its sound is formed by driving the breath through a narrow passage between the palate and the tongue elevated near it, together with a motion of the lower jaw towards the upper, the lips being a little way open, with such a special configuration of every part of the mouth and larynx as renders the voice something sibilous or hissing. The old and new orthography of the French differ chiefly in the use of the *s*; the latter omitting it in writing where it is not heard in pronunciation, and the former retaining it. Thus the followers of the one, particularly the Academy in their dictionary, *tempeste*, *huître*, *fuste*, those of the other, *tempête*, *hûtre*, *fûte*.

s, among the ancients, was a numerical letter, signifying seven.

s. A. in medical prescriptions, is an abbreviation of *secundum artem*, according to the rules of art; chiefly used where some uncommon care and dexterity is required.

SABÆANS, in church history, a set of idolators, much ancients than the Jewish law.

In the early ages of the world, idolatry was divided between two sects; the worshippers of images called Sabæans, or Sabians, and the worshippers of fire called magi. See **MAGI**.

The Sabæans began with worshipping the heavenly bodies, which they fancied were animated by inferior deities. In the consecration of their images, they used many incantations to draw down into them from the stars those intelligences, for whom they erected them, whose power and influence they held afterwards dwelt in them. This religion, it is said, first began among the Chaldæans, with their knowledge in astronomy: and from this it was, that Abraham separated himself, when he came out of Chaldæa. From the Chaldæans it spread all over the East; and from thence to the Grecians, who propagated it to all the nations of the known world. The remainder of this sect still subsists in the East, and pretend to derive their name from Sabius, a son of Seth; and among the books in which the doctrines of this sect are contained, they have one which they call the Book of Seth, and which they pretend was written by that patriarch.

SABBATH, or the day of rest, a solemn festival of the Jews, on the seventh day of the week, or Saturday, beginning from sun-set on Friday, to sun-set on Saturday.

The observation of the sabbath began with the world: for God having employed six days in its creation, appoint-

S A B

ed the seventh, as a day of rest to be observed by man, in commemoration of that great event. On this day the Jews were commanded to abstain from all labour, and to give rest to their cattle. They were not allowed to go out of the city farther than two thousand cubits, or about a mile; a custom which was founded on the distance of the ark from the tents of the Israelites, in the wilderness, after their leaving Egypt; for being permitted to go, even on the sabbath-day, to the tabernacle to pray, they from thence inferred, that the taking a journey of no greater length, though on a different account, could not be a breach of the sabbatical rest.

As the seventh day was a day of rest to the people, so was the seventh year to the land; it being unlawful in this year to plow or sow, and whatever the earth produced, belonged to the poor; this was called the sabbatical year. The Jews, therefore, were obliged, during the six years, and more especially the last, to lay up a sufficient store for the sabbatical year.

The modern, as well as the ancient, Jews are very superstitious in the observance of the sabbath; they carry neither arms, nor gold, nor silver about them; and are permitted neither to touch these, nor a candle, nor any thing belonging to the fire; on which account they light up lamps on Friday, which burn till the end of the sabbath.

There is at present a sect of Baptists called Sabbatarians, from their observing the seventh day of the week, as a day set apart for the worship of God: they attempt to justify this practice by alleging that the Jewish sabbath was never abrogated in the New Testament; and that where God has given a command, it is our duty to observe it till he has abrogated or altered it by a new command. See **SUNDAY**.

SABELLIANS, a sect of Christians of the third century, that embraced the opinions of Sabellius, a philosopher of Egypt, who openly taught that there is but one person in the godhead.

The Sabellians maintained, that the word and the holy spirit are only virtues, and held, that he who is in heaven is the father of all things, descended into the virgin, became a child, and was born of her as a son; and that having accomplished the mystery of our salvation, he diffused himself on the apostles in tongues of fire, and was then denominated the Holy Ghost. This they explained by resembling God to the sun, the illuminative virtue or quality of which was the word, and its warming virtue the Holy Spirit. The word, they taught, was darted, like a divine ray, to accomplish the work of redemption; and that, being reascended to heaven, the influences of the Father were communicated after a like manner to the apostles.

SABINA,

SABINA, savin, in botany. See SAVIN.

SABLE, or SABLE ANIMAL, in zoology, a creature of the weasel kind, called by authors mustela zibellina.

SABLE, in heraldry, denotes the colour black, in coats of arms belonging to gentlemen; but in those of noblemen it is called a diamond; and in those of sovereign princes, saphire.

It is expressed in engraving by perpendicular and horizontal hatches crossing one another.

SABRE, a kind of sword or scymetar, with a very broad and heavy blade, thick at the back, and a little falcated or crooked towards the point; it is the ordinary weapon worn by the Turks, who are said to be very expert in the use of it.

SAC, in law, is said to be an ancient privilege, which the lord of a manor claims of holding his court, in causes of trespass among his tenants, and imposing fines for the same.

SACCADE, in the manege, is a jerk more or less violent, given by the horseman to the horse, in pulling or twitching the reins of the bridle all on a sudden, and with one pull, and that when a horse lies heavy upon the hand, or obstinately arms himself.

SACCHARUM SATURNI, SUGAR OF LEAD, is thus ordered to be made in the London Dispensatory: boil cerufs with distilled vinegar, until the vinegar becomes sufficiently sweet; then filter the vinegar through paper, and after due evaporation set it to crystallize.

Some have ventured to give sugar of lead internally, in doses of a few grains, as a styptic, in hæmorrhages, profuse colliquative sweats, seminal fluxes, the fluor albus, &c. and indeed it must be allowed, that it very powerfully restrains the discharge; but then it occasions other symptoms, often dangerous, and sometimes fatal; as violent colic pains, obstinate constipations, cramps, tremors, &c. so that its internal use seems by no means innocent.

SACCULUS, in anatomy, a diminutive of faccus, signifies a little bag.

SACERDOTAL, something belonging to priests.

SACK of Wool, a quantity of wool containing just twenty-two stone, and every stone fourteen pounds. In Scotland, a sack is twenty-four stone, each stone containing sixteen pounds.

SACK of Cotton-Wool, a quantity from one hundred and a half to four hundred weight.

SACKS of Earth, in fortification, are canvas-bags filled with earth. They are used in making retrenchments in haste, to place on parapets, or the head of the breaches, &c. or to repair them, when beaten down.

SACKBUT, a musical instrument of the wind-kind, being a sort of trumpet, though different from the common trumpet both in form and size: it is fit to play a bass, and is contrived to be drawn out or shortened, according to the tone required, whether grave or acute.

It takes asunder in four pieces, and has frequently a wreath in the middle, which is the same tube only twice twisted, or making two circles in the middle of the instrument, by which means it is brought down one fourth lower than its natural tone: it has also two pieces or branches on the inside, which do not appear, unless drawn out by an iron-bar, and which lengthens it till it hit the tone required.

The sackbut is usually eight feet long, without reckoning the circles, and without being drawn out: when it is extended to its full length, it is usually fifteen feet; the wreath is two feet nine inches in circumference.

SACRAMENT, *Sacramentum*, signifies, in general, a sign of a thing sacred and holy; and is defined to be an outward and visible sign of a spiritual grace. Thus there are two objects in a sacrament, the one the object of the senses, and the other the object of faith: Protestants admit only of two sacraments, baptism, and the eucharist, or Lord's supper: but the Roman Catholics own seven, viz. baptism, confirmation, the eucharist, penance, extreme unction, ordination and marriage.

SACRAMENTARIANS, a name given by the Romanists to all such as in their opinion entertain erroneous doctrines of the sacrament of the Lord's supper,

and chiefly used by way of reproach to Lutherans, Calvinists, and other protestants.

SACRED, something holy, or that is solemnly offered and consecrated to God, with benedictions, unctions, &c.

SACRIFICE, a solemn act of religious worship, which consisted in dedicating or offering up something animate or inanimate on an altar, by the hands of the priest, either as an expression of their gratitude to the Deity for some signal mercy, or to acknowledge their dependence on him, or to conciliate his favour.

The origin of sacrifices is by some ascribed to the Phœnicians, but Porphyry ascribes it to the Egyptians, who first offered the first-fruits of their grounds to the gods, burning them upon an altar of turf: thus in the most ancient sacrifices there were neither living creatures, nor any thing costly or magnificent; and no myrrh or frankincense. At length they began to burn perfumes; and afterwards men leaving their ancient diet of herbs and roots, and beginning to use living creatures for food, they began also to change their sacrifices. The scriptures, however, furnish us with a different account; for Noah, as it is said, sacrificed animals at his coming out of the ark; and even Abel himself sacrificed the best and fattest of his flock; but Grotius thinks it more probable that he contented himself with making a mere oblation of his lambs, &c. without slaying them.

The Jews had two sorts of sacrifices, taking the word in its largest signification: the first were offerings of tythes, first-fruits, cakes, wine, oil, honey, and the like; and the last offerings of slaughtered animals. When an Israelite offered a loaf or a cake, the priest broke it in two parts, and setting aside that half which he reserved for himself, broke the other into crumbs, poured oil, wine, incense, and salt upon it, and spread the whole upon the fire of the altar. If these offerings were accompanied with the sacrifice of an animal, they were thrown upon the victim to be consumed along with it. If the offerings were of the ears of new corn, they were parched at the fire, rubbed in the hand, and then offered to the priest in a vessel, over which he poured oil, incense, wine and salt, and then burnt it upon the altar, having first taken as much of it, as of right belonged to himself.

The principal sacrifices among the Hebrews consisted of bullocks, sheep and goats; but doves and turtles were accepted from those who were not able to bring the other; these beasts were to be perfect and without blemish. The rites of sacrificing were various, all of which are very minutely described in the books of Moses.

The manner of sacrificing among the Greeks and Romans was as follows: In the choice of the victim, they took care that it was without blemish or imperfection; its tail was not to be too small at the end; the tongue not black, nor the ears cleft; and that the bull was one that had never been yoked. The victim being pitched upon, they gilt his forehead and horns, especially if a bull, heifer, or cow. The head they also adorned with a garland of flowers, a woollen infula or holy fillet, whence hung two rows of chaplets with twisted ribbands; and on the middle of the body a kind of stole, pretty large, hung down on each side; the lesser victims were only adorned with garlands and bundles of flowers, together with white tufts or wreaths.

The victims thus prepared were brought before the altar; the lesser being driven to the place, and the greater led by an halter; when if they made any struggle or refused to go, the resistance was taken for an ill omen, and the sacrifice frequently was set aside. The victim thus brought was carefully examined, to see that there was no defect in it: then the priest, clad in his sacerdotal habit, and accompanied with the sacrificers and other attendants, and being washed and purified according to the ceremonies prescribed, turned to the right hand and went round the altar, sprinkling it with meal and holy water, and also besprinkling those who were present. Then the cryer proclaimed with a loud voice, Who is here? To which the people replied, Many and good. The priest then having exhorted the people to join with him by saying, Let us pray, confessed his own unworthiness, acknowledging that he had been guilty of divers sins;

sin; for which he begged pardon of the gods, hoping that they would be pleased to grant his requests, accept the oblations offered them, and send them all health and happiness; and to this general form added petitions for such particular favours as were then desired. Prayers being ended, the priest took a cup of wine, and having tasted it himself, caused his assistants to do the like; and then poured forth the remainder between the horns of the victim. Then the priest, or the cryer, or sometimes the most honourable person in the company, killed the beast, by knocking it down, or cutting its throat.

If the sacrifice was in honour of the celestial gods, the throat was turned up towards heaven: but if they sacrificed to the heroes or infernal gods, the victim was killed with its throat towards the ground. If by accident the beast escaped the stroke, leaped up after it, or expired with pain and difficulty, it was thought to be unacceptable to the gods.

The beast being killed, the priest inspected its entrails, and made predictions from them. They then poured wine, together with frankincense, into the fire, to increase the flame, and then laid the sacrifice on the altar; which in the primitive times was burnt whole to the gods, and thence called an holocaust: but, in after-times, only part of the victim was consumed in the fire, and the remainder reserved for the sacrificers; the thighs and sometimes the entrails being burnt to their honour, the company feasted upon the rest. While the sacrifice was burning, the priest, and the person who gave the sacrifice, jointly prayed, laying their hands upon the altar. Sometimes they played upon musical instruments in the time of the sacrifice, and on some occasions they danced round the altar, singing sacred hymns in honour of the gods.

SACRILEGE, the crime of profaning sacred things, or those devoted to the service of God.

SACRISTAN, *Sacrista*, a church officer, otherwise called sexton.

SACRISTY, *Sacristia*, in church-history, an apartment in a church, where the sacred utensils were kept: being the same with our vestry.

SACRO-LUMBARIS, in anatomy, one of the extensor muscles of the back and loins, has its origin at the os sacrum and the posterior spine of the ilium, and its termination in the upper part of the ribs.

SACRUM Os, the sacred bone, in anatomy, the lower extremity of the spina dorsa, being a bone of a triangular figure, with a rough surface; its substance is spongy, and it has two lateral apophyses for its articulation with the ossa innominata, also two smaller upper apophyses, with glenoid cavities for the articulation into the lower vertebra; and an inferior apophyses, for its articulation with the os coccygis: it has also a canal, for the end of the spinal marrow.

The uses of this bone are, 1. To serve as a basis to the spine. 2. To form the pelvis along with the ossa innominata, and to defend the parts contained in it. 3. To contain in its sinus the lower part of the spinal marrow, called cauda equina. 4. To give passage at its foramina, which are sometimes four, sometimes five pair, to the nerves of the intestinum rectum, the bladder, and of the parts of generation, and to the large crural and ischiatic ones. 5. To serve as a place of origin to many of the muscles.

In adults, the os sacrum is one continued bone; but, in infants, it is almost entirely cartilaginous; and in children more grown up, it always consists of several pieces, the junctures of four or five of which may be seen even in adults.

SADDLE is a seat upon a horse's back, contrived for the convenience of the rider.

SADDLES, amongst seamen, a sort of wooden crutches nailed on the upper-side of the main and fore-yard-arms, whereon to fix the studding-sail booms, which slide out upon them when the studding-sails are to be set.

SADDUCEES, in Jewish antiquity, a famous sect among the ancient Jews, so called from their founder Sadoc Antigonus of Socho, president of the sanhedrim at Jerusalem, and teacher of the law in the principal divinity-school of that city. Having often, in his lectures, asserted to his scholars, that they ought not to serve God

in a servile manner, with respect to reward, but only out of filial love and fear; two of his scholars, Sadoc and Baithus, inferred from thence, that there were no rewards or punishments after this life; and, therefore, separating from the school of their master, they taught that there was no resurrection, nor future state. Many embracing this opinion, gave rise to the sect of the Sadducees, who were a kind of Epicureans, but differing from them in this, that though they denied a future state, yet they allowed the world was created by the power of God, and governed by his providence; whereas the followers of Epicurus denied both.

The Sadducees denied all manner of predestination whatever, and not only rejected all unwritten traditions, but also all the books of the Old Testament, excepting the Pentateuch.

SAFE-CONDUCT, a security given by the king under the great seal to a foreigner, for his safe coming into and passing out of the kingdom.

SAFE-GUARD, a protection formerly granted to a stranger, who feared violence from some of the king's subjects, for seeking his right by course of law.

SAFFRON, *Crocus*, in botany, &c. See the article **CROCUS**.

SAGAPENUM, in pharmacy, &c. the concrete gummy-resinous juice of an oriental plant, of which we have no certain account, but which appears, from the seeds and pieces of stalks sometimes found among the juice as brought to us, to be of the ferulaceous or umbelliferous kind. The sagapenum comes immediately from Alexandria: either in distinct tears, or run together into large masses; outwardly of a yellow colour, internally somewhat paler, and clear like horn; growing soft on being handled, so as to stick to the fingers. It is sometimes supplied in the shops by the larger and darker coloured masses of bdellium broken in pieces; which greatly resemble it in appearance, but may be distinguished by their much weaker smell.

Sagapenum has a strong disagreeable smell, somewhat of the leek kind, or like that of a mixture of galbanum with a little asafetida; and a moderately hot biting taste. It is one of the strongest of the deobstruent gums, and frequently prescribed, either by itself, or in conjunction with ammoniacum or galbanum, in hysterical cases, uterine obstructions, asthmas, and other disorders. It may be commodiously taken in the form of pills, from two or three grains to a scruple or half a dram: In doses of a dram, it loosens the belly.

SAGATHEE, in commerce, a slight kind of woollen stuff, serge, or ratteen, sometimes mixed with a little silk.

SAGE, *Salvia*, in botany, a low shrubby plant, with square stalks, obtuse wrinkled dry leaves set in pairs, and large bluish labiated flowers, in loose spikes on the tops of the branches: the upper lip of the flower is nipt at the extremity, the lower divided into three segments. It is a native of the southern parts of Europe, common in our gardens, and flowers in June.

There are two species of sage, namely, the common sage, and the small sage, or sage of virtue.

Common sage with the leaves nearly oval, but acuminate, is sometimes green and sometimes red: both the green and red sorts rise from the seeds of one and the same plant.

Small sage, or sage of virtue, with narrow leaves, is generally whitish, never red, and most of them have at the bottom a piece standing out at each side in the form of ears.

The leaves and tops of sage are moderately aromatic and corroborant, and used in debilities and relaxations both of the nervous and vascular system. Their smell is pretty strong and not disagreeable; their taste somewhat warm, bitterish, and subastringent: with solution of chalybeate vitriol, they strike a deep black colour. The second sort is both in smell and taste the strongest, the first most agreeable. Of both kinds, the flowers are weaker and more grateful than the leaves; and the cup of the flower stronger, and obviously more resinous, than any other part.

The leaves of sage give out their virtue both to water and rectified spirit, most perfectly to the latter: to the

T

former

former they impart a brownish, to the latter a dark green tincture. The watery infusion is often used as tea, and often acidulated with a little lemon juice for a diluent in febrile distempers: the spirituous tincture is in taste stronger than the watery, but the smell of the sage is by this menstruum covered or suppressed.

SAGENE, a Russian long measure, five hundred of which make a werst: the sagene is equal to seven English feet.

SAGITTA, in astronomy, the arrow, or dart, a constellation of the northern hemisphere, near the eagle; consisting of five stars, according to Ptolemy and Tycho; but in Mr. Flamsteed's catalogue, of no less than twenty-three.

SAGITTA, in botany, implies the top of any small twig, cyon, or graft of a tree.

SAGITTA, in trigonometry, the same with the versed sine of an arch.

SAGITTAL *Suture*, in anatomy, the second of the genuine sutures of the cranium or skull.

SAGITTARIES, the ARCHER, in astronomy, the ninth sign of the zodiac. See ZODIAC.

The stars in this constellation in Ptolemy's catalogue are thirty-two, in Tycho's sixteen, and in Mr. Flamsteed's fifty-two.

SAGO, a simple brought from the East-Indies, of considerable use in diet as a restorative.

Sago is a sort of bread produced in the following manner, from a tree called landan, growing in the Moluccas. When a tree is felled, they cleave it in two in the middle, and dig out the pith, which is eatable, when it comes fresh out of the tree. They pound it in a mortar, till it is reduced into a kind of powder somewhat like meal. Then they put it in a sarse made of the bark of the same tree, placing it over a cistern made of its leaves, and pour water on it, which separates the pure part of the powder from the woody fibres wherewith the pith abounds. The flour thus filtrated they call sagu, which they make into paste, and bake it in earthen furnaces.

SAILING, in a general sense, implies the art or act of navigating; or of determining the various motions of a ship, and her true place at any time.

Plane, or Plain SAILING, is that performed by means of the plane chart. See PLANE CHART.

Before we proceed to shew the method of solving the several cases of plane sailing, it may be necessary to observe, that the distance sailed, difference of latitude, and the departure, or difference of longitude, constantly form a right-angled triangle, and the course steered, and the complement of the course, are the two oblique angles of the same triangle. For suppose a ship at L (plate CX. fig. 6.) sails on a direct course till she arrives at M; then will LM represent the distance sailed, LN the difference of latitude, NM the departure, or difference of longitude, and the angle NLM the course steered, constituting the right-angled triangle LMN, right-angled at N. Whence it follows, that, if any two of these are given, we can by trigonometry find the rest.

Case I. One latitude, course, and distance sailed being given, to find the other latitude; and departure from the meridian.

Example. Suppose a ship, in the latitude of 4 deg. 10 min. north, sails S. S. W. 194 miles; required the latitude she is in, and how far she hath departed from her former meridian?

Geometrically. Let the place of the ship be O (see plate CX. fig. 7.) draw the meridian OP, and the right-line OQ, forming an angle with the meridian OP = 22 deg. 30 min. = 2 points, the course steered; set off on the line OQ 194 miles, the distance sailed, from O to Q; from the point Q let fall the perpendicular QP, on the meridian OP, and the triangle is constructed; and the lines OP and PQ, the difference of latitude and departure, may be measured by applying them to graduated lines on the chart, or to the same scale of equal parts which OQ was taken from.

Arithmetically. 1. For the difference of latitude, or side OP, the proportion will be,

As radius ——— = 90 d. 00 m. = 10.0000000
To the distance OQ ——— = 194 = 2.2878017
So is the co-sine of the course = 67° 30' = } 9.9656153
angle Q = ———

To the difference of latitude OP = 179 = 2.2534170
2. For the departure, or side PQ,

As radius ——— = 90 d. 00 m. = 10.0000000
To the distance sailed OQ ——— = 194 = 2.2878017
So is the sine of the course 22 d. 30 m. = angle O = 9.6006997

To PQ, the departure required — = 77 = 1.8885014

Case II. Both latitudes and course being given, to find the distance and departure.

Example. Suppose a ship, in the latitude of 3 deg. 10 min. south sails N. E. by N. till her distance of latitude be 2° 20'; required the distance sailed, and departure from the meridian?

Geometrically. Let R (see plate CX. fig. 8.) be the place the ship sailed from on the chart; draw the meridian RS, setting off on it 140 miles = the difference of latitude, from R to S; and erect the perpendicular ST, draw the rhumb-line RT, making an angle with the meridian RS = 33 deg. 45 min. = the course steered, continuing it till it cut the perpendicular in T; then will T be the place of the ship on the chart; and the distance RT, and departure ST, may both be measured by applying them to the graduated lines, or the same scale RS was taken from.

1. To find the distance sailed, it will be,
As the comp. of the course = 56 d. 15 m. = } 9.9198464
angle T = ———
To the difference of latitude = 140 = RS = 2.1461280
So is radius ——— = 90 d. — = 10.0000000

To the distance required — = 168,4 = RT = 2.2262816

2. For the departure, the proportion will be,
As radius ——— = 90 ——— = 10.0000000
To the distance RT ——— = 168,4 ——— = 2.2262816
So is the sine of the course, or angle R = 33 d. 45 m. = ——— } 9.7447390

To ST, the departure required = 93,5 = 1.9710206

Case III. Both latitudes and distance sailed being given, to find the course and departure.

Example. Admit a ship, in the latitude of 1 d. 00 m. south, sails between the north and east 96 miles, till her difference of latitude be 1° 10', required the course and departure?

Geometrically. Let V (plate CX. fig. 9.) be the place of the ship sailed from on the chart; draw the meridian VW, setting off on it 70, the difference of latitude, from V to W, and erect a perpendicular WX; take the distance sailed between the points of the compasses, and, setting one foot in V, with the other cross the perpendicular in X, which will be the place the ship is arrived at on the chart; and the course or angle WVX may be measured by the line of chords, and the departure WX by applying it to the graduated lines on the chart, or to the same scale VX was taken from.

Arithmetically. 1. To find the course, or angle WVX, it will be,
As VX the distance sailed — = 96 — = 1.9822712
To radius ——— = 90 d. 00 m. = 10.0000000
So is VW, the diff. of latitude = 70 — = 1.8450980

To the S of the angle X, the comp. course = } 9.8628268
46 d. 49 m. = ———
Which being taken from 90 d. gives 43 d. 11 m. the course steered; and, because the course was between the north and east, it is north 43 d. 11 d. easterly, or nearly N. E. by N. 3 quarters easterly.

2. For the departure WX, the proportion will be,
As radius ——— = 90 d. 00 m. — = 10.0000000
To the distance VX ——— = 96 ——— = 1.9822712
So is the sine of the course, or angle V = } 9.8352688
43 d. 11 m. = ———

To the departure WX ——— = 65,7 ——— = 1.8175400

Case

Case IV. Both latitudes and departure being given, to find the course and distance?

Example. Suppose a ship, in the latitude 2d. 00m. south, sails between the south and east, till her difference of latitude be 2° 10', and her departure 96 miles east; required her direct course and distance?

Geometrically. Let a (plate CX fig. 10.) be the first place of the ship on the chart, draw the meridian ab , setting off on it 130 miles, the difference of latitude, from a to b , and erect the perpendicular bc , making it = 96 miles, the departure from the meridian; through the points a and c , draw a right-line, and the triangle is constructed; and the angle a may be measured by the line of chords, and the distance ac by applying it to the graduated lines on the chart.

Arithmetically. 1. To find the course, it will be,
As ab , the difference of latitude = 130 — = 2.1139434
To radius — — — = 90d. 00m. = 10.0000000
So is bc the departure — — — = 96 = 1.9822712

To the T. of the angle a , the course required } 9.8683278
= 36d. 27m. = — — — — — }
Which, because she sailed between the south and east, is south 36d. 27m. easterly, or almost S. E. by S. one quarter easterly.

2. To find the distance sailed, it will be,
As the sine of the course, or angle a = 36d. 27m. = — — — — — } 9.7738749
Is to the departure bc — — — = 96 — — — = 1.9822712
So is radius — — — = 90d. 00m. = 10.0000000

To ac , the distance sailed — — — = 161.5 = 2.2083963

Case V. One latitude, distance, and departure being given, to find the other latitude and course steered.

Example. A ship at sea, in the latitude of 1d. 00m. north, sails between the north and west 120 miles, having departed to the westward of her former meridian 96 miles; required her direct course, and the difference of latitude?

Geometrically. Let d (plate CX fig. 11.) be the place of the ship: draw the meridian de , and parallel to it, at the distance of the departure = 96, the line fg ; take the distance sailed between the points of the compasses, and, setting one foot in d , with the other cross the former parallel in h , which will be the place the ship is arrived at; from the point h , let fall the perpendicular he , and draw the right-line dh ; then will de be the difference of latitude, and the angle d the course; both which may be measured as in the former case.

Arithmetically. 1. To find the course, the proportion will be,
As dh , the distance sailed — — — = 120 — — — = 2.0791812
To radius — — — = 90d. 00m. — — — = 10.0000000
So is de , the departure — — — = 96 — — — = 1.9822712

To the sine of the course, or angle d = 53d. 7m. = 9.9030900, that is north 53d. 7m. westerly, or almost N. W. 3 quarters westerly.

2. For the difference of latitude, it will be,
As radius — — — = 90d. 00m. — — — = 10.0000000
To dh , the distance sailed — — — = 120 — — — = 2.0791812
So is the co-sine of the course — — — = 53d. 07m. = 9.7782870

To de , the difference of latitude = 72 — — — = 1.8574682

Case VI. One latitude, course, and departure being given, to find the other latitude and distance sailed.

Example. Suppose a ship, in the latitude of 3 deg. 10 min. south, sails N. W. by N. till her departure be 90 miles, required her direct distance, and the latitude she is in?

Geometrically. Let k (plate CX fig. 12.) be the first place of the ship; draw the meridian kl , and the rhumb-line km , forming an angle with the meridian = 33 deg. 45 min. the course steered; at the distance of 90 miles, the departure, draw the line no , parallel to kl , then will m be the place the ship is arrived at; from the point m , let fall the perpendicular ml ; then will km be the distance, and kl the difference of latitude, both which may be measured, by applying them to the graduated lines on the chart.

Arithmetically. 1. To find the distance sailed, it will be,

As the sine of the course, or angle k = 33d. 45m. = — — — — — } 9.7447390
To the departure lm — — — = 90 — — — = 1.9542425
So is radius — — — = 90d. 00m. = 10.0000000

To the distance km — — — = 162 — — — = 2.2095035

Mercator's SAILING, the method of performing the several cases of sailing according to Mercator's projection.

Under the article MERCATOR's Chart, we have shewn the nature of this projection, with the method of constructing a table of meridional parts, to which we refer the reader; and shall proceed to shew the method of solving the several cases of Mercator's sailing.

Case I. The latitudes and longitudes of two places being given, to find the course and distance between them.

Example. Required the direct course and distance between the Lizard in the latitude of 50 deg. 00 min. north, longitude 5 deg. 14. min. west, and a port in the latitude of 32 deg. 20. min. north, and longitude 17 deg. 30 min. west?

Geometrically. 1. Draw the meridian bkd (plate CX fig. 13.) and from b the Lizard, set off the meridional difference of latitude to d ; through d draw the parallel cd , setting off on it the difference of longitude from d to c , and draw the line bc ; then will c represent the given port.

2. Make bke equal to the proper difference of latitude, and draw kl parallel to dc . Then will the angle cbe be the direct course, bl the distance, and el the departure, which may be measured, the course by the line of chords, and the distance bl by the scale of equal parts.

As all the cases of Mercator's Sailing are projected after the same manner, we shall, for the sake of brevity, omit it in the following cases:

Arithmetically. As bd , the meridional difference of latitude — 1422.5 — — — } 3.1530523
Is to radius — — — = 90d. 00m. — — — = 10.0000000
So is dc , the difference of longitude — 736 — — — = 2.8671728

To the tangent of the angle cbe , the direct course = 27d. 22 min. — — — — — } 9.7141205
Which is south 27 deg. 22 min. westerly, or nearly south-south-west a quarter westerly, because the port lies to the westward of the Lizard.

Then, to find bl the distance, it will be,
As radius — — — = 90d. 00m. — — — = 10.0000000
To bke , the proper diff. of latitude 1060 — — — = 3.0253059
So is the sec. of the ang. lbe , the cour. 27° 22' 10.0515465

To bl , the direct distance — 1193.6 — — — = 3.0768524

Case II. One latitude, course, and distance sailed being given, to find the other latitude and difference of longitude.

Example. A ship in the latitude of 40 deg. 00 min. north, longitude 20 deg. west, sails south 51 deg. 10 min. westerly, 1020 miles; required the latitude she is in, and her difference of longitude?

1. As radius — — — = 90d. 00m. — — — = 10.0000000
To the distance sailed — — — = 1020 — — — = 3.0086002
So is the co-sine of the course — 51d. 10m. — — — = 9.7973071

To the proper difference of latitude 640 — — — = 2.8059073
Hence the ship will be in the latitude of 29 deg. 20 min. north; whence the meridional difference will be = 780.3. Then it will be,

As radius — — — = 90d. 00m. — — — = 10.0000000
To the meridional diff. of latitude — 780.3 — — — = 2.8922616
So is the tangent of the course — 51d. 10m. — — — = 10.0942155

To the difference of longitude — 970 — — — = 2.9864771

Case III. Both latitudes and course being given, to find the distance sailed, and difference of longitude.

Example. A ship, in the latitude of 40 deg. 00 min. north, sails south 51 deg. 10 min. westerly, till she be found by observation to be in the latitude of 29 deg. 20 min.

min. north; required the direct distance sailed and difference of longitude?

As radius ————— 90d. 00m. — 10,0000000
To the proper difference of latitude 640 — 2,8059073
So is the secant of the course — 51d. 20m. — 10,2026929

To the direct distance ————— 1020 — 3,0086002

Then, having found the meridional difference of latitude = 780,3, it will be,

As radius ————— 90d. 00m. — 10,0000000
To the meridional diff. of latitude — 780,3 — 2,8922616
So is the tangent of the course — 51d. 10m. — 10,0942155

To the difference of longitude — 970 — 2,9864771

Case IV. Both latitudes and distance sailed being given, to find the course steered and difference of longitude.

Example. A ship, in the latitude of 40 deg. 00 min. north, sails between the south and west 1020 miles, and is then found by observation to be in the latitude of 29 deg. 20 min. north; required the course steered, and difference of longitude?

As the distance sailed ————— 1020 — 3,0086002
Is to radius ————— 90d. 00m. — 10,0000000
So is the proper difference of latitude — 640 — 2,8059073

To the co-sine of the course — 51d. 10m. — 9,7973071
Whence the meridional difference of latitude will be = 780,3, and the difference of longitude found by the following proportion:

As radius ————— 90d. 00m. — 10,0000000
To the merid. difference of latitude — 780,3 — 2,8922616
So is the tangent of the course — 51d. 10m. — 10,0942155

To the difference of longitude — 970 — 2,9864771

Case V. One latitude, course, and difference of longitude being given, to find the other latitude and distance sailed.

Example. Suppose a ship, in the latitude of 40 deg. 00 min. north, sails south 51 deg. 10 min. westerly, until her difference of longitude be 970 miles; required the distance sailed, and what latitude she is in?

As the tangent of the course — 51d. 10m. — 10,0942155
To the difference of longitude — 970 — 2,9864771
So is radius ————— 90d. 00m. — 10,0000000

To the meridional difference of lat. 780,3 — 2,8922616

And, because the ship is sailing towards the equator, therefore,

From the merid. parts of the lat. sailed from } 2622,7
40d. 00m. ————— }
Take the meridional difference of latitude — 780,3

Remain the mer. parts of the lat. arrived in 29° 20' 1842,4
Whence the proper difference of latitude will be 640.

Then, to find the distance sailed, it will be,

As radius ————— 90d. 00m. — 10,0000000
To the proper diff. of latitude — 640 — 2,8059073
So is the secant of the course — 51d. 10m. — 10,2026989

To the distance sailed ————— 1020 — 3,0086002

And, because the ship is sailing towards the equator, and, consequently, decreasing the latitude; therefore,

d. m.
From the latitude sailed from ————— 40 : 00 north
Take the difference of latitude — 640 = 10 : 40

Remains the latitude she is in — 29 : 20 north

Case VI. One latitude, course, and departure being given, to find the other latitude, distance, and difference of longitude.

Example. Suppose a ship in the latitude 40d. 00m. north, longitude 20d. 00m. west, sails south 51d. 10m. westerly till she have departed from her former meridian 794,6 miles; required the distance sailed, difference of longitude, and what latitude she is in?

1. As the sine of the course — 51d. 10m. — 9,8915226
To the departure ————— 94,6 — 2,9001486
So is radius ————— 90d. 00m. — 10,0000000

To the distance ————— 1020 — 3,0086260

2. As the tangent course — 51d. 10m. — 10,0942155
To the departure ————— 794,6 — 2,9001486
So is radius ————— 90d. 00m. — 10,0000000

To the proper difference of lat. — 640 — 2,8059331

And, as the ship is constantly decreasing her latitude, therefore the difference of latitude, being taken from the latitude sailed from, will give 29 deg. 20 min. north, the latitude the ship is in; whence the meridional difference of latitude will be 780,3.

Then, to find the difference of longitude, it will be,

As radius ————— 90d. 00m. — 10,0000000
To the meridional diff. of lat. — 780,3 — 2,8922616
So is the tangent of the course — 51d. 10m. — 10,0942155

To the diff. of long. — 970 — 2,9864771

Case VII. The departure and both latitudes being given, to find the course, distance, and difference of longitude.

Example. Suppose a ship in the latitude of 40 deg. 00 min. north, 20 deg. 00 min. west longitude, sails between the south and west till she be found by observation to be in the latitude of 29 deg. 20 min. north, and to have departed from her former meridian 794,6 miles; the course steered, distance sailed, and difference of longitude are required?

1. As the proper difference of latitude 640 2,8059073
To radius ————— 90d. 00m. — 10,0000000
So is the departure — 794,6 — 2,9001486

To the tangent of the course 51d. 10m. — 10,0942155

2. As the sine of the course 51d. 10m. 9,8915226
To the departure ————— 794,6 — 2,9001486
So is radius ————— 90d. 00m. — 10,0000000

To the distance ————— 1020 — 3,0086260

Then, having found the meridional difference of latitude, the difference of longitude will be found by the following proportion:

As radius ————— 90d. 00m. — 10,0000000
To the merid. diff. of latitude — 780,3 — 2,8922616
So is the tangent of the course 51d. 10m. 10,0942155

To the difference of longitude — 970 — 2,9864771

Or it may be found by the log. tangents, thus,
As the tang. of the log. rumb. 51d. 30m. 19f. 10,1015093
To the log. of the remainder — 985,825 — 2,9937899
So is the tang. of the course 51d. 10m. — 10,0942155

To the difference of longitude — 970 — 2,9864961

Case VIII. One latitude, distance sailed, and departure being given, to find the other latitude, course, and difference of longitude.

Example. A ship in the latitude of 40 deg. 00 min. north, longitude 20 deg. 00 min. west, sails between the south and west 1020 miles, and is found to have departed from her former meridian 794,6 miles; required the course steered, difference of longitude, and what latitude she is in?

1. As the distance ————— 1020 — 3,0086002
To radius ————— 90d. 00m. — 10,0000000
So is the departure — 794,6 — 2,9001486

To the sine of the course — 51d. 10m. — 9,8915484

2. As radius ————— 90d. 00m. — 10,0000000
To the distance ————— 1020 — 3,0086002
So is the co-sine of the course — 51d. 10m. — 9,7973071

To the proper difference of lat. — 640 — 2,8059073

Hence it appears, that the ship's true course is south 51 deg. 10 min. westerly, or nearly south-west half westerly, and that she is in the latitude of 29 deg. 20 min. north; whence the meridional difference of latitude is 780,3; and to find the difference of longitude, it will be,

As radius ——— god. oom. — 10,0000000
 To the merid. differ. of latitude — 780,3 — 2,8922616
 So is the tang. of the course — 51d. 10m. — 10,0942155

To the difference of longitude — 970 — 2,9864771

Middle Latitude SAILING, a method of performing the problems of sailing by the help of the middle latitude, which nearly agrees with Mercator.

Current SAILING. See *CURRENT*.

Parallel SAILING, the method of finding the distance run, when a ship sails under a parallel, or on a direct east or west course.

Under the article *DEGREE*, we have shewn the method of finding the length of a degree of longitude in any latitude, and given a table for that purpose; by the help of which, all the propositions relating to parallel sailing may be easily solved.

SAILS, in navigation, are large cloths of canvas, formed by a combination of small ones, whose edges are sewed together by double seams, and whose skirts are surrounded by a rope called the bolt-rope. They are extended on or between the masts, to catch the wind, whereby the ship is impelled along the surface of the water. See *MAST*, *YARD*, and *BOLT-ROPE*.

There is a great variety of sails in every ship, as suited to the force or direction of the wind. The principal ones are the courses and top-sails, which are spread by the lower and the top-sail yards. See *COURSE* and *TOP-SAIL*.

The sails on the main-mast are the main-sail, which is the lowest and largest, next the top-sail, and above it the top-gallant-sail. On the fore-mast, in the same position, the fore-sail, the fore-top-sail, and fore-top-gallant-sail; and on the mizen-mast, the mizen, the mizen-top-sail, and mizen-top-gallant-sail. Above the main and fore-top-sails there is frequently a small light sail, hoisted in fair weather and light winds, called the royal; and without the skirts of the main-sail, fore-sail, main and fore-top-sails, there are also thin sails, extended in fair winds, called the studding-sails. See the article *STUDDING-Sail*.

The sails spread between the masts are most usually triangular; these are termed stay-sails, being hoisted upon the stays, which descend obliquely from the mast-heads.

The sails upon the bow-sprit are the jib, fore-stay-sail, sprit-sail, and sprit-sail-top-sail.

Besides these there are many others which are set occasionally, as the driver, ring-tail, water-sail, cross-jack, &c. &c.

The stay-sails, between the mizen and main-masts, are denominated the mizen-stay-sail, mizen-top-mast-stay-sail, and mizen-top-gallant-stay-sail.

Those between the main and fore-masts are termed the main-stay-sail, main-top-mast-stay-sail, middle-stay-sail, and main-top-gallant-stay-sail.

The stay-sails before the fore-mast are already described, as being on the bow-sprit, to be the jib and fore-stay-sail; there is also sometimes a fore-top-mast-stay-sail, or inner jib.

There are several different methods of sailing, as quartering, large, afore the wind, and close hauled. See *QUARTERING*, &c.

The motion of sailing communicated to the ship is thus elegantly described by the ingenious M. Bouguer.

When a ship sails out of a harbour, she acquires her motion by infinitely slow degrees, much after the same manner as heavy bodies, in their fall, arrive not at a certain velocity, but by an infinite repetition of the action of their weight.

The first impulsions of the wind greatly affect the velocity, because the resistance of the water might destroy them; for the velocity being at first small, the resistance of the water, which depends thereon, will be very weak; but the faster the ship goes, the less will be the force of the wind on the sails; whereas it is quite otherwise with respect to the impulsion of the water on the bow, because it augments in proportion to the velocity with which the ship sails. So the new degrees which the effort of the sails adds to the motion of the ship, are continually decreasing; whilst, on the contrary, those which

diminish the resistance of the bow are continually encreasing. The velocity is accelerated in proportion as the quantity added is greater than that subtracted; but, when these two powers become equal, when the impulsion of the wind on the sails has lost so much of its force as not to act, but in proportion to the force with which the resistance of the water acts on the bow, in the opposite sense, the ship will then go no faster, and will sail with a constant uniform motion. The great weight of the ship may be the cause of the ship's being so long in coming to her greatest velocity; but this weight makes nothing to the degree of velocity; and when the ship has once come to it, she afterwards goes on by her own intrinsic motion, and she can neither gain nor lose any new degree of velocity. She moves as by her own proper force in vacuo, without being afterwards subject either to the effort of the wind on the sails, or the resistance of water on the bow. If at any time the impulsion of the water on the bow should destroy any part of the velocity, the impulsion of the wind on the sails will repair it, so the motion will continue the same; but it must be observed, this will only be when these two powers act in a direction quite contrary to one another: otherwise they will not mutually destroy one another. The whole theory of working ships depends upon this opposition and perfect equality which should subsist between the impulsion of the water and the impulsion of the wind. *Traité du Navire*.

With regard to the sailing order of a fleet, see the article *SQUADRON*.

SAINT, in the Romish church, a holy person deceased, and since his decease canonized by the pope, after several informations and ceremonies.

SAINTFOIN, *Onobrychis*, in botany, &c. an artificial pasture much used for the feeding of cattle.

The roots of saintfoin are long, woody, black without and white within. They are perennial, and terminate at the surface of the ground in a head, whence rise the leaves and several stalks, two feet or two and a half long, of a reddish colour, and bending on all sides. The leaves of saintfoin are conjugated, and consist of several small leaves or folioles, green above, and white and velvety beneath: they terminate in a point, and are fastened by pairs to a common foot-stalk, which terminates in a single small leaf or foliole. The branches are terminated by spikes of leguminous red flowers, and sometimes white. When the bloom is past, the pistil becomes a small crested pod, rough, and containing a seed like a kidney.

There is another sort of saintfoin that is smaller, and the seeds rougher: the large sort is best. There is also another large sort that comes from Spain, which has very red flowers: this yields a great deal of grass; but hard frosts kill it.

Saintfoin is a very vigorous plant, and yields a great deal of excellent fodder; not so much however as lucerne, because it can only be mowed twice a year; but it has the advantage of lucerne in not being so nice with respect to the soil: it thrives infinitely better in well-manured land, that has a good depth of soil; but it does not do amiss in russet lands, in which lucerne would soon perish: besides, every kind of grain grows well on land that has been in saintfoin.

Land intended for saintfoin has two or three ploughings, that it may be well broke: the stones must be picked off the land, that it may be mowed close. About two thirds of the usual quantity of oats should be sowed with the saintfoin; and, for an arpent of an hundred perches, each twenty-two feet, eight bushels, Paris measure, of seed should be used. The saintfoin mixed with the oats should be sowed in March, and covered with the harrow, as it would not grow if buried too deep. As saintfoin seed is often bad, a little of it should be kept out of the field; and the second year the first crop is cut, which however is not so good as that of the third.

Saintfoin is cut sooner or later according to the use it is to be put to. If it is for sheep, it should be mowed as soon as it is in bloom; if to feed oxen or cows, when the bloom is over; and if for horses, it should be suffered to stand till the seed is partly formed in it, in which state the horses are very fond of it: finally, if it is intended to save the seed, either for sowing, or to give to horses,

U

which

which like it better than oats, or to feed poultry, the saintfoin should not be cut till the greatest part of the seed is ripe. When the seed of saintfoin is to be saved, it should be mowed early in the morning, before the dew is off, or there will be a loss.

Saintfoin of three or four years old is generally cut when the bloom is going off. In the southern provinces they keep the cattle out of it, when they would have a second or third crop: but in the other parts of the kingdom, instead of taking a second crop, they turn their horned cattle into it, and the rather, because after the first crop of saintfoin, seed becomes scarce elsewhere.

Saintfoin has another advantage over lucerne, it being much easier mowed, because the sap, being less viscous, evaporates sooner; and it is of a greener colour when in a dark season it is dried by the wind. If rain falls after saintfoin is cut, the swarths must not be turned till the weather is fine: by this means it will still be green and good. There is another advantage in saintfoin, which is, that though the weather should prove rainy, it may be mowed either before the bloom, whilst it is in bloom, when the bloom is past, or when the seed is ripe, as it is most likely that at some of those periods the weather will prove fine.

It may be imagined, that saintfoin which has perfected its seeds will yield but indifferent fodder: the leaves and flowers being fallen, nothing remains but large stalks, which however horses will eat, the taste being agreeable to them.

Saintfoin when in good order yields a fodder excellent for all kinds of cattle, as has been already noticed, whether it is given green or dry: care however must be taken that they do not eat too much of it, particularly such as do not much work; for instance, most coach-horses.

Though this plant will grow in all sorts of land, except such as is marshy, yet it thrives much best in a good soil: it would therefore be of use to dung it now and then. The vigor of the plants may be increased by allowing the roots a space of soil to extend in, and giving it frequent tillage: for this reason, when we would preserve it for more than nine years, it should be cultivated in rows, in the manner of lucerne; with this difference however, that there may be two rows of saintfoin; and two stirrings to the intervals will be enough. But as saintfoin will thrive in any soil, and prepares land well for wheat or rye, it is seldom preserved long in the same field; therefore the common method of husbandry is in general best for it. It is proper to observe, that two bushels of saintfoin seed will do horses as much good as three of oats.

Saintfoin seed will keep very well when it is put into the barn unthrashed; but when it is thrashed, it must be spread thin in the granary, and often turned, or it will be in danger of heating.

The use of this fodder is not so dangerous to horses as lucerne, or even clover. *Du Hamel's Husbandry.*

SAKER, a small sort of cannon, of which there are three species, extraordinary, ordinary, and middle sized.

SALAMANDER, *Salamandra*, in zoology, a name given by authors to several species of the lizard kind; but the principal are two, the *salamandra aquatica*, the water-newt, and the *salamandra terrestris*.

The *salamandra aquatica* is the two-edged-tail lizard, with four toes on the anterior, and five on the hinder, feet. It grows to about four inches in length, and to the thickness of a man's finger: the back is of a deep shining brown; the belly of a bright and glossy yellow.

The *salamandra terrestris*, or land salamander, is a species of lizard, the tail of which is short, and its colour of a fine black, marked with red spots of a bright and shining glossy appearance.

SALAMANDER'S-BLOOD, among chemists, denotes the redness remaining in the receiver after distilling the spirit of nitre.

SALARY, *Salarium*, a recompence made to a person for his pains or industry about another person's business, as in the case of officers, &c.

SALE, in general, signifies the transferring the property of goods from one to another, upon some valuable

consideration, as where in a bargain one agrees to give another a certain sum of money for such goods, and thereupon gives the seller earnest, which he accepts; this is a perfect sale, and shall bind the buyer and seller.

SALEP, in the materia medica, the root of a species of orchis. See ORCHIS.

This plant, which has six or seven long smooth narrow leaves, is variegated with dark coloured streaks or spots, issuing from the root; and one or two embracing the stalk, which is single, roundish, and striated: on its top appears a long loose spike of irregular, naked, purplish red flowers, consisting each of six petals; one of which is large, cut into three sections, hanging downwards; the others smaller, forming a kind of hood above it, with a tail behind: the root consists of two roundish whitish tubercles, about the size of nutmegs, one plump and juicy, the other fungous and somewhat shrivelled, with a few large fibres at top. It is perennial, grows wild in shady grounds and moist meadows, and flowers in the beginning of May or sooner.

The plump roots or bulbs, the only part directed for medicinal use, have a faint somewhat unpleasant smell, and a viscid sweetish taste. They abound with a glutinous slimy juice, in virtue of which they have been found serviceable, like althea root and other mucilaginous vegetables, in a thin acrid state of the humours and erosions of the intestines. They have been celebrated also for analeptic and aphrodisiac virtues, to which they appear to have little claim.

The substance brought from the Eastern countries under the names of salep, falleb, and serapias, and recommended, like our orchis root, in bilious dysenteries, defluxions on the breast, and as a restorative, appears to be no other than the prepared roots of some plants of the orchis kind, of which different species are said to be taken indiscriminately. The salep comes over in oval pieces, of a yellowish white colour, somewhat clear and pellucid, very hard and almost horny, of little or no smell, in taste like gum tragacanth. The common orchis root, boiled in water, freed from the skin, and afterwards suspended in the air to dry, gains exactly the same appearance: the roots thus prepared do not grow moist or mouldy in wet weather, which those that have been barely dried, are very liable to do: reduced into powder, they soften or dissolve as it were in boiling water into a kind of mucilage; which may be diluted, for use, with a large quantity of water, or with milk.

SALIENT, in fortification, denotes projecting. There are two kinds of angles, the one salient, which are those that present their points outwards; the other re-entering, which have their points inwards.

SALIENT, SALIANT, or SAILLANT, in heraldry, is applied to a lion, or other beast, when its fore-legs are raised in a leaping posture.

SALIC, or SALIQUE-LAW, *Lex Salica*, an ancient and fundamental law of the kingdom of France, usually supposed to have been made by Pharamond, or at least by Clovis, in virtue whereof males are only to inherit. Du Haillan, after a critical examination, declares it to have been an expedient of Philip the Long, in 1316, for the exclusion of the daughter of Lewis Hutin from inheriting the crown. Father Daniel, on the other hand, maintains that it is quoted by authors more ancient than Philip the Long, and that Clovis is the real author of it. This law has not any particular regard to the crown of France; it only imports, in general, that in Salic land no part of the inheritance shall fall to any female, but the whole to the male sex. By Salic lands, or inheritances, were anciently denoted, among us, all lands, by whatever tenure held, whether noble or base, from the succession whereto women were excluded by the Salic law; for they were by it admitted to inherit nothing but moveables and purchases, wherever there were any males.

SALII, in Roman antiquity, priests of Mars, of which there were twelve, instituted by Numa, wearing painted parti-coloured garments and high bonnets, with a steel cuirass on the breast. They were called Salii from *saltare*, to dance; because, after assisting at sacrifices, they went dancing about the streets, with bucklers in the left hand, and a rod in the right, striking musically

musically on one another's bucklers with their rods, and singing hymns in honour of the gods.

SALIVA, *Spittle*, a thin pellucid humour, separated from the arterial blood, by the glands about the mouth and fauces, and conveyed, by proper salival ducts, into the mouth, for several uses.

It consists of a great deal of water or phlegm, and a volatile salt, and some add a sulphureous spirit; and is void both of taste and smell: its uses are very great; it moistens the throat, preserves it from the injuries of the air, and facilitates speech. Being mixed with aliment, it renders swallowing easy, and assists digestion by its aqueous, saline, and oily parts. Some imagine it to do the office of a menstruum, by mixing the oily and aqueous parts of the food more intimately, dissolving the saline parts, and procuring a fermentation in the stomach: but Dr. Drake is of opinion, that were the saliva acrimonious enough for this purpose, it must greatly offend the stomach, especially considering the quantities of it that many swallow, even upon an empty stomach. In hungry persons, says Boerhaave, it is fluid, acrid, and copiously discharged; and in those who have fasted long, it is highly acrid, penetrating, and resolvent. In farinaceous and succulent vegetables, it not only produces a fermentation, but also augments one already begun. It is swallowed not only by brutes, but by human creatures, in a sound state, even when asleep. Too copious an evacuation of it, made voluntarily, produces loss of appetite, bad digestion, and an atrophy. By manducation therefore the saliva is expressed and accurately mixed with the attenuated food; which contributes, first, to the assimilation of the aliments to the nature of the body to be nourished: secondly, to the due mixture of the oleous to the aqueous parts: thirdly, to the solution of the saline parts: fourthly, to fermentation: fifthly, to a change of the taste and smell of the aliments: sixthly, to an augmentation of the intestine motion: seventhly, to a momentaneous relief from hunger; and, eighthly, an application of the sapid parts, though insipid itself. See **CHYLIFICATION**, **MANDUCATION**, **DIGESTION**, &c.

SALIVAL, an epithet applied to the glands and ducts which supply and secrete the saliva.

SALIVATION, in medicine, a promoting of the flux of saliva, by means of medicines, mostly by mercury. The chief use of salivation is in diseases belonging to the glands, and the membrana adiposa, and principally in the cure of the venereal disease, though it is sometimes also used in epidemic diseases, cutaneous diseases, &c. whose crises tend that way. See the articles **Pox**, &c.

A salivation is excited, according to Boerhaave, 1. By washing the mouth with certain liquors. 2. By the slow and protracted mastication of some viscid matter, such as mastich, wax, and myrrh, especially if acrid substances are mixed with these, such as pellitory of Spain, pyrethrum, ginger, and pepper. 3. By drawing into the mouth acrid and irritating vapours, such as those of tobacco, sage, rosemary, marjoram, thyme, and mother of thyme. 4. A salivation is excellently excited by the action of such medicines as produce a gentle but long continued nausea, such as antimony neither entirely fixed nor totally emetic, taken with a small quantity of common vitriol. 5. By such substances as totally dissolve all the parts of the blood, convert it into lymph, and render it fit for a discharge by way of saliva; such as crude quicksilver, cinnabar, a solution of quicksilver in aqua fortis, white precipitate, red precipitate, turbith mineral, and sublimate mercury dissolved: the action of those medicines is promoted by warm fomentations applied to the head, neck, and face. An excessive salivation is lessened or stopped, 1. By a large and continual use of mild and tepid drinks, such as decoctions of mallows and liquorice in milk and water. 2. By allaying the impetus of the humours, by means of mild, oleous, and anodyne emulsions, with a proper addition of diacodium or opium. And, 3. By making a revulsion of the humours to other parts, especially that by stool. But great caution is necessary, lest the impetus of the moved matter, which in this case is always acrid, should rush to other parts, and produce a greater danger.

The regular, safest, and most commodious method of salivation is by mercurius dulcis six times sublimed, given inwardly in the milder pox, &c. or by mercurial unction, when the disease is got into the bones. According to Turner, fifteen grains of mercurius dulcis may be given in a morning, and a like dose at night, with electuary of scordium. After three, four, or five days, with this management, the fauces are observed to inflame, the inside of the cheeks to tumify, the tongue to look white and foul, the gums to stand out, the breath to stink, and the whole inside of the mouth to appear shining and lie in furrows as if parboiled. The patient now refuses nourishment, while all parts of his chaps are so swelled and sore that he cannot chew any solid food, but is forced to take liquids and the softer aliments. They are now frequently sick, and throw up a thin phlegm. The inside of the mouth thus beginning to be wealed, will soon be ulcerated, especially about the salival glands, which empty themselves thereinto. Now it may be proper to desist a day or two, to observe the increase of the ulcers, what sloughs are like to be raised, and what their depth and dimensions are like to prove, from which a near conjecture may be made of the duration as well as quantity of the spitting now begun, and the consistence of the drilling lymph. The salivation thus begun, the patient is to be sometimes refreshed by a little mulled wine. Let his diet be small chicken broth, water-gruel, and panada; his drink small sack-whey, or posset-drink, and a draught of good small beer, with a toast, between whiles; and in case of gripes or a looseness, the white decoction.

Thus, after some days respite, if the patient is hearty, his chaps but little swelled on the outside, and as little sore within, the ulcers not increasing, and the flux inconsiderable, you may give one scruple of mercurius dulcis in electuary of scordium at going to rest, repeating it two or three days following, as you find occasion; or you may vomit him with eight or ten grains of turpeth mineral, in conserve of roses: but if the salivation cannot be raised to any quantity, you must forbear, and purge it off, and give calomel once or twice a week, and purge it off the next day, or two days after. When the spitting goes well forward, it may be left to take its course, till it declines of itself, which in proportion to the ulcers and thickness of the sloughs about the mouth, may happen at the end of twenty-one days, or a month from its first rising; that is, from the time of spitting a pint and a half a day, till it come to three pints or even five pints in twenty-four hours, then it gradually goes off again.

In the more stubborn and rebellious pox, &c. attended with grievous symptoms, such as rotten bones, &c. and the patient has been used to mercurials, or salivated before, then the cure must be attempted with salivation by unction. To this end mix an ounce of quicksilver with three ounces of axungia, of which an eighth part is to be used night and morning, letting the patient rub it with his own hands gently by the fire, beginning with his ancles, up to his shins and knees, all round his joints, and so to his thighs, which are presently after to be covered with yarn-sockings and flannel-drawers; then let him use the remainder of his eighth part about his elbows and shoulders, wiping his hands clean about the glands of his arm-pits, or those of his groin: his body, during the unction, should be screened from the cold with a blanket hung behind him, and then be wrapped up in warm flannel, that is, a flannel shirt, waistcoat, drawers, cap, and muffler. And the same is requisite in the former way, to defend the patient from the cold air. The weak need only to anoint once a day; but those that are strong, may take a fourth part of the ointment, and rub it in at once every night; after which let him get between flannel-sheets or blankets, disposing him to a gentle breathing sweat with a draught of warm posset, mace-ale, or, if very feeble, with a cup of mulled wine. If, when the ointment is divided into four parts, after the third unction, the patient begins to complain of his chaps, you may stay a day or two before you proceed farther; the same when gripes or bloody stools approach. On the other hand, if an ounce or an ounce

and

and a half of quicksilver will not do, give the turpeth, as before directed: and if the spitting declines too suddenly, give a scruple of calomel every day, for two or three times, as you see occasion. When the salivation is going off, the patient may be purged with two or three ounces of the common infusion of senna, and one ounce of the syrup of buckthorn.

To prevent the jaws from being locked up, it is necessary to use a bit of stick, covered with a soft rag, to be held between his backward teeth; and if there should happen an adhesion of the inside of the cheek to the gum, the same is to be carefully divided. If, during the salivation, a blood-vessel burst open, it is to be closed up with a little pellet, covered with powder of alum or vitriol, and dipped in the tinctura styptica: if it happens from the separation of sloughs from the sides of the cheeks, a little oxycerate held in the mouth will do the business. If the patient has been without a stool for some time, give him an emollient clyster of warm milk, sugar, and oil: and if the fauces should suddenly tumify, so as to endanger a suffocation, the most certain relief is to bring the humours downwards by sharp clysters and cathartics.

The patient should be prepared for a salivation by a lenitive purge or two; and if plethoric, he should bleed: likewise bathing in warm water, for some hot, lean, emaciated people, has been found of service. Women should be laid down just after their menstrual flux is over. Temperate weather is the most suitable.

SALIX, the willow, in botany, a genus of plants, the leaves of which are entire; the flower, which is male, and grows on a separate plant, is amentaceous, spiked, and consists of a multitude of stamina. The ovary, which is found only on the female plant, is furnished with a long tube, adorned with four horns, is of a conoidal figure, and constituted in such a manner as to become a spiked fruit, containing a multitude of capsules resembling horns, and gaping by maturity into two parts. These capsules are full of many downy seeds.

There are a great number of species to be found in England, especially of the fallows; as I have been informed by a very judicious basket-maker, there are at least thirty sorts, which they distinguish by name, commonly in use in their trade; and, besides these, there are a great number of mountain willows, which grow upon dry grounds, and are cultivated as underwood, in many parts of England.

All the sorts of willows may be easily propagated by planting cuttings or sets in the spring, which readily take root, and are of quick growth. Those sorts which grow to be large trees, and are cultivated for their timber, are generally planted from sets, which are about seven or eight feet long: these are sharpened at their larger end, and thrust into the ground by the sides of ditches and banks, where the ground is moist; in which places they make a considerable progress, and are a great improvement to such estates; because their tops will be fit to lop every fourth or fifth year. The larger wood, if found, is commonly sold for making wooden heels, and pegs for shoes; as also to the turners, for many kinds of light wares.

The fallows are commonly planted in cuttings made from strong shoots of the former year, and are about three feet long; these are commonly thrust down two feet deep into the ground, and are one foot above it. The soil should always be dug or plowed before they are planted, and the cuttings placed about three feet row from row, and eighteen inches asunder in the rows; observing always to place the rows the sloping way of the ground, especially if the tides overflow the place; because, if the rows are placed the contrary ways, all the filth and weeds will be detained by the plants, which will choke them up.

The best season for planting these cuttings is in February; for, if they are planted sooner, they are apt to peel, if it proves hard frost, which greatly injures them.

These plants are always cut every year; and, if the soil be good, they will produce a great crop, so that the yearly produce of one acre has been often sold for fifteen pounds; but ten pounds is a common price, which is much better than corn land; so that it is great pity

these plants are not more cultivated, especially upon moist boggy soils, upon which few other things will thrive.

SALLET, or **SALLAD**, a dish of eatable herbs, ordinarily accompanying roast meat, composed chiefly of crude fresh herbage, seasoned with salt, oil, and vinegar; some add mustard, hard eggs and sugar; others pepper; and others spices, with orange-peel, saffron, &c. The principal sallet-herbs, and those which ordinarily make the basis of our sallets, are lettuce, celeri, endive, cresses, raddish and rape; to which are sometimes added purslane, spinach, sorrel, tarragon, burnet, corn-sallet, and chervil.

SALLY, in architecture, is what we more usually call projecture. See **PROJECTURE**.

SALLY, in the military art, the issuing out of the besieged from their town or fort, and falling upon the besiegers in their works, hinder the progress of their approaches, destroy their works, &c.

SALMO, **SALMON**, in ichthyology, a well known fish. It is distinguished from other fish of the truttaceous kind by these characters: it is of an oblong body covered with very small scales, a small head, a sharp nose, and a forked tail. Its back is bluish; the rest of its body whitish, or reddish, and usually spotted. Its under jaw is bent upwards, and that sometimes so much as to make itself a sinus in the upper, by constant motion, and sometimes to perforate it.

The salmon is first produced from its parent's spawn in fresh rivers, thence it goes into the sea to acquire its growth and feed, and, at the time of its full growth, and in the season for spawning, it removes into the fresh waters again.

The salmon, in the different stages of its life and growth, has different names. The Latins call it, when young, *salar*, when of a middle growth *sario* or *fario*, and only when full grown *salmo*. In England the fishermen have names for it in every year of its growth. In the first it is called a smelt, in the second a sprod, in the third year a mort, in the fourth a fork-tail, in the fifth a half-fish, finally, in the sixth it is called a salmon. This is the common agreement of our fishermen, though there are some who say the salmon comes much sooner to its full growth. *Willughby's Hist. Pisc.*

The salmon is bred in rivers, but goes every year from thence into the sea; and at a certain season of the year it always returns up into the fresh water again; and what is remarkable, is, that, so far as observation has been able to trace them at any time, the same shoals of salmon always return into the same river out of which they swam, not into any other; so that the people who live on the salmon fishery are not afraid for their rivers being cleared, by all the fish in them going down into the sea, for they know that they will all return up to them again at a proper time. When the salmon has once entered a fresh river, he always swims up against the stream, and often will go an hundred leagues up a river in the large and long rivers; and the people at this vast distance from the mouth have the pleasure of taking a fish, that is properly in part of the sea kind. It is also remarkable, that the rivers which most abound with salmon do not make the seas about their mouths, any more abound with them than others, particularly the harbour of Brest affords no salmon; though the river Chateaulin, which discharges itself into it, is the richest salmon river in France.

Another singularity, in regard to the salmon, is their swimming up the rivers together in such vast numbers. It is to be allowed, indeed, that herrings, mackarel, and many other fish, do in the same manner appear on the coasts at certain seasons, in prodigious numbers; but the reasons for their coming together, in these quantities, are much more easily explained than that of the salmon's doing so. The herrings, when they come in such prodigious shoals to the coasts of Normandy, have been found to be allured thither in these numbers by a prodigious quantity of a particular sort of sea worms, which are their favourite food, and which are found to cover the whole surface of the sea at that time. Rondeletius has described these insects under the name of sea caterpillars; they always appear in the months of June, July, and August, which are the herring seasons at that part of the world;

world; and probably the same cause will be found to bring them to other places, if sufficiently enquired into, as these and some other fish come to certain places in shoals to get food. The salmon do it, in order to propagate their species. The spawn of the salmon is never deposited but in rivers, and, at the time that these fish are found up the rivers, it is only with this intent; the females go first, and the males follow as far as the others please to lead them, which is usually to some convenient place in shallow water, where the spawn, when deposited, is not buried under too great a quantity of water, but has the advantage of a continual warmth from the sun's heat.

Salmon do not equally frequent all rivers, though they may seem to us equally proper for their reception. There are two rivers which open themselves into the harbour of Brest, very near one another; the one of these is famous for the quantity of salmon in it, and the great advantage of the fishery; the other never has any of these fish in it. It most probably is owing to their finding plenty of food, and proper places for the depositing their spawn in the one of these rivers, and not in the other, that makes this regular choice. *Des Landes, Trait. Phys.*

SALON, or **SALOON**, in architecture, a very lofty spacious hall, vaulted at top, and sometimes comprehending two stories or ranges of windows. The salon is a grand room in the middle of a building, or at the head of a gallery, &c. Its faces or sides ought all to have a symmetry with each other; and as it usually takes up the height of two stories, its ceiling, as Daviler observes, should be with a more moderate sweep. Salons are frequently built square, and sometimes octagonal.

SALT, *Sal*, in natural history, the name of a series or subdivision of fossils, naturally and essentially simple, not inflammable, and soluble in water.

Dr. Shaw defines salt to be a substance that readily dissolves in water, tastes sharp or pungent upon the tongue, and has a great disposition to unite with earth, so as to appear in a solid form; as in common salt, alum, &c.

Salts then are fossil bodies, friable, pellucid, not inflammable, but fusible by fire, and congealing again in the cold; soluble in water, so as to disappear in it, naturally concreting into regularly figured crystals, and impressing a sensation of acrimony on the tongue. These are the characters and qualities common to all salts, and to no other bodies: and these they always manifest when pure and freed from heterogeneous substances; but in the state in which they are naturally found in the earth, though they have that in their taste alone which may sufficiently distinguish them, yet they do not exhibit all their genuine characters: some of them being found solid and pure, either within the earth or on its surface, but commonly without their proper form; others embodied in earths and stones, as the particles or metals in their ores; and others in a fluid state suspended in waters.

Of the fossils of this class, nature therefore affords us three distinct orders, and under those they are distinguishable into five genera. The salts of the first order are those found native and pure, either in the earth or without its surface, and exhibiting all other natural characters, though often without their proper form.

Of the second, are those found not native, but in form of ores, never pure, but distinguishable by their taste, and immersed in and blended with the constituent matter of earths and stones in extremely small particles. And of the third are those naturally found suspended in waters, and in a fluid form, but ready to assume their proper figures on the evaporation of a part of that water.

Of the first of these orders are the common alimentary salt or muria, and the natrum or nitre of the ancients; of the second are alum and nitre; and of the third are borax and halcryptium, an alkaline salt hid in the chalybeate waters.

Alimentary salt, or muria, is found under a great variety of forms in its different states; but is immediately distinguished by applying it to the tongue, and always assumes a cubic, pyramidal, or parallelopiped figure after solution, and a regular crystallization. It is sustained in vast quantities in a liquid form among sea-water, and that of salt springs; but is also found solid in the bowels of the

earth in vast masses, which are either of a fine pellucid structure, and called sal-gem; or various, debased, and striated, resembling the fibrose tales, and is the sal ammoniac of the ancients.

But in which ever of these forms this salt is found, it affords the same crystals on evaporation: these, according to the degree of heat used in the evaporation, are either pyramidal, cubic, or parallelopiped. All these salts are soluble in water; but they require different quantities of it to dissolve them, and this makes one of their criterions. This salt requires thrice and one seventh part its own quantity of water, to make a perfect solution.

The sea-water, in different parts of the world, is very differently sated with it, some parts containing twice as much as others. But that of the salt-springs is always much more salted with it, than the strongest of the sea-water: in some places it is found loaded with nearly as much as it could be made to contain, some springs yielding a brine that affords near a quarter of a pound of salt, from the pound weight of this liquor, and many of them being so strongly impregnated, that the workmen are obliged to let them down or lower them, by mixing them with a large quantity of sea or common water, before they are fit to be boiled for the salt: the common run of sea-water does not hold so much as one fourth part of this quantity, some not one eighth of it.

The salt produced from the sea-water of all the parts of the world, and from the brine of all the springs of the world, is absolutely the same; but differs in strength, and some other qualities, according to the operation by which it is made. In general, the quicker the liquor is evaporated, the weaker is the salt; the more time is employed in the process, the stronger. This is not wonderful, when we consider, that, over a gentle heat, water alone, or almost alone, evaporates from the liquor, but over a more violent fire, a part of the strength or acid of the salt is raised with it.

It is upon this principle, and owing to this cause, that we find the salt of our salt springs, which is usually sold us under the name of basket-salt, the weakest of all. It is not that there is any difference in the waters from which these several kinds of salt are produced, that they appear to us in different degrees of strength, but that the people who work the brine-pits, make the salt with less expence of the workman's time; that the sea-salt is formed over somewhat slower fires; and that the bay-salt is made only by the sun's heat, where the process is very long, and the heat very moderate, and the salt is found strong in proportion. This is so indisputable a truth, that once every week, a very strong salt, little inferior to bay-salt in that quality, is made at the brine-pit works, where the common run of the salt is the weakest in the world. The liquor is the same in this case, but the workmen who do not work on Sundays, leave a pan full to evaporate slowly over the fire, which they prepare on the Saturday night, and the moderate heat and length of time under which this weekly parcel of salt is made, render it very different from the common salt of the works, both in form and qualities: it is found to be made up of large and hard grains, instead of the small and soft ones of the common kind, and is vastly superior to it in strength.

This circumstance, overlooked by the workmen, and even by their masters too, for many years, gave the hint to Mr. Lownd, and afterwards to the very ingenious Dr. Browning, author of an excellent treatise on this subject, to propose to the government a method of making a salt fit for all the purposes for which we buy it of our neighbours, only by a new, that is, a slower way of working our own brines. The latter of these gentlemen has proved, incontestably, that we may, if we will encourage proper manufactures, have common salt of every kind made at home, equal in strength, and equally fit for all purposes, with the salt of any part of the world.

After these accounts of the muria of common salt under its different forms, and as expressed by different names, it remains to treat of its qualities and virtues in general.

It resolves spontaneously in the air, but this in different times, according to the dampness or dryness of that element, and according to its own laxer or firmer structure. The coarser salts dissolve sooner than the finer,

and there are even some pieces of sal gemmæ so firm, that they are scarce to be at all affected, even on their surface, by the moistest common air.

Common salt, added to aqua fortis, enables it to dissolve gold, making it into what is called aqua regia; by distillation it yields a strong and acid spirit; it is the most of all substances, endued with keeping animal bodies from putrefaction, and it also preserves vegetables in the same manner in long digestions. In medicine, it is a common ingredient in clysters, and serves to soften and bring away indurated fœces. Suppositories are also made of a mixture of it with honey, and are put up the fundament, to promote a tendency to desiccations. Aloes and colocynth are sometimes added on these occasions, when there is required more power in the medicine. In apoplectic cases, it is generally an ingredient among the stimulating things administered in clysters; only it is necessary to have this caution, that if there appear reason to suspect an inflammation of the intestines, or but a tendency to it, every thing of this kind is to be avoided.

Common salt that has not been exposed to a fire, makes no change in the colour of syrup of violets; it does not make any effervescence with oil of tartar, nor does it make lime-water turbid, but added to spirit of sal armoniac, it manifests some signs of a latent acidity, by rendering it cloudy: on the contrary, also, it manifests something of an alkaline nature, by rendering a solution of mercury whitish; and it raises an effervescence with oil of vitriol, attended with heat.

On solution in water, common salt manifests also two very different principles after evaporation. When reduced to a proper consistence, that is, when the quantity of water is not more than as three to one to that of the salt, a part of it concretes into grains of salt of the ordinary kind; but there remains yet in the liquor, after all that can be separated this way has been procured, a strong taste of a saline nature; the salt that gives it this, will never be brought to crystallize, but must be separated by evaporating all the liquor away; it is then found to be of an alkaline nature, assuming no regular form in its crystals, and easily imbibing the humidity of the air, and running into a liquor with it.

The basis of sea-salt, therefore, is a mineral alkali, which is so intimately blended with its peculiar acid, that the latter has scarce any power of exerting itself.

The acid, drawn by distillation from sea-salt, turns the syrup of violets red, and ferments vehemently, though without heat, with oil of tartar; but it does not heat on being poured into lime-water. This spirit is the only one that can be properly called a solvent for gold and for tin, but silver and lead resist it. The acids of nitre and vitriol, also, obtain the same qualities on being mixed with it, and become aquæ regales. If this acid be perfectly saturated with salt of tartar, crystals of the form and qualities of those of common salt may be obtained from the mixture; these crystals are called regenerated sea-salt, and serve to prove what we observed above, that an alkali is the basis of sea-salt, and that more alkalies than one may serve to that purpose with the peculiar acid, which is the essential part of this salt.

Physicians are of opinion, that sea-salt has the same effects in the human body that it has out of it, in checking fermentation, and preventing putrefaction; they therefore esteem it of good use mixed with the generality of our foods in the stomach: they are of opinion also, that it carries its effect into the blood, and has the qualities of a moderate dryer, detergent and attenuant, added to those of a stimulant, which common reason declares it to be. Hence may be deduced all the virtues attributed to salt, as an aperient, stomachic, or warming medicine, and a provocative to venery; but in what degree it possesses all these qualities, we are, by its universal use in foods, prevented from being able to determine. Van Helmont recommends it as a good preservative against the stone and gravel: he has been severely censured for this by others, who are of opinion, that all salted foods, such as salt beef, and the like, are very bad in those cases: but both parties may be in the right; for there is a great deal of difference between common salt eaten with the fresh juices of our food, and the brine and pickle into which it runs in the time of its being left upon the meat preserved

by it. Salt is very properly put into the mouths of people in apoplectic fits, as it not only irritates but attenuates the juices there, and promotes a discharge of them; and in a palsy which affects the tongue, a sage-leaf, bruised and covered with salt, has been a famous remedy among the good women, and not without reason.

Mixed with bran, and heated in a canvas bag, it is recommended to be applied externally to the head in head-achs, arising from a moist cause, and in defluxions; and we find the old physicians very strenuously recommending a cataplasm made of the same ingredients for pains.

Methods of making alimentary SALT are these: 1. By the evaporation of the sun's rays: this is the most easy and simple method of all, when the water of ponds and lakes, whether natural or artificial, impregnated with salt, being wholly exhaled by the force of the sun and air, the salt is concentered into a hard crust at the bottom of the lake, and is what commonly goes by the name of bay-salt; the crystals of which differ in size, according to the different degrees of heat, and the time it lies in the pits. All bay-salt has some mud, slime, or the like, in the making, and some kinds are mixed with the bitter-salt, or what is called Epsom salt; they are all more white while dry, and more pellucid when moist, and they differ in colour, according to the earth which makes the bottoms of the pits. Thus, some of the French bay-salt is grey, some reddish, and some white, according as a blue clay has lined the pits, or a red, or white one. Some kinds have an agreeable smell in large heaps; such are the Portugal, and the Hampshire bay-salts; and this seems owing to the sea-water they were made from, having a bituminous matter in it. It differs also greatly in taste, according to the various foreign mixtures it contains; and it will often alter in taste, and other qualities, by long keeping: for, in general, it is much fitter for use, after it has been kept some time in a dry place, than when it is first made.

2. By boiling, or coction, the most convenient works for which process are constructed in the following manner: the saltern or boiling house is erected near the sea-shore, and is furnished with a furnace and one or two large pans, which are commonly made of iron plates, jointed together with nails, and the joints filled with a strong cement; and the bottoms of the pans are prevented from bending down, by being supported by strong iron-bars.

The salt pan being filled with sea-water, a strong fire of pit coal is lighted in the furnace, and then, for a pan which contains about fourteen hundred gallons, the salt-boiler takes the whites of three eggs, and incorporates them all with two or three gallons of sea-water, which he pours into the salt pan, while the water contained therein is only lukewarm, and mixes this with the rest by stirring it about with a rake. In many places they use instead of eggs the blood of sheep or oxen to clarify the sea-water; and in Scotland they do not give themselves the trouble of clarifying it at all. As the water heats, there arises a black frothy scum upon it, which is to be taken off with wooden skimmers. After this, the water appears perfectly clear, and, by boiling it briskly about four hours, a pan loaded in the common way, that is about fifteen inches deep, will begin to form crystals upon its surface. The pan is then filled up a second time with fresh sea-water; and, about the time when it is half filled, the scratch pans are taken out and emptied of a white powder, seeming a kind of calcareous earth, which separates itself from the sea-water, during its boiling, before the salt begins to shoot. When these have been emptied, they are again put into their places, where they are afterwards filled again. This powder, being violently agitated by the boiling liquor, does not subside till it comes to the corners of the pan, where the motion of the mass is smaller, and it there falls into these pans placed on purpose to receive it.

The second filling of the pan is boiled down after clarifying in the same manner as the first, and so a third and a fourth; but in the evaporation of the fourth, when the crystals begin to form themselves, they slacken the fire, and only keep the liquor simmering. In this heat they

they keep it all the while that the salt is granulating, which is nine or ten hours. The granules or crystals all fall to the bottom of the pan; and when the water is almost all evaporated, and the salt nearly dry at the bottom, they rake it altogether into a long heap on one side of the pan, where it lies a while to drain from the brine, and then is put into barrows, and carried to the store-house, and delivered into the custody of his majesty's officers. In this manner the whole process is usually performed in twenty-four hours, the salt being commonly drawn out every morning. This is the method in most of our salt works, but in some they fill the pan seven times before they boil up the salt, and so take it out but once in two days, or five times in a fortnight. In the common way of four boilings, a pan of the usual size, containing one thousand three-hundred gallons, they draw from fifteen to twenty bushels of salt every day, each bushel weighing fifty-six pounds.

When the salt is carried into the store-house, it is put into drabs, which are partitions, like stalls for horses, lined at three sides, and the bottom with boards, and having a sliding-board on the fore-side to draw up on occasion. The bottoms are made shelving, being highest at the back, and gradually inclining forwards; by this means the brine, remaining among the salt, easily separates and runs from it, and the salt in three or four days becomes sufficiently dry; in some places they use cribs and barrows, which are long and conic wicker-baskets for this purpose, and in some places wooden troughs with holes in the bottom. The saline liquor which remains after the making of salt is what is called bittern.

Much in the same manner is the salt obtained from the brine of salt springs, pits, &c. White salt is prepared from sea water, or any other kind of salt-water, first heightened into a strong brine by the heat of the sun, and the operation of the air. It may also be prepared from a strong brine, or lixivium, drawn from earths, stones, or sands, strongly impregnated with common salt. Refined rock salt is that obtained by dissolving fossil or rock-salt in salt of fresh water, and afterwards boiling the solution. And, lastly, salt upon salt is made from bay-salt dissolved in sea-water, or other water, and boiled to a white salt.

SALT, in chemistry, makes one of the leading and most active principles, or elements, procurable from mixed bodies.

There are three kinds thus obtained, two of which are volatile, and the third fixed. The volatile, are acid and urinous salts; the fixed, lixivious, or those drawn from ashes: the urinous and lixivious salts are also called alkalies, or alcalious salts; the former being volatile, and the latter fixed.

Acid salts are ranged, by Homberg, under three classes, viz. such as contain an animal or vegetable sulphur; as all the acids distilled from plants, fruits, woods, &c. and spirit of nitre: such as contain a bituminous sulphur; to which belong the acids of vitriol, common sulphur, and alum: and such as contain a more fixed mineral sulphur; as the acids drawn from the sea-salt, and sal-gem. Those of the first class act more swiftly than those of the others, and those of the second are the least nimble. Acid salts, joined with lixivious ones, compose mixed or intermediate salts: thus, spirit of nitre, with salt of tartar, produce a true salt-petre; spirit of salt, with salt of tartar, produce true common salt; and spirit of vitriol, with salt of tartar, produce true vitriol; which are all mixed or intermediate salts, i. e. partly fixed and partly volatile, the ingredients still retaining their original natures. Acids, joined with urinous salts, compose another salt called ammoniac salts, which are always volatile.

In all native salts, both fossil, vegetable, and animal, after the violence of the fire has separated all the volatile parts, there still remains a fixed salt, to be drawn from the *foeces* by lotion, or lixiviation; hence called a lixivious salt, which is no other but the relics of the acid salts, that the fire was not able to separate from the earth of the mixed body, but may be separated by dissolving them in common water. The taste of these lixivious salts is very different, according to the quantity of the acids still remaining after calcination; part of which is still capable of being volatilized by a more intense heat, or by dis-

solution, digestion, filtration, and evaporation frequently repeated; or, by adding some urinous salt, to absorb the same.

We have three sorts of urinous salts, viz. that of plants or animals, which is the same; the second is fossil; and the third of an intermediate kind, partaking both of the fossil and vegetable nature; the first is volatile, and the two latter fixed. By urinous salts, we mean all such as partake of the taste or smell of urine; their effect in volatilizing fixed salts is well known; for being added to common salt, there arises, by fire, a volatile salt, called sal ammoniac. However, for volatilizing the fixed salts of plants, the urinous salts of plants are not so proper as the urinous salts of the intermediate class, such as alum; and for the fixed salts of fossils, the urinous salt is fittest, viz. borax.

All the sorts, then, appear evidently compounded and unelementary; and that they are producible *de novo*, and convertible into one another, is strenuously argued by Mr. Boyle. The two chief qualities wherein they all agree, he observes, are to be easily dissoluble in water, and to affect the palate, so as to cause a sense of taste. Now that a disposition to be dissoluble in a liquor, may be acquired by mixture, and a new texture of parts, appears from many instances; and as for the taste, it is some question, how far the necessity thereof may consist with another principle; for the purest oils are sapid, yet will not dissolve in water; so that there does not appear any strict connection between being sapid and soluble in that fluid.

For acid salts, we may instance in nitre: which, though it have no acid taste, may be made to afford by distillation, above three quarters of its weight, of a highly acid liquor; yet it does not appear, that such a great proportion of acid particles, or possibly any proportion at all, is employed by nature in the composition of nitre.

For urinous salts, we have an instance of their production, in the salt obtained by distillation from foot: for though the wood we burn in our chimneys, seems to have nothing of the taste or smell of urine, nor have the dissolutions of the saline parts of such wood been observed to have any affinity, in taste or odour, thereto; yet when wood is burnt in the fire, and the foot afforded by it distilled, we get a white volatile urinous salt, like what is obtained from blood, urine, or the like.

For lixivious, or the fixed salts of calcined bodies, the chemists themselves are not entirely agreed; for however the prevailing opinion may be, that those fixed alkalies pre-exist in mixed bodies, Helmont very ingeniously proposes another origin, and holds them, as to their alkaline form, productions of the fire, by whose violent action a part of the salt, which in the concrete is all naturally volatile, laying hold of some parts of the sulphur of the same body, both become melted together, and thus fixed into an alkali.

It would, no doubt, contribute greatly to the improvement of chemistry, and natural philosophy, to form a table of the time and quantity wherein all the known salts are dissoluble in water. Epsom-salt presently dissolves in about an equal quantity of water; common salt dissolves in about four times; nitre, in about five or six times; and salt of tartar, in about twice its own quantity of boiling water, to dissolve it. Such a table, regularly formed, might ease the trouble of refining salts; by shewing, at once, how much water each salt requires to dissolve it, for clarification, or crystallization. It would likewise supply us with a ready and commodious way of separating any mixture of salts, by shewing which would shoot out of the mixture first upon crystallization; for the rule is, that the salt which requires the largest proportion of water to dissolve it, will shoot the first; and thus it is, that nitre is totally separated from common salt, in the ordinary process for refining it.

The same table might also direct us to a ready method of separating two salts, without waiting for crystallization; thus, suppose tartar of vitriol were mixed with Epsom salt, if water be poured upon the mixture, it will presently drink in the Epsom salt, leaving the tartar of vitriol untouched; and the same is to be understood of other mixtures of salts.

If, says Dr. Shaw, the physical reason be demanded, why one salt more readily dissolves in water than another, we recommend it to farther examination, whether all salts do not dissolve in water with greater or less facility, and in greater or less proportion, according as they contain more or less of a gross, unctuous substance, unsuitable to the nature or fineness and lubricity of parts required in water. The comparing Epsom salt, salt of tartar, common salt, &c. with nitre, alum, crude tartar, &c. he thinks will make this more than a conjecture. Hence, in order to lessen the trouble and expence of procuring the volatile salt of animal subjects, they should be first purged of their oil and unctuous parts, by boiling in water; after which, they will afford volatile salts and spirits, as pure, or purer, than those obtained from unboiled hartshorn.

The same gentleman observes farther, that the unrectified volatile salts of vegetable and animal substances, are true sales volatiles oleosi; and according to the difference of the oil wherein they abound, they are properly distinguished into salt of hartshorn, of ox-bone, of human blood, of silk, &c. But that when these oils are totally separated from them, they become one and the same undistinguishable volatile salt; for that it is the admixture of oil that gives the colour to volatile salts, they being permanently white when the oil is separated.

These volatile salts are obtainable from all kinds of land animals, the amphibious and subterraneous tribe, birds, fishes, and reptiles; also from alkaline vegetables without putrefaction, and from other vegetables after putrefaction; from soot, horns, hoofs, and all refuse animal and vegetable matters, as urine, the blood of slaughter houses, &c. and this as pure and perfect as from hartshorn; whence volatile alkalies, and sal ammoniac, might be afforded very cheap.

The volatile animal, and fixed vegetable salts, differ chiefly with regard to their volatility, and fixedness, and the effects thereon depending; but agree in other respects: thus they both make an effervescence, and turn neutral, when saturated with acids; they are corrosive, hot, and fiery, &c.

SALTIER, in heraldry, an ordinary in form of a St. Andrew's cross; which may be said to be composed of a bend dexter and sinister, crossing each other in the center of the escutcheon.

SALT PETRE, the same with nitre. See the article **NITRE**.

SALVAGE MONEY, a reward allowed by the civil and statute law, for the saving of ships or goods from the danger of the seas, pirates, or enemies.

Where any ship is in danger of being stranded, or driven on shore, justices of the peace are to command the constables to assemble as many persons as are necessary to preserve it; and, on its being preserved by their means, the persons assisting therein shall, in thirty days after, be paid a reasonable reward for the salvage, otherwise the ship or goods shall remain in the custody of the officers of the customs, as a security for the same.

SALVATELLA, in anatomy, a branch of the axillary vein, which runs over the back of the hand towards the little finger.

SALUTATION, the act of saluting, greeting, or paying respect and reverence to any one.

There is a great variety in the forms of salutation. The orientals salute by uncovering their feet, laying their hands on their breasts, &c. In England, we salute by uncovering the head, bending the body, &c. The pope makes no reverence to any mortal, except the emperor, to whom he stoops a very little, when he permits him to kiss his lips. A prince, or person of extraordinary quality, is saluted at his entering a garrison by the firing of the cannon round the place. In the field, when a regiment is to be reviewed by a king, or general, the drums beat, as he approaches, and the officers salute him one after another, as he passes by, stepping back with the right foot and hand, bowing their spontons to the ground, and then recovering them gently, bringing up the foot and hand, planting them; which done, they pull off their hats without bowing. The ensigns salute all together, bringing down their colours near

the ground directly before them at one motion, and having taken them up again, gently lift their hats.

At sea, they salute by a discharge of cannon, which is greater or less, according to the degree of respect they would shew; and here ships always salute with an odd number of guns, and galleys with an even one. To salute with muskets is to fire one, two, or three volleys; which is a method of salutation that sometimes precedes that of cannon, and is used on occasion of feasts. After the cannon, they also sometimes salute or hail with the voice, by a joint shout of all the ship's company, repeated three times; which salutation also occasionally obtains where they carry no guns, or do not care to discharge any. Saluting with the flag is performed two ways, either by holding it close to the staff so as it cannot flutter, or by striking it so as it cannot be seen at all, which is the most respectful. Saluting with the sails is performed by hovering the top-sails half-way of the masts. Only those vessels that carry no guns salute with the sails.

SAMARITANS, an antient sect among the Jews, still subsisting in some parts of the Levant, under the same name.

Its origin was in the time of Rehoboam, under whose reign the people of Israel were divided into two distinct kingdoms, that of Judah and that of Israel; the capital of the latter being Samaria, the Israelites obtained the name of Samaritans.

They were antiently guilty of idolatry, and the rabbins pretend, that they worshipped the figure of a dove on mount Gerizim; but the present Samaritans, who are but few in number, are far from being idolaters. They celebrate the passover every year, on the fourteenth day of the first month, on mount Gerizim, and begin that feast with the sacrifice appointed for that purpose in Exodus: they keep the sabbath with all the rigour with which it is enjoined in the book of Exodus, none among them stirring out of doors but to the synagogue; they sacrifice no where but on mount Gerizim: they observe the feasts of expiation, tabernacles, harvest, &c. and never defer circumcision beyond the eighth day; they never marry their nieces as the Jews do; have but one wife; and, in fine, do nothing but what is commanded in the law.

SAMARITAN MEDALS, some antient medals in the cabinets of our antiquaries, the inscriptions and legends of which are in Hebrew; but the character different from the Hebrew of our Bibles, which is the square Hebrew, or Chaldee; from this character, and not from their being struck by the Samaritans, they are denominated Samaritan.

Of these there are four kinds: the first bear expressly the name of Simon, and the subject for which they were struck, viz. the deliverance of Jerusalem. The second have not the name Simon, but only the deliverance of Sion or Jerusalem. The third, have neither Simon, nor the deliverance of Sion; but only the epochas, first year, second year, &c. The fourth class have neither any inscriptions, nor any thing whence we may judge of the time when they were struck. The three first were certainly struck by the Jews, after their return from the Babylonish captivity, and in the time of Simon Maccabeus, after Jerusalem had been freed from the yoke of the Greeks; but though they were struck after the captivity, the learned jesuit Souciet observes, that their character shews itself to be that of the antient Hebrew, the use of which was lost by the people during their sojourn in Babylon and Chaldaea; but was again restored after their return, on the same footing as before.

SAMBUCUS, the *Elder*, in botany, a genus of plants, the flower of which consists of a single rotated semiquinquefid petal; its fruit is a roundish unilocular berry, containing three seeds, convex on one side and angulated on the other.

The inner green bark of this shrub is gently cathartic: an infusion of it in wine, or its expressed juice, in the dose of half an ounce, or an ounce, is said to purge moderately; and in small doses, to prove an efficacious deobstruent, capable of promoting all the fluid secretions. The young buds, or rudiments of the leaves, are strongly purgative, but are reckoned unsafe. The expressed juice,

spissated to the consistence of a rob, proves an useful aperient medicine, which is good in obstructions of the viscera, and promotes the natural evacuations.

SAMBUCUS is also an antient musical instrument of the wind-kind; resembling a flute; probably thus called, because made of elder.

SAMIAN EARTH, in the materia medica, the name of two species of marl used in medicine, viz. 1. The white kind, called by the antients, collyrium Samium; being astringent, and therefore good in diarrhæas, dysenteries, and hæmorrhages; they also used it externally in inflammations of all kinds. 2. The brownish-white kind, called after Samius, by Dioscorides; this also stands recommended as an astringent.

SAMOSATENIANS, in church-history, the same with Paulianites. See the article PAULIANITES.

SAMPSEANS, in church-history, an antient sect, who were properly neither Jews, Christians, nor Gentiles, though they took their name from the Hebrew word *Semes*, sun; as though they worshipped that planet.

They acknowledged only one God; washed themselves often; and in almost every thing attached themselves to the religion of the Jews. Many among them abstained wholly from eating of flesh. Scaliger will have the Sampseans to be the same with the Esseni; and, indeed, the Sampseans, Esseni, Alcesaites, and Massalians, appear to be no more than so many different names for the same sect.

SANBENITO, or SAGO BENITO, a kind of linnen garment worn by persons condemned by the inquisition. See the articles INQUISITION and *Act of FAITH*.

SANCTIFICATION, the act of sanctifying, or rendering a thing holy.

The reformed divines define sanctification to be an act of God's grace, by which a person's desires and affections are alienated from the world, and by which he is made to die to sin, and to live to righteousness; or, in other words, to feel an abhorrence of all vice, and a love of virtue and religion.

SANCTION, the authority given to a judicial act, by which it becomes legal and authentic.

SANCTUARY, among the Jews, also called Sanctum Sanctorum, or holy of holies, was the holiest and most retired part of the temple of Jerusalem, in which the ark of the covenant was preserved, and into which none but the high priest was allowed to enter, and that only once a year, to intercede for the people.

Some distinguish the sanctuary from the sanctum sanctorum, and maintain that the whole temple was called the sanctuary.

To try and examine any thing by the weight of the sanctuary, is to examine it by a just and equal scale; because, among the Jews, it was the custom of the priests to keep stone weights, to serve as standards for regulating all weights by, though these were not at all different from the royal, or profane weights.

Sanctuary, in the Romish church, is also used for that part of the church in which the altar is placed, inclosed with a rail or ballustrade.

SANCTUARY, in our antient customs, is the same with asylum. See ASYLUM.

SAND, *Arena*, in natural history, a genus of fossils, the characters of which are, that they are found in minute concretions; forming together a kind of powder, the genuine particles of which are all of a tendency to one determinate shape, and appear regular, though more or less compleat concretions; not to be dissolved or disunited by water, or formed into a coherent mass by means of it, but retaining their figure in it; transparent, vitrifiable by extreme heat, and not dissoluble in, nor effervescent with, acids. Sands are subject to be variously blended both with homogeneous and heterogeneous substances, as that of talcs, &c. and hence, as well as from their various colours, are subdivided into, 1. White sands, whether pure or mixed with other arenaceous or heterogeneous particles; of all which there are several species, differing no less in the fineness of their particles, than in the different degrees of colour, from a bright and shining white, to a brownish, yellowish, greenish, &c. white. 2. The red and reddish sands, both pure and impure. 3. The yellow sands, whether pure or mixed, are also

very numerous. 4. The brown sands, distinguished in the same manner. 5. The black sands, whereof there are only two species, viz. a fine shining greyish black sand, and another of a fine shining reddish-black colour. 6. The green kind, of which there is only one known species, viz. a coarse variegated dusky green sand, common in Virginia.

Sand is of great use in the glass-manufacture; the white writing sand being employed for making of the white glass, and a coarse greenish-looking sand for the green glass.

In agriculture, it seems to be the office of sand to make unctuous earth fertile, and fit to support vegetables, &c. For earth alone, we find, is liable to coalesce, and gather into a hard coherent mass, as appears in clay; and being thus embodied, and as it were glued together, is no way disposed to nourish vegetables. But if such earth be mixed with sand, its pores are thereby kept open, and the earth itself loose, so as thus to give room for the juices to ascend, and for plants to be nourished thereby. A vegetable planted only in sand, or in a fat glebe, or in earth, receives little growth or increase; but a mixture of both renders the mass fertile. In effect, earth is in some measure made organical by means of sand; pores and spaces, something analogous to vessels, being thereby maintained, by which the juices may be conveyed, prepared, digested, circulated, and at length discharged.

Common sand is a very good addition, by way of manure, to all sorts of clay-lands; it warms them, and makes them more open and loose. The best sand for the farmer's use is that which is washed by rains from roads or hills, or that which is taken from the beds of rivers; the common sand that is dug in pits never answers nearly so well. However, if mixed with dung, it is much better than laid on alone: and a very fine manure is made by covering the bottom of sheep folds with several loads of sand every week, which are to be taken away, and laid on cold stiff lands, impregnated as they are with the dung and the urine of the sheep.

Beside clay-land there is another sort of ground very improveable by sand; this is that sort of black foggy land on which bushes and sedge grow naturally, and which they cut into turf, in some places. Six hundred load of sand being laid upon an acre of this land, according to the Cheshire-measure, which is near double the statute-acre, meliorate it so much, that without plowing, it will yield good crops of oats or tares, though before it would have produced scarce any thing. If this crop is taken off, the land be well dunged, and laid down for grass, it will yield a large crop of sweet hay.

Once sanding this land will improve it for a vast number of years, and it will yield two crops of hay in the year, if there be weather to make it in. Some land in Cheshire has been, by this means, rendered of twelve times its former value to the owner. The bogs of Ireland when drained, have been rendered very fruitful land, by mixing sand in this manner among the earth, of which they consist. Add to this, that in all these boggy lands, the burning them, or firing their own turf upon them, is also a great advantage. The common peat, or turf-ashes, mixed with the sand for these purposes, add greatly to its virtue. Sea-sand, which is thrown up in creeks and other places, is by much the richest of all sand for manuring the earth; partly its saltness, and partly the fat and unctuous filth that is mixed among it, give it this great virtue. In the western parts of England, that lie upon the sea-coast, they make very great advantages of it. The fragments of sea-shells also, which are always in great abundance in this sand, add to its virtues; and it is always the more esteemed by the farmers, the more of these fragments there are among it.

The sea-sand, used as manure in different parts of the kingdom, is of three kinds: that about Plymouth, and on other of the southern coasts, is of a blue-grey colour like ashes, which is probably owing to the shells of muscles, and other fish of that or the like colour, being broken and mixed among it in great quantity. Westward, near the Land's end, the sea-sand is very white, and

about the isles of Scilly it is very glistering, with small particles of talc; on the coasts of the North Sea, the sand is yellowish, brown, or reddish, and contains so great a quantity of fragments of cockle-shells, that it seems to be chiefly composed of them. That sea-sand is accounted best, which is of a reddish colour: the next in value to this is the bluish, and the white is the worst of all. Sea-sand is best when taken up from under the water, or from sand-banks, which are covered by every tide. The small grained sand is most sudden in its operation, and is therefore best for the tenant who is only to take three or four crops; but the coarse or large grained sand is much better for the landlord, as the good it does lasts many years.

When the land has been well manured with the large sand, they take four crops of corn from it, and then lay it down for pasture for six or seven years before they plow it again. The grass is so good, that they commonly mow it for hay the first year; it always abounds very much with the white-flowered clover. If the grass grows but short, it is the farmer's interest to feed his cattle upon it, and it will turn to as good account this way, being very sweet and rich, and making the cattle fat, and the cows yield a very large quantity of milk.

SAND-BAGS, in the art of war, are bags filled with earth or sand, holding each about a cubic foot: their use is to raise parapets in haste, or to repair what is beaten down.

SAND-EEL, *Ammodytes*, in ichthyology. See AMMODYTES.

SAND-FLOOD, a terrible mischief, incident to the lands of Suffolk, and some others parts of England; which are frequently covered with vast quantities of sand, rolling in upon them like a deluge of water, from sandy hills in their neighbourhood.

The best way of stopping its progress is, by hedges of furze, planted one over another as they become level.

SAND-LANDS, or SANDY LANDS, in agriculture, are made up of sands of different colours and qualities; as white, blackish, reddish, or yellowish; and in the size of their particles, some being milder or harsher, and others very light, seeming mere dust. The grey, black, and ash-coloured sands are the worst of all, and are generally found on heaths and commons.

The most suitable plants for arable lands of this kind are white oats, rye, black wheat, and turneps: the natural produce in weeds, is quick-grass, sorrel, broom, furze, fern, and heath. The best manure for them is either marl or such clay as will break with the frosts. Cow-dung is also said to be good for such lands; and many use with success chalk, mud, and the half rotten straw of dunghills.

SANDAL, in antiquity, a rich kind of slipper, worn on the feet by the Greek and Roman ladies, made of gold, silk, or other precious stuff, consisting of a sole, with an hollow at one extreme to embrace the ankle, but leaving the upper part of the foot bare.

SANDARACH, in natural history, a very beautiful native fossil, though too often confounded with the common facitious red arsenic, and with the red matter formed by melting the common yellow orpiment.

It is a pure substance, of a very even and regular structure, is throughout of that colour which our dyers term an orange-scarlet, and is considerably transparent even in the thickest pieces. But though with respect to colour, it has the advantage of cinnabar while in the mass, it is vastly inferior to it when both are reduced to powders. It is moderately hard, and remarkably heavy, and when exposed to a moderate heat, melts and flows like oil: if set on fire, it burns very briskly.

It is found in Saxony and Bohemia, in the copper and silver mines, and is sold to the painters, who find it a very fine and valuable red: but its virtues or qualities in medicine, are no more ascertained at this time, than those of the yellow orpiment.

Gum-SANDARACH, is a dry and hard resin, usually met with in loose granules, of the bigness of a pea, a horse-bean, or larger; of a pale whitish yellow, transparent, and of a resinous smell, brittle, very inflammable, of an acrid and aromatic taste, and diffusing a very plea-

sant smell when burning. It is produced from a species of the juniper, and the *cedrus baccifera*. See JUNIPER.

It flows only from these trees in hot countries; but the natives promote its discharge by making incisions in the bark.

What is obtained from the cedar is more fragrant, especially when burnt; but it is seldom to be met with separate in the shops, both being mixed together under the common name of sandarach.

Sandarach is good in diarrhoeas, and in hæmorrhages; where its dose is from ten grains to half a dram: it is also sometimes prescribed in gonorrhæas, and the fluor albus; but at present it is much disused in medicine. It is, however, much used by our writing-masters, who make a powder of it which they call pounce.

The varnish-makers make a kind of varnish of it by dissolving it in oil of turpentine, or linseed, or in spirit of wine.

SANDIVER, a whitish salt, continually cast from the metal, as it is called, whereof glass is made; and swimming on its surface, is skimmed off.

Sandiver is also plentifully thrown out in the eruptions of vulcanos; some is of a fine white, and others tinged blueish, or yellowish.

Sandiver is detergent, and good for foulnesses of the skin. It is also used by gilders of iron.

SANDIX, a kind of minium, or red-lead, made of ceruse; but much inferior to the true minium. See the articles MINIMUM and CERUSE.

SANGUIFICATION, in the animal œconomy, the conversion of chyle into true blood.

Blood is formed from chyle by various and successive degrees. A few hours after meals, the chyle is found conveyed into the blood, though not assimilated. Hence, when after a liberal meal blood is taken from the vein, besides the serum and the red part, there is a white, sweet, and chylous part found fluctuating in the blood. In a few hours the chyle, conveyed with the blood thro' the vessels, is separated from the blood by the fabric of the breasts, and affords milk, which is of a different nature both from blood and chyle; for in milk there begins to be formed that tendency to concretion which is already present in the serum of the blood, for it yields cheese. But this tendency to concretion is never found in the chyle. Hence we may artificially imitate the preparation of chyle in emulsions, but never the nature of milk.

When a sound woman for twelve hours totally abstains from meat and drink, her milk begins to be saline and yellowish. If she abstains still longer, nothing is found in the blood taken from her veins, but what (like the white of an egg) is, by means of the fire, concreted, which never happens in the chyle.

Hence we may conclude, that the bodies of sound persons are the formers and producers of their own blood, in the same manner as any plant, by its peculiar fabric, prepares its sap from the juices of the fertile earth and the genial influences of the circumambient air.

But in the human body the formation of blood depends principally upon the efficacy of the circulation, by which the vessels act upon their contained fluids. Hence in the most robust persons the blood is reddest, or rather almost black, in consequence of its saturated red colour, and is concreted almost the very moment it is left in a state of rest. And in acute diseases, when the circulation is encreased, all the parts are intensely red, and the serum of the blood is converted into a scissile mass. But in weak persons in whom the efficacy of the circulation is far less, all the parts are pale and languid, whilst the blood is thin and hardly capable of concretion. But when in such persons, with due exercise and proper remedies, the circulation is augmented, the red colour and due cohesion of the blood return.

SANGUINARIA, BLOOD-WORT, a genus of plants, the flower of which consists of eight very patent petals; and the fruit is an oblong ventricose capsule, containing a great many roundish and acuminate seeds.

SANGUINE, in general, something abounding with, or resembling blood.

Among

Among heralds, the term sanguine is often given to the colour more usually called murrey; being made of red lake tinged with a little Spanish brown; it is chiefly used in the coats of the knights of the Bath, and is represented, in engraving, by hatches like those of purple. See PURPURE.

SANGUIS, BLOOD, in the animal œconomy. See BLOOD.

SANGUISORBA, BURNET, in botany. See the article BURNET.

SANHEDRIM, or SANHEDRIN, among the Jews, the great council of the nation, consisting of seventy senators, taken partly from among the priests and Levites, and partly out of the inferior judges, who formed what is called the lesser sanhedrim. The room they met in, was a rotunda, half of which was built without the temple, and half within. The nasi, or president of the sanhedrim, sat upon a throne, with his deputy on his right hand, his sub-deputy on his left, and the other senators ranged in order on each side.

The authority of this council was very extensive, for they decided such causes as were brought before them by way of appeal from the inferior courts; and the king, the high priests, and prophets, were under the jurisdiction of this tribunal. They had the right of judging in capital cases, and sentence of death might not be pronounced in any other place; for which reason the Jews were forced to quit this hall, when the power of life and death was taken out of their hands, forty years before the destruction of the temple, and three years before the death of Christ.

There were several inferior sanhedrims in Palestine, each of which consisted of twenty-three persons; all these depended on the great sanhedrim of Jerusalem.

SANIES, in medicine, a ferous putrid matter, issuing from wounds; it differs from pus, which is thicker and whiter.

SANTALUM, SAUNDERS, in the materia medica, a hard, odoriferous medicinal wood, brought from the East-Indies, of which there are three sorts, viz. the yellow, white, and red; the yellow or citrine saunders, is a beautiful wood; of the colour of lemon-peel; of a smell somewhat like a mixture of musk and roses, and of a somewhat acrid and aromatic taste, with a slight bitterness. The white saunders resembles the yellow, and is of the same fragrant smell and aromatic taste, but in a more remiss degree. Both these sorts should be chosen sound, firm, heavy, and of a good smell when cut; they should also be chosen in the block, and not cut into chips as they usually are, for in this manner they soon lose much of their virtue. The red saunders is of a dense and compact texture, remarkably heavy and very hard. It is brought to us in logs of considerable length, the out part of which is of a dusky, and the inner of a blood red; it has but little smell, and is of an austere taste.

All these sorts are attenuants, and all have an astringency, but the red most of all. They are accounted cordials, and are said to be good in obstructions of the viscera; but they are little used, except as ingredients in some of the compositions of the shops.

SANTOLINA, FEMALE SOUTHERN-WOOD, or LAVENDER-COTTON, a plant, the compound flower of which is uniform, consisting of a number of infundibuliform hermaphrodite corollulæ, quinquefid at the limb; which are each followed by a single seed, contained in the cup.

The medicinal virtues ascribed to santolina, are, in general, the same with those of the abrotanum mas, or male southern-wood: it is however particularly recommended in uterine complaints; and its seed is good for destroying worms. See the article SOUTHERN-WOOD.

SAP, in physiology, a juice furnished by the earth, and changed into the plant, consisting of fossil parts, other parts derived from the air and rain, and others from putrified animals, plants, &c. See the article JUICE.

This juice enters the plant in form of a fine and subtile water, which the nearer it is to the root, the more it retains of its proper nature; and the farther from the root, and the more action it has sustained, the nearer it

approaches to the nature of the vegetable: consequently, when the juice enters the root, it is earthy, watery, poor, acid, and scarcely oleaginous at all. In the trunk and branches it is farther prepared, though it still continues acid, as we find by tapping a tree in the month of February. The sap being here carried to the germs or buds, is more concocted; and here having unfolded the leaves, these come to serve as lungs for the circulation and farther preparation of the juice. By such means is the sap still farther altered and digested, as it is farther in the petals or leaves of the flowers, which transmit the juice, now brought to a farther subtilty, to the stamina; these communicate it to the farina, or dust, in the apices, which is, as it were, the male seed of the plant; where having undergone a farther maturation, it is shed into the pistil, which performs the office of an uterus or womb; and thus having acquired its last perfection, it gives rise to a new fruit or plant. The sap having thus gone its stage, from the root to the remote branches, and even the flower; and having, in every part of its progress deposited something both for aliment and defence, what is redundant passes out into the bark, the vessels of which are inoculated with those in which the sap mounts; and through which it descends to the root, and thence to the earth again. And thus a circulation is effected.

SAP, or SAPP, in the art of war, is the digging deep under the earth of the glacis, in order to open a covered passage into the moat. It is only a deep trench, covered at top with boards, hurdles, earth, sand-bags, &c. and is usually begun five or six fathoms from the salient angle of the glacis.

SAPATA, or ZOPATA. See the article ZOPATA.

SAPINDUS, the SOAPBERRY-TREE, in botany, a plant the flower of which consists of four oval petals; and the fruit of three capsules, each including a globose nut.

The berries of this tree are used for washing, instead of soap, whence the English name.

SAPO, SOAP. See the article SOAP.

SAPONARIA, SOAPWORT, in botany, a plant the flower of which consists of five petals, with a plane limb; and its fruit an unilocular capsule, containing a number of small seeds.

The root of this plant is accounted aperient, corroborant, and sudorific; and even preferred by some to scissaras in these intentions. The leaves, agitated with water, raise a saponaceous froth, which has nearly the same effects with solutions of soap itself, in taking out spots from cloths, whence the name.

SAPPHIRE, a pellucid gem, which, in its finest state, is extremely beautiful and valuable, and second only to the diamond in lustre, hardness, and price. Its proper colour is a pure blue; in the finest specimens it is of the deepest azure, and in others varies into paleness in shades of all degrees between that and a pure crystal brightness and water, without the least tinge of colour, but with a lustre much superior to the crystal. They are distinguished into four sorts, viz. the blue sapphire, the white sapphire, the water sapphire, and the milk sapphire.

The gem known to us by this name is extremely different from the sapphire of the ancients, which was only a semi-opaque stone, of a deep blue veined with white, and spotted with small gold-coloured spangles, in the form of stars, and was only a more beautiful kind of the lapis lazuli: but our sapphire they have described under the name of beryllus aeroides, or the sky-blue beryl.

The finest sapphires in the world are brought from the kingdom of Pegu, in the East-Indies, where some are found perfectly colourless, and others of all the shades of blue; these are all found in the pebble-form. We have very fine sapphires also, partly pebble, partly crystal-shaped, from Bishnagar, Conanor, Calicut, and the island of Ceylon: these also are of all the shades of blue. And in Ceylon there are sometimes found a sort of bastard gems, of a mixed nature between the sapphire and ruby. The occidental are from Silesia, Bohemia, and many other parts of Europe; but though these are often

very

very beautiful stones, they are greatly inferior, both in lustre and hardness, to the oriental.

The sapphire is said to have very great virtues as a cordial, sudorific, and alexipharmic; but we have no good testimony of any body's having ever found this by experiment.

SAPPHIRINE WATER, in the materia medica, also called blue eye water, is thus prepared: pour a pint of lime-water, made strong and fresh, into a copper-vessel; add to it a dram of crude sal armoniac, and throw in some filings or small pieces of copper, and let it stand till it has acquired a beautiful colour.

This is used as an eye-water; as also to deterge old ulcers: and sometimes it is mixed with other things in injections in gonorrhœas.

SARABAITES, a sort of monks among the ancient christians, who did not resort to the wilderness as others did, but lived publicly in cities. Two or three of them usually dwelt together, but they had no rule or government: they however observed very strict fasts; wore loose sleeves, wide stockings, coarse cloaths, frequently fighed, and always bitterly inveighed against the clergy.

SARABAND, a musical composition in triple time, the motions of which are slow and serious.

Saraband is also a dance to the same measure, which usually terminates when the hand that beats rises; by which it is distinguished from a courant, which ends when the hand that beats the time falls; and is otherwise much the same as the minuet.

The saraband is said to be originally derived from the Saracens, and is usually danced to the sound of the guitar or castanettes.

SARCASM, in rhetoric, a keen bitter expression which has the true point of satyr, by which the orator scoffs and insults his enemy: such was that of the Jews to our Saviour, "He saved others, himself he cannot save."

SARCOCELE, in surgery, a spurious rupture, or hernia, wherein the testicle is considerably tumified or indurated, like a schirrhus, or much enlarged by a fleshy excrescence, which is frequently attended with acute pains, and sometimes ulceration, so as to degenerate at last into a cancerous disposition. See **HERNIA**.

When the tumour of the testicle is accompanied with hardness, the causes are much the same with those of a schirrhus. When there is a fleshy excrescence, then the cause is usually some contusion or other external violence. The tumour differs, as to its magnitude, being frequently no larger than an hen's egg, though sometimes as big as a man's fist.

The signs whereby the sarcocoele may be distinguished from other ruptures are principally the hardness of the tumour, and its seat being in the testicle; whereas the true herniæ are distinct from the testicle, and softer to the touch. If a sarcocoele be not timely brought to a suppuration, it very easily degenerates into a cancer; and if both testicles are affected, castration is often necessary; but if the tumour proceeds through the inguen, up to the abdomen, even castration will be useless, and death is the consequence.

A recent sarcocoele, according to Heister, may frequently be suppured by digestive medicines, as well internal as external. When these medicines prove ineffectual, the size and pain of the tumour increase, and it seems inclined towards a cancerous disposition, if it has not reached the ring of the abdominal muscles, there is then but one way left of relieving the patient, and that is by a dexterous and timely extirpation of the disordered testicle, or both, if they are affected, which is termed castration, and renders the patient impotent.

In this operation the spermatic vessels are first to be tied securely with a ligature near the inguen, and afterwards divided, to give the patient less pain; and as a division of these vessels, which are so much enlarged, may be attended with a fatal hæmorrhage, it may be prudent, for the greater security, to pass a double ligature round those vessels, one below the other; or else not to extirpate the testicle so soon as it is freed from the scrotum, and its vessels strictly tied, but to wait a few days, till the testicle begins to grow flaccid and mortifies,

which is a sign the spermatic vessels are well secured, and may be divided without any danger; but if that does not follow, the ligature is not strict enough, and another must be made, much tighter.

If a patient should be troubled with a fleshy excrescence upon his testicle, which is in other respects sound, and finds no relief from medicines, the testicle may be preserved, and yet the patient freed from his disorder, by opening the scrotum, and extirpating the offending part only.

With regard to the dressing, it is to be done with scraped lint and compresses, and secured by a proper bandage; and to abate the inflammation, which sometimes arises, a discutient cataplasm may be used, and the wound afterwards treated with some digestive ointment or vulnerary balsam. See **WOUND**.

SARCOCOLLA, in pharmacy, a gum-resin, which approaches greatly to the nature of the simple gums.

It is brought to us from Persia and Arabia, in small granules, moderately heavy, and of a whitish, brownish, or reddish colour, very friable, of a faintish disagreeable smell, and of an acrid and nauseous taste.

Hoffman absolutely condemns the internal use of it. However, it is recommended in ophthalmias, and discharges of a sharp matter upon the eyes; and is generally ordered to be dissolved in milk for this purpose.

SARCOLOGY is that part of anatomy which treats of the soft parts, viz. the muscles, intestines, arteries, veins, nerves, and fat. See the articles **MUSCLE**, **INTESTINES**, &c.

SARCOMA, in surgery, denotes any fleshy excrescence. See **EXCRESCENCE**.

Sarcomata of the nose, eyes, &c. may be sometimes removed by caustics; but the extirpating them with the knife or scissars is the safest and most eligible method. The wound should be suffered to bleed a while, after which it may be washed with a collyrium made of aloes, tutty, and sugar of lead, mixed in rose-water.

SARCOPHAGOUS MEDICINES, in surgery, &c. are those which eat away proud flesh, and otherwise called caustics.

SARCOTICS, in surgery, medicines which generate flesh in wounds.

SARCULATION, in the antient agriculture, a kind of hoeing, used to root up the weeds in their peas, &c.

SARDA, the **PILCHARD**, in ichthyology. See **PILCHARD**.

SARDA, the **CARNELIAN**, in natural history. See **CARNELIAN**.

SARDACHATES, a beautiful species of agat, of a cloudy and spotted flesh-colour. See **AGAT**.

SARDONYX, in natural history, a genus of semipellucid gems, of the onyx structure, zoned or tabulated, and composed of the matter of the onyx variegated with that of the red or yellow carnelian. See **CARNELIAN** and **ONYX**.

Of this stone there are several beautiful species; as, 1. The thin zoned red sardonyx, or whitish onyx with thin snow-white and red zones. 2. The broad zoned red sardonyx; or horny onyx, with punctuated zones. 3. The horny onyx, with whitish and yellow zones; and is properly the yellow sardonyx, and the chrysolite onyx of the antients. 4. The orange-coloured sardonyx; or bluish white onyx, with orange-coloured and whitish zones.

SARPLAR of Wool, the same with a pocket or half a sack.

SARRASIN, or **SARRAZIN**, in fortification, the same with herse. See **HERSE**.

SARRITION, in the antient husbandry, the same with what we call hoeing.

SARSAPARILLA, the root of a species of bindweed, growing in the Spanish West-Indies, and scarcely bearing the winters of our climate without shelter. The root consists of a number of strings, of great length, about the thickness of a goose-quill or thicker, flexible, free from knots, composed of fibres running their whole length, so that they may be stript in pieces from one end to the other. They are covered with a thin, brownish, or yellowish-ash-coloured skin, under which lies a thicker

thicker white friable substance, and in the middle runs a woody pith.

This root has a farinaceous somewhat bitterish taste, and no smell. To water it communicates a reddish brown, to rectified spirit a yellowish red tincture, but gives no considerable taste to either menstruum. An extract, obtained by inspissating the spirituous tincture, has a weak, somewhat nauseous, balsamic bitterishness, which is followed by a slight but durable pungency: the watery extract is much weaker, and in larger quantity.

Sarsaparilla was first brought into Europe by the Spaniards, about the year 1563, with the character of a specific for the cure of the lues venerea, which made its appearance a little before that time. Whatever good effects it might have produced in the warmer climates, it was found to be insufficient in this, inasmuch that many have denied it to have any virtue at all, and supposed that it could do no more, than by its farinaceous softness to obtund the force of the gastric fluid, and thus weaken the appetite and digestion. It appears however, from experience, that though greatly unequal to the character which it bore at first, yet, in many cases, strong decoctions of it, drank plentifully and duly continued, are of very considerable service, for promoting perspiration, and what is called sweetening or purifying the blood and humours. In the Medical Observations published by a society of physicians in London, there are several instances of its efficacy in venereal maladies, as an assistant to mercury, or when mercury had preceded its use: it oftentimes answered, and that speedily, after mercurial unctions, and long continued courses of strong decoctions of guaiacum, had failed. Dr. Harris says that infants who have received the infection from the nurse, though full of pustules and ulcers, and sometimes troubled with nocturnal pains, are cured by sarsaparilla without mercurials: he directs the powder of the root to be mixed with the food.

SARTORIUS, in anatomy, is both an abductor and elevator, serving to move the legs upwards and forwards, determining them to cross each other, as tailors sit with them, whence the name; it rises from the internal part of the anterior and superior spine of the ileum; and descending obliquely, is inserted into the upper and inner part of the tibia.

SASSAFRAS, in pharmacy, the wood of an American tree, of the laurel-kind, imported in large straight blocks: it is warm, aperient, and corroborant; and frequently employed, with good success, for purifying and sweetening the blood and juices; for which purpose an infusion, in the way of tea, is a very pleasant drink: its oil is very fragrant, and possesses most of the virtues of the wood.

It is an excellent diuretic and diaphoretic, and therefore good in obstructions of the viscera, cachexies, scorbutic complaints, and in the venereal disease.

SATELLITE, in astronomy, the same with a secondary planet, or moon; so called from its continually waiting upon or revolving round one of the primary planets. See PLANET.

Thus the moon may be called the satellite of the earth: but the term is chiefly applied to the new-discovered planets, which make their revolution about Saturn and Jupiter.

SATIR, SATIRE, or SATYR. See the article SATYR.

SATISFACTION, in law, is the giving a recompence for some injury done; or the payment of money due on bond, judgment, &c.

SATRAPA, or SATRAPES, in Persian antiquity, denotes an admiral; but more commonly the governor of a province.

SATTIN, a glossy kind of silk-stuff, the warp of which is very fine, and stands out so as to cover the coarser woof.

Some sattins are quite plain, others wrought; some flowered with gold or silver, and others striped, &c.

The Chinese sattins are most valued, because of their cleaning and bleaching easily, without losing any thing of their lustre: in other respects they are inferior to those of Europe.

SATTINET, a slight thin kind of sattin, commonly striped, and chiefly used by the ladies for summer night-gowns.

SATURATION, in chemistry, is the impregnating an acid with an alkali, or *vice versa*, till either will receive no more, and the mixture become neutral.

SATURDAY, the seventh or last day of the week, so called from the idol Seater, worshipped on this day by the ancient Saxons, and thought to be the same as the Saturn of the Latins. Saturday answers to the Jewish Sabbath. See SABBATH.

SATUREIA, SAVORY, in botany, a genus of plants, with a monopetalous ringent flower, and no pericarpium; the seeds, which are four and roundish, being contained in the bottom of the cup.

The leaves of summer-savory are very pungent, warm, and aromatic; and afford, in distillation with water, a subtile essential oil. Both are esteemed good in crudities of the stomach, asthmas, and menstrual obstructions.

SATURN, ♄, in astronomy, the remotest of the superior planets, which, by reason of its great distance from the sun, shines but with a feeble light. See PLANET.

Though Galileo's telescope was sufficient to discover all Jupiter's moons, it could not reach Saturn's, on account of their great distance; but yet this sagacious observer found Saturn, by reason of his ring, had a very odd appearance; for his glass was not good enough to exhibit the true shape of the ring, but only a confused idea of that and Saturn together, which in the year 1610, he advertised in the letters of this sentence transposed: "Altissimum planetam tergeminum observavi;" i. e. I have observed Saturn to have three bodies.

This odd phenomenon perplexed the astronomers very much, and various hypotheses were formed to solve it; all which appeared trifling to the happy Huygenius, who applied himself purposely to improve the grinding of glasses, and perfecting long telescopes, to arrive at a more accurate notion of this planet and its appendage. Accordingly, in 1655, he constructed a telescope of twelve feet; and viewing Saturn divers times, he discovered something like a ring encompassing his body; which afterwards, with a tube of twenty-three feet, he observed more distinctly, and also discovered a satellite revolving about the planet. This Huygenian satellite is the fourth in order from Saturn. See plate CI. fig. 3.

In the year 1659, Huygens published his discovery in relation to Saturn's ring, in the letters of this sentence transposed: "Annulo cingitur tenui plano, nusquam coherente, ad eclipticam inclinato;" i. e. Saturn is encompassed by a thin plane ring, no where cohering to his body, and inclined to the plane of the ecliptic. This inclination of the ring to the ecliptic is determined to be about 31 degrees by Huygens, Romer, Pickard, Campanus, &c. though by a method not very definitive. However, since the plane of the ring is inclined to the plane of the earth's motion, it is evident, when Saturn is so situated that the plane of his ring passeth through the earth, we can then see nothing of it; nor can we see it when the plane passes between the sun and the earth, the dark side being then turned to us, and only a dark list appearing upon the planet, which is probably the shadow of the ring. In other situations the ring will appear elliptical, more or less; when it is most so, the heavens appear through the ecliptic space on each side Saturn (which are called the ansæ), and a fixed star was once observed by Dr. Clarke's father in one of them.

The nodes of the ring are in 19° 45' of Virgo and Pisces. During Saturn's heliocentric motion from 19° 45' to the opposite node, the sun enlightens the northern plane of the ring.

Since Saturn describes about one degree in a month, the ring will be visible through a good telescope till within about fifteen or twenty days before and after the planet is in 19° 45' of Virgo or Pisces. The time therefore may be found by an ephemeris, in which Saturn, seen from the earth, shall be in those points of the ecliptic; and likewise when he will be seen from the earth in 19° 45' of Gemini and Sagittarius, when the ring will be most open, and in the best position to be viewed.

There have been some grounds to conjecture that Saturn's ring turns round an axis; but that is not yet demonstrable. This wonderful ring, in some situations, does also appear double; for Cassini, in 1675, observed it to be dissected quite round by a dark elliptical line, dividing it, as it were, in two rings, of which the inner one appeared brighter than the other. This was oftentimes observed afterwards, with tubes of thirty-four and twenty feet, and more evidently in the twilight or moonlight, than in a darker sky. This ring is the most remarkable thing in the whole planetary system, there being nothing of that nature hitherto discovered in any of the other planets. Kepler, in his *Epitom. Astron. Copernic.* and after him Dr. Halley, in his enquiry into the causes of variation of the needle, *Philos. Transact.* n° 195, suppose our earth may be composed of several crusts or shells, one within another, and concentric to each other. And if so, then it is possible the ring of Saturn may be the fragment or remaining ruins of his formerly exterior shell, the rest of which is broken or fallen down upon the body of the planet. And if Saturn ever had such a shell round it, its diameter would then have appeared as big to an eye at the sun, as that of Jupiter doth now, when seen from thence.

Since the outward margin of the ring is distant from Saturn 2° of Saturn's semi-diameter, this cannot be seen at the distance of 64 degrees from Saturn's equator, in whose plane the ring is placed. Therefore, a spectator, placed in a latitude higher than that, can never see the ring at all; so that there is a zone of almost 53 degrees broad towards either pole, to whom this famous ring can never appear. And as the spectator shall move nearer the pole, first one, then the second satellite, next the third and fourth, and, when he is come within one degree of the pole, even the fifth satellite cannot be seen, unless by refraction; and, in the winter-time, neither sun, moon, nor any planet will be there visible, unless perhaps a comet.

If the eye be supposed to be placed in the equator of Saturn, or in the zone nearly adjoining, it can never see those stars that are in or very near the equator, nor any one of the satellites; because the ring will always hide them; and then at the equinoxes it cannot see the sun; and if it were any where else placed, it could not then see the ring; because neither of its faces will then appear illuminated by the sun. The breadth of this ring it is hard to determine from our earth, because its thickness is so small; but Mr. Huygens makes it to be about 600 German miles.

For one half of Saturn's year (viz. fifteen of ours) only one face of the ring will be enlightened by the sun; whence the inhabitants, which may be supposed to live in that hemisphere, to which this face of the ring is turned, or to whom it is summer, will see that part of the ring which is above their horizon, shining faintly by day, as our moon doth when the sun is above our horizon, but brighter and stronger by night, as our moon doth in the sun's absence; and, after sun-set, the eastern part of this enlightened arch will fall within the shadow of Saturn; which shade will ascend, as night comes on, and at night will be at the highest; and then will descend again towards the western part of the ring, according as the sun comes more and more to the eastward.

This enlightened arch will always shew how to describe a meridian line; for a plane perpendicular to the horizon, and passing through the vertex of the arch, will be in the true meridian.

To an eye placed any where without, and at less than fifty degrees distant from the equator, this enlightened arch of the ring will appear concave as well as convex, like a kind of furnace or vault, rising above the horizon; but to an eye more than 52 minutes, and less than 64 degrees, distant from the equator, the hollow or concave part will not be visible; but there will appear a brightish body arising, as it were, out of the ground, and contiguous to the horizon.

For the other half of Saturn's year, while the sun declines towards the depressed pole, or during the fifteen years winter, the ring will not be visible, as having not that face illuminated which is turned to the spectator's eye; but, however, will render itself sensible, by cover-

ing from the sight such stars and parts of the heavens as are opposite to it, or apparently behind it. The shade of the ring also will be extended more and more towards the nearer pole; so that to an eye placed any where within the aforesaid space, the sun, when he attains such a certain declination, will appear to be covered or eclipsed just at noon, and then straight to emerge out of the shadow. The next day, the like phenomenon will happen, but the eclipse will begin sooner, and will be over later: and these meridian eclipses will daily increase in their duration until the middle of winter; and then they will decrease again gradually, till at last they will come to nothing again, viz. when the sun, returning from the tropic, hath the same declination as he had when these meridional eclipses began.

And this will happen, if an eye be placed in any latitude greater than 25 or 26 degrees; but if in a latitude less than this, when the meridional darkness is of the greatest duration, the sun will suddenly appear just in the meridian, and then straightway will be eclipsed again. The next day there will appear the like sort of light, but it will last longer; and this meridian light will grow still longer and longer in duration, till mid-winter, and then, like the darkness above mentioned, it will be continually decreasing, until it quite disappear.

And from hence it is plain, that there is the greatest difference between summer and winter in the globe of Saturn, of all the other planets; and this both on the account of the long duration of each, and the great declination of the sun from the equator; and also by reason of these meridional darknesses of the winter, arising from the ring's eclipsing the sun.

If an eye were placed in Saturn, the diameter of the sun would appear almost ten times less than it doth to us; and consequently his disc, light, and heat, will be there ninety times less. Saturn's year is almost thirty of ours; but the length of his day is yet uncertain, because the time of his revolution round his axis is not yet known; but Mr. Huygens judges they are longer than the days of Jupiter. That great astronomer supposeth the axis of Saturn to be perpendicular to the plane of his ring, and of the orbits of the satellites; if so, then there will be the same position of the equator and poles, as to the fixed stars, as there is in our earth; the same pole-star and the fixed stars will appear to rise and set after the same manner, in the same latitudes. There is a vast inequality in the length of the day, in several parts of this planet; and as great a diversity of summer and winter; which depends on the quantity of the inclination of the plane of the equator to the plane of the orbit of Saturn round the sun, which Huygens makes to be 51 degrees, which is almost one third more than our earth, where yet the differences and variety of seasons and weather are very sensible. For in Saturn, in the latitude of 50 degrees, the longest day will have no night at all, and the longest night will have no day. And the two frigid zones will be each of them 62 degrees broad, at least ten times as large as the whole surface of our earth. The eye thus placed will be able to discern none of the planets but Jupiter, which will appear always to accompany the sun, and never to be from him above 37 degrees. The parallax of the sun in Saturn is but nine seconds, and therefore insensible; but the parallaxes of all his moons or satellites are very considerable, and therefore their distances from him will be easily computable.

Satellites of SATURN, are five moons; the first or inmost of which revolves about Saturn in one day, 21 hours, and eighteen minutes, at the distance of near two semi-diameters of the ring; the second in two days, 17 hours, and 41 minutes, at the distance of $2\frac{2}{3}$ semi-diameters; the third, in four days, 12 hours, and 25 minutes, at the distance of $3\frac{2}{3}$ semi-diameters; the fourth in 15 days, 22 hours, and 41 minutes, at the distance of eight semi-diameters; and the fifth, in 70 days, 22 hours, and four minutes, at the distance of $23\frac{1}{3}$ semi-diameters of Saturn's ring.

In the beginning of the year 1665, the celebrated Mr. Huygens, as already observed, discovered the biggest of Saturn's satellites; the other four satellites of Saturn were all the discovery of Mr. Cassini, the third and fifth in the years 1671, 1672, and 1673; but the first and second were

were not discovered till the year 1684, by extraordinary telescopes of eighty, one hundred, one hundred and fifty, and two hundred feet in length.

SATURN, in chemistry, &c. an appellation given to lead. See LEAD.

SATURN, in heraldry, denotes the black colour, in blazoning the arms of sovereign princes.

SATURNALIA, in Roman antiquity, a festival observed about the middle of December, in honour of the god Saturn, whom Lucan introduces, giving an account of the ceremonies observed on this occasion thus: "During my whole reign, which lasts but for one week, no public business is done; there is nothing but drinking, singing, playing, creating imaginary kings, placing servants with their masters at table, &c. There shall be no disputes, reproaches, &c. but the rich and poor, masters and slaves, shall be equal, &c."

On this festival the Romans sacrificed bare-headed, contrary to their custom at other sacrifices.

SATURNINE, an appellation given to persons of a melancholy disposition, as being supposed under the influence of the planet Saturn.

SATYR, in the heathen mythology, a fabulous kind of demi-god, or rural deity, of the antient Romans, represented with goats feet, and sharp pricked-up ears. Some think the notion of these satyrs might have been derived from the monkeys known at present under the same name.

SATYR or SATIRE, in matters of literature, a discourse or poem exposing the vices and follies of mankind.

The satyr of the Greeks differed from that of the Romans, as being a kind of interlude annexed to tragedy, with a view to remove from the audience too melancholy impressions. But satyr, as we now have it, is entirely Roman, if we may believe Quintilian, who says, "*Satira quidem tota, nostra est*;" or Horace, who styles Ennius the inventor of a poem unknown to the Grecians, meaning satyr, according to the opinion of all his interpreters. Scaliger however expressly denies it to be of Roman original; and there is reason, indeed, as we shall see hereafter, to understand these expressions of Quintilian and Horace with some abatement. Those that will not allow it to be derived from the Grecians, but entirely Roman, maintain that satyr should be writ with an *i*, not a *y*; and that it is not derived from *satyrus*, but *satur*: *satira* therefore is the same as *satura*, as *maximus* antiently *maxumus*.

When the Romans grew more polite, these kind of verses refined in proportion, but they retained still their jibes and banters, and kept so far to their first institution, as to make the follies of human life the object of their ridicule. From hence proceeded satyr, so called from the farrago and variety of matter it contained. It was improved likewise with music and dancing, which, considering its being carried on in dialogue, made it resemble somewhat of the dramatic kind; nor had the Romans any thing that came so near the drama as this did. Afterwards, when they had received both tragedy and comedy from the Grecians, they were so taken with the novelty, that satyr for some time lay neglected: but coming again into esteem, it was added as a kind of exodium to comedy. Thus things went on for some years till Ennius arose, endued with wit and true poetic fire, who observing how fond the people were of seeing the vices of mankind exposed upon the stage, thought a poem on the said subject, without the decoration of scenes and action, might have the same effect. Accordingly he attempted satyrs in the same form we now see them, only he did not confine himself to the hexameter, but made use of all sorts of measure. The remains we have of this poet are noble indications of the strength of his genius; and Horace and Virgil have shewn what opinion they had of his writings by borrowing so much from them. After Ennius succeeded Pacuvius; but his works are all lost, excepting some fragments, and those of uncertain authority. Next came Lucilius, of whom also we have some fragments remaining: but his excellencies and imperfections are very amply set forth by Horace, whose words we have no occasion to cite here.

It must be allowed however, that one species of satyr owes its perfection to Horace, as another does to Juvenal.

A third kind was the Varronian or Menippean satyr, so called from Menippus, a cynic philosopher among the Grecians, whose doctrine Varro followed. It was a sort of medley, consisting of not only all kinds of verse, but of verse and prose mixed together; a specimen of which we have in Petronius's Satyricon. We have none of Varro's poetical works remaining, except some small fragments; which is the more to be lamented, considering the character Quintilian gives of him, that he was the most learned of all the Romans.

The word satyr was antiently taken in a less restrained sense than it is at present, not only as denoting a severe poem against vice, but as consisting of precepts of virtue, and the praises of it: and even in the satyrs, as they are called, of Horace, Juvenal, and Persius, &c. which are principally levelled against the weakness, the follies, or vices of mankind, we find many directions, as well as incitements, to virtue. Such strokes of morality Horace is full of; and in Juvenal they occur very frequently. All of them, sometimes, correct vice like moralists; we may say, like divines rather than satyrists.

With respect to the nature and different species of it, satyr, in general, being a poem designed to reprove the follies and vices of mankind, is twofold; either the jocose, as that of Horace; or the serious, like that of Juvenal: the former hidden, the latter open: that generally makes sport with vice, and exposes it to ridicule; this probes it to the bottom, and puts it to the torture: and so far is it from not deserving the title of satyr, as some pretend, that it seems rather a more noble species of it; and the genteel strokes of Horace, how ingenious soever, are less affecting than the poetic rage and commendable zeal of Juvenal.

They both agree in being pungent and cutting, yet are distinguished by very evident marks. The one is pleasant and facetious, the other angry and austere; the one smiles, the other storms: the foibles of mankind are the object of one; greater crimes of the other: the former is always in the pleasing style; the latter generally in the sublime: that abounds with wit only; this adds to the salt bitterness and acrimony. Either kind of satyr may be writ in the dialogue or epistolary manner; and we have instances of both forms in Horace, Juvenal, and Persius. As some of Horace's, which are called satyrs, are as truly epistles; so many of his epistles might as well be called satyrs: for example, *Qui fit Mecænas*, &c. might, with equal reason, be reckoned among the epistles; and *Prima dicta, mihi*, &c. among the discourses or satyrs; if the author or editor had so thought fit.

The chief satyrists among the antients are Horace, Juvenal, and Persius; those among the moderns, Regnier and Boileau in French; and Dryden, Oldham, Rochester, Buckingham, Pope, Young, &c. among the English.

SATYRIUM, GOAT'S-STONES, a genus of plants, the flower of which consists of five ovato-oblong petals; and its fruit is an oblong, unilocular capsule, containing a great many scabiform and very small seeds.

The root of this plant is composed of two oval bulbs, of a whitish colour, a sweetish taste, and a faint unpleasant smell; it abounds with a glutinous slimy juice; and, like other mucilaginous vegetables, it serves to thicken the thin serous humours, and defend the solids from their acrimony: it has also been celebrated, though on no very good foundation, for analeptic and aphrodisiac virtues; in which intentions it has also been frequently used.

SAUCISSE, or SAUSAGE, in the military art, a long train of powder, sewed up in a roll of pitched cloth, about two inches in diameter, serving to set fire to mines. See MINE.

There are usually two saucisses extended from the chamber of the mine to the place where the engineer stands; that in case one should fail, the other may take effect.

SAUCISSON, in fortification, a mass of large branches of trees bound together; and differing only from a fascine, as this is composed of small branches of twigs.

SAVIN, *Sabina*, in botany, a species of juniper, and famous as an hysseric and attenuant; and, indeed, it promotes

motes the discharges by urine, and the menses, more forcibly than safely, if not under very careful management.

SAVIOUR, an appellation peculiarly given to Jesus Christ, as being the true Messiah, and Saviour of the World.

Order of St SAVIOUR, a religious order in the Romish church, founded by St. Bridget, about the year 1345; and so called from its being pretended that our Saviour himself dictated to the foundress its constitutions and rules.

According to the constitutions, this order is principally founded for religious women who pay a particular honour to the holy virgin: but there are some monks of the order, to administer the sacraments and spiritual assistance to the nuns. The number of nuns is fixed at sixty in each monastery; and that of the religious priests at thirteen, according to the number of the apostles, of whom St. Paul was the thirteenth. There are also four deacons, representing the four doctors of the church, St. Ambrose, St. Augustine, St. Gregory, and St. Jerome; and eight lay-brothers; who all together make up the number of the thirteen apostles, and the seventy-two disciples of Jesus Christ. The nuns are not admitted till eighteen years of age, nor the friars before twenty-five; and they are to perform a year's novitiate.

SAUNDERS, the same with *santalum*. See the article *SANTALUM*.

SAW, an instrument which serves to cut into pieces several solid matters; as wood, stone, ivory, &c.

The best saws are of tempered steel ground bright and smooth; those of iron are only hammer-hardened: hence, the first, besides their being stiffer, are likewise found smoother than the last. They are known to be well hammered by the stiff bending of the blade; and to be well and evenly ground, by their bending equally in a bow.

The edge, in which are the teeth, is always thicker than the back, because the back is to follow the edge. The teeth are cut and sharpened with a triangular file, the blade of the saw being first fixed in a whetting-block. After they have been filed the teeth are set, that is, turned out of the right line, that they may make the kerf or fissure the wider, that the back may follow the better. The teeth are always set ranker for coarse cheap stuff than for hard and fine, because the ranker the teeth are set the more stuff is lost in the kerf. The saws by which marble, and other stones are cut, have no teeth: these are generally very large, and are stretched out and held even by a frame.

The workmen who make the greatest use of the saw, are the sawyers, carpenters, joiners, cabinet-makers, ebonists, stone-cutters, carvers, sculptors, &c. The lapidaries too have their saw, as well as the workers in mosaic; but these bear little resemblance to the common-saw. But of all mechanics, none have so many saws as the joiners; the chief are as follows; the pit-saw, which is a large two-handed saw, used to saw timber in pits; this is chiefly used by the sawyers. The whip-saw, which is also two handed, used in sawing such large pieces of stuff as the hand-saw will not easily reach. The hand-saw, which is made for a single man's use, of which there are various kinds; as the bow or frame-saw, which is furnished with cheeks: by the twisted cords which pass from the upper parts of these cheeks and the tongue in the middle of them, the upper ends are drawn closer together, and the lower set further apart. The tenon-saw, which being very thin, has a back to keep it from bending. The compass saw, which is very small, and its teeth usually not set: its use is to cut a round, or any other compass-kerf: hence the edge is made broad and the back thin, that it may have a compass to turn in.

The surgeons also use a saw to cut off bones; this should be very small and light, in order to be managed with the greater ease and freedom, the blade exceeding fine, and the teeth exquisitely sharpened, to make its way more gently, and yet with great expedition, in cutting off legs, arms, &c.

SAW-FISH, in ichthyology, a species of *squalus*, with the rostrum very long, flat, and dentated on both sides.

It is one of the most singular animals of the fish kind, and grows to a considerable size, being often more than twelve feet in length, including the rostrum, and very thick in proportion: the head is large, and terminates in a bony rostrum, three or four feet, or more, in length, and furnished all along, on both sides, with very long, robust, and sharp teeth, or denticulations.

SAWING, dividing timber, &c. by the application of a saw, either by the hand or mill.

The mechanism of a sawing mill may be reduced to three principal things; the first, that the saw be drawn up and down as long as is necessary, by a motion communicated by water to the wheel: the second, that the piece of timber to be cut into boards be advanced by an uniform motion to receive the strokes of the saw; for here the wood is to meet the saw, and not the saw to follow the wood; therefore the motion of the wood and that of the saw ought immediately to depend the one on the other: the third, that when the saw has cut through the whole length of the piece, the whole machine stops of itself, and remains immovable; for fear, lest having no obstacle to surmount, the force of the water should turn the wheel with too great rapidity, and break some part of the machine. In plate CXI. we have given several views of this mill: *fig. 1.* represents a section of it taken lengthwise from A to B.

Fig. 2. *ibid.* is a plan of the mill on a level with the ground: A B being the floor, and *ff, gg*, two grooves for receiving the shafts of the chariot, which carries the piece to be sawed; by which means the piece not only advances with the chariot, but is also kept steady, so that the strokes of the saw work always on the same line.

Fig. 3. represents the breadth of the mill: and *fig. 4.* *ibid.* the plan of the cave of the mill. In each of these figures the same letters express the same parts, only represented in a different view: thus M N, in *fig. 1.* and 3. *ibid.* represent the great wheel turned by a fall of the water, which has five feet and a quarter of radius, and its arbor is sixteen inches. O, in each of the figures, is the cog wheel turning on the same arbor with the great wheel, and inserting its teeth into the spindles of the trundle-head P; and, on the other, into those of the trundle-head R: in the trundle-head P there is a broad crank fastened to the iron-blade *y*, (plate CXI. *fig. 1.*) which, as the trundle-head moves round, goes up and down, and gives the same motion to the saw T: this crank is seen in its true form at Q, (plate CXI. *fig. 3.* and 4.) The other trundle-head, R, which turns with its axle-tree, or roller, S, (*ibid. fig. 4.*) winds up a rope, which brings towards the saw the chariot *r*, (pl. CXI. *fig. 1.*) on which the piece of wood to be sawed is placed. When the wood is arrived close to the saw, the rope is no longer of use; there being then another moderator, which regulates the motion of the piece in proportion as it is sawed. Z, (plate CXI. *fig. 3.*) is a cramp-wheel, containing three hundred and eighty-four hooked teeth, the axis of which wheel drives two small trundle-heads, which are inserted into teeth which line the undermost part of the shafts of the chariot; by which means, if the cramp-wheel advances, the chariot must also advance, and the piece of timber with it.

Upon the upper part of the entortise of the saw, (plate CXI. *fig. 1.*) there is an iron-rod, *b*, fastened to it, on the one end with a hinge, and on the side to a moving lever, *d*, which goes up and down with it; this lever is fastened by a hinge at *a*: from the end of this lever there descends a wooden shaft, which carries at its extremity an iron in the form of a hind's foot, which enters the teeth of the cramp-wheel. In order to understand the use of all these parts, let it be observed, that after the rope, by being wound on the axis of the trundle-head R, has brought the chariot and piece of wood as far as the saw, the trundle-head P is let loose to the cog-wheel, which makes the crank Q, and consequently the saw, go up; which ascending lifts up the lever *d*, which drawing the hinge at *a* the handle protracts itself, and drives farther a notch of the cramp-wheel Z: this cramp-wheel, in turning with its axis, drives round the trundle-heads, which inserting their trundles into the teeth at the bottom of the chariot, carry off some of them, and make the

Fig. 4. A Plan of the Cave of the Mill.

the piece of timber come a little forwards. This is all performed while the saw ascends: and as it is larger at the top than at the bottom, it leaves at that instant an empty space between itself and the piece of wood it has bit. The wood advances without any obstacle, and receives a new stroke in the fall of the saw, which works only in going down; the wheel Z is at that time without any motion, and therefore communicates none to the chariot. It is during that rest of the piece of wood that the stroke of the saw is given; and as the saw is broader at the top than at the bottom, it leans on the length of the wood, which is an ingenious imitation of the sawyers, who bring the saw down obliquely, because the fibres of wood are not easily cut when the stroke is transversal: and as the arms of the saw move backwards and forwards occasionally, to give the saw a proper inclination on the fibres of the wood; thus the upper iron rod, and the iron at the bottom of the saw obey the motion of the lever and crank, so as to form with the saw the inflexions necessary. This motion is continued, and the timber is still brought under the saw, till a band of iron fastened to the extremity of the piece of wood, meets with a trigger which draws out a pin applied to the sluice to keep it up: when the sluice falls the water stops, and the whole machine is without motion.

Sawing-mills are much used abroad, and were lately begun to be introduced in England; but the parliament taking it into consideration that they would spoil the sawyer's trade, and ruin great numbers of families, thought fit to suppress them.

Stones, &c. are also sawed by an engine, the principal parts of which are represented in plate CXII. fig. 1. where I L L I, is a square frame perpendicular to the horizon, moving in the direction L L, in gutters made in the fixed beams A M, C B, and running upon little wheels. I L are two rods of iron, and *op* two hands of iron running along those rods; to these are fixed the saws S, S. H I K is a triangle fixed to the axis of a great wheel. As the wheel and triangle go about from H towards I, the point I acting against the piece G, moves the frame towards M B, together with the saws S, S. When I is gone off, the angle K acts against the piece F, and moves the frame back again. Then H, acting against G, moves it forward; and so the saws are moved backward and forwards, as long as the wheel turns round. As these saws work by the motion of the engine, the hands *op* descend. The parts F and G ought to be made curved; and little wheels may be applied at the points of the triangle to take away the friction against F and G: and if the power be strong enough, the axle of the wheel may be made to carry more triangles, and work more saws. Instead of the triangle H I K, the frame may be moved by the two pieces *a b*, *c d*, going through the axis across one another, so that *a b* may only act on F, and *c d* on G; F being only in the plane of *a b*'s motion, and G in that of *c d*.

SAXIFRAGE, *Saxifraga*, in botany, a genus of plants, with a rosaceous flower, consisting of five plane ovated petals: the fruit is an unilocular capsule, of an oval form, containing a great many seeds.

The tuberosities at the root of the white-flowered saxifrage are kept in the shops under the name of saxifrage-seeds: they are diuretic and attenuant; and therefore good in nephritic cases and obstructions of the menses and viscera: some also recommend them in the jaundice and dropsy.

As to the saxifrage of the ancients, it is not known what plant they meant by it; so that no benefit can be reaped from their accounts of its virtues.

It is also to be observed, that though many different plants have been called saxifrage, from their supposed power of dissolving the stone in the human bladder, yet it is very certain that none of them possess such a virtue: thus the chrysosplenium has been called golden-saxifrage; filipendula, red-saxifrage; and the common melilot, yellow-saxifrage. See the articles CHRYSOSPENIUM FILIPENDULA, &c.

SAY or SAYE, in commerce, a kind of serge, or wool-len-stuff, much used abroad for linings, and by the religious for shirts: with us it is used for aprons by several sorts of artificers, being usually dyed green.

SCABIOUS, *Scabiosa*, in botany, a plant with a flos-culous flower, each floscule being monopetalous and tubular, and slightly divided into four or five segments at the limb: there is no pericarpium; the seeds, which are single after each floscule, being crowned with their proper cups, and contained in the common receptacle.

The leaves of scabious stand recommended as aperient, sudorific, and expectorant; but the present practice has little dependance on these virtues.

SCAFFOLD, among builders, an assemblage of planks and boards, sustained by tressels and pieces of wood fixed in the wall; whereon masons, bricklayers, &c. stand to work in building high walls, &c. and plasterers, in plastering ceilings, &c.

Scaffold also denotes a timber-work raised in the manner of an amphitheatre, for the more commodious viewing any show or ceremony: it is also used for a little stage, raised in some public place whereon to behead criminals.

SCALA, in anatomy, a name given to two canals in the cochlea of the ear.

SCALA, in architecture, the same with stair-case.

SCALADO, or SCALADE, in the art of war, a furious assault made on the wall or rampart of a city, or other fortified place, by means of ladders, without carrying on works in form to secure the men.

SCALE, a mathematical instrument, consisting of several lines drawn on wood, brass, silver, &c. and variously divided, according to the purposes it is intended to serve; whence it acquires various denominations, as the plain scale, diagonal-scale, plotting scale, Gunter's-scale, &c.

Construction and Use of the Plain SCALE. The plain scale is an instrument much used in navigation, &c. for solving the several cases of sailing. See the article NAVIGATION.

Having described the circle D B C A, (plate CXII. fig. 2.) and divided it into four quadrants, by the diameters A B and C D crossing each other at right angles: 1. To project the line of tangents, from the end C of the diameter C D, erect the perpendicular C G; then dividing the arch C B into nine equal parts, from the center E, through the several divisions of the quadrant C B, draw lines till they cut the perpendicular C G, which will thereby become a line of tangents.

2. For the semi-tangents, or half tangents, let lines be drawn from the point D, through the same divisions upon the arch C B; and they will divide the radius B E into a line of semi-tangents, as is evident from Euclid. lib. 3. prop. 20.

3. For the secants, transfer the lines drawn from the center through the several divisions of the quadrant C B to form the line of tangents, to the line E B continued to F, and the line E F will be a line of secants.

4. For the fines, from the several divisions of the quadrant C B, let fall perpendiculars upon the radius C E; which will thereby be divided into a line of fines, to be numbered from E to C for the right fines, and from C to E for the versed fines: and these versed fines may be continued to 180°, if the same divisions be transferred on the other side of the center E.

5. For the chords: the arch C B being divided into nine equal parts, in the points 10, 20, 30, &c. if lines be imagined to be drawn from C to these divisions, they will be the chords of their respective arches; wherefore setting one foot of your compasses in the point C, and transferring the several lengths, C 10, C 20, C 30, &c. to the line C B, it will thereby be divided into a line of chords. These several lines, which in the figure are drawn but to every tenth degree, might in the very same manner be constructed to every degree, if the circle were made large enough to admit of ninety distinct divisions in the arch of one of its quadrants.

6. A line of rhumbs is thus constructed: divide the arch D B into eight equal parts, in the points 1, 2, 3, 4, &c. then setting one foot of the compasses in D, transfer the several distances D 1, D 2, D 3, from the arch to the line D B; which by this means will be divided into a line of rhumbs, each of which will answer to an angle of 11° 15'.

7. To construct a line of longitude, divide the radius E A into sixty equal parts, marking every ten with their

proper numbers; from these divisions let fall perpendiculars upon the arch A D, and having drawn the line A D, with one foot of the compasses in A, transfer the several distances, where the perpendiculars cut the arch to the line A D, which will thereby be divided into a line of longitude.

8. To project the line of latitude, the radius C E being already divided into a line of fines, lay a ruler from the point B through each of the said divisions, and mark the points cut on the opposite arch A C with the numbers 10, 20, 30, &c. then having drawn the line A C, with one foot of your compasses in A, transfer the several intersections of the arch to the said line, which will thereby become a line of latitude.

9. To project the hour line, draw the tangent I K equal and parallel to the diameter C D, and divide half the arch of each quadrant A C, and A D, from the point A, into three equal parts, which will be 15° each part, for the degrees of every hour from twelve to six; each of which parts are to be again subdivided into halves and quarters, &c. then drawing lines from the center E, through each of their divisions and sub-divisions, till they cut the tangent I K, the said tangent will thereby be divided into a line of hours.

10. To the above lines may be added a line of inclination of meridians, which is projected in the same manner as the hour-line; being only divided into degrees, instead of time, every fifteen degrees being equal to an hour.

Now if these lines, with their respective divisions, be transferred to a scale, and there also be added a line of equal parts, the instrument called the plain scale will be completed, as in *fig. 3.* and as to the uses of these lines, those of tangents, semi-tangents, and secants, serve to find the centers and poles of projected circles, in the stereographic projection of the sphere, &c. the line of fines serves for the orthographic projection of the sphere; the line of chords serves either to lay down any angle, or measure the quantity of one already laid down: the line of rhumbs serves with more readiness than the line of chords, to lay down or measure the angle of a ship's course in navigation: the line of longitude being laid down on the scale contiguous to a line of chords of the same radius, and numbered the contrary way, shews by inspection how many miles there are in a degree of longitude in each parallel of latitude; reckoning the latitude upon the line of chords, and the miles of longitude upon the line of longitude: the two lines of latitudes and hours are used conjointly, and serve very readily to mark the hour-lines in the construction of dials, on any kind of upright planes.

Diagonal-SCALE is projected thus: first draw eleven parallel lines at equal distances (see plate CXII. *fig. 4.*) the whole length of which being divided into a certain number of equal parts, according to the length of the scale, by perpendicular parallels, let the first division be again subdivided into ten equal parts, both above and below; then drawing the oblique lines from the first perpendicular below to the first sub-division above, and from the first sub-division below to the second sub-division above, &c. the first space shall thereby be exactly divided into one hundred equal parts; for as each of these sub-divisions is one tenth part of the whole first space or division, so each parallel above it is one tenth of such sub-division, and consequently one hundredth part of the whole first space; and if there be ten of the larger divisions, one thousandth part of the whole scale. If therefore the larger divisions be accounted units, the first subdivisions will be tenth parts of an unit; and the second sub-divisions, marked by the diagonals on the parallels, hundredth parts of an unit. Again, if the larger divisions be reckoned tens, the first sub-divisions will be units, and the second subdivisions tenth parts; and if the larger divisions be accounted hundredths, the first sub-divisions will be tens, and the second units: and so on.

Gunter's SCALE. See GUNTER'S *Scale*.

SCALE, Scala, in music, is a denomination given to the arrangement of the six syllables invented by Guido Aretine, *ut, re, mi, fa, sol, la*, called also gammut. See GAMMUT.

It bears the name scale (i. e. ladder) by reason it represents a kind of ladder, by means whereof, the voice

rises to acute, or descends to grave; each of six syllables being, as it were, one step of the ladder. Scale is also used for a series of sounds rising or falling towards acuteness or gravity, from any given pitch of tune, to the greatest distance that is fit or practicable, through such intermediate degrees as make the succession most agreeable and perfect, and in which we have all the harmonical intervals most commodiously divided. See the article INTERVAL.

This scale is otherwise called an universal system, as including all the particular systems belonging to music. See SYSTEM.

Origin and Construction of the SCALE of Music. Every concord or harmonical interval is resolvable into a certain number of degrees or parts; the octave, for instance, into three great tones, two less tones, and two semi-tones; the greater sixth into two greater tones, one less tone, and two semi-tones; the fifth into two greater tones, one less tone, and one semi-tone; the fourth into one greater tone, one less tone, and one semi-tone; the greater third into one greater tone, and one less tone; and the lesser third into one greater tone and one less tone. It is true, there are variety of other intervals or degrees, besides greater tones, less tones, and semi-tones, into which the concords may be divided; but these three are preferred to all the rest, and these three alone are in use. Farther, it is not any order or progression of these degrees that will produce melody; a number, for instance, of greater tones, will make no music, because no number of them is equal to any concord, and the same is true of the other degrees; there is a necessity, therefore, of mixing the degrees to make music, and the mixture must be such, as that no two of the same kind be ever next each other. See the article CONCORD.

A natural and agreeable order of these degrees, Mr. Malcolm gives us in the following division of the interval of an octave, wherein (as all the lesser concords are contained in the greater) the divisions of all the other simple concords are contained. Under the series are the degrees between each term, and the next. In the first series, the progression is by the less third; in the latter, by the greater third.

Great 2d. gr. 3d. 4th. 5th. 6th. 7th. 8th.

I : $\frac{2}{3}$: $\frac{4}{3}$: $\frac{5}{3}$: $\frac{6}{3}$: $\frac{7}{3}$: $\frac{8}{3}$: $\frac{9}{3}$
fund. Key or tone. great tone. less tone. semi-tone. great tone. less tone. great tone. semi-tone.

Great 2d.

I : $\frac{2}{3}$: $\frac{4}{3}$: $\frac{5}{3}$: $\frac{6}{3}$: $\frac{7}{3}$: $\frac{8}{3}$: $\frac{9}{3}$
fund. Key or tone. great tone. semi-tone. less tone. great tone. semi-tone. great tone. less tone.

Now the system of octave containing all the original concord, and the compound concords being only the sums of the octave and some less concord; it is evident that, if we would have the series of degrees continued beyond an octave, there to be continued in the same order through a second as through the first octave; and so on through a third and a fourth octave, &c. and such a series is what we call the scale of music.

Of this there are two different species, according as the less or greater third, or the less or greater sixth are taken in; for both can never stand together in relation to the same key or fundamental, so as to make an harmonical scale. But, if by either of these ways, we ascend from a fundamental or given sound to an octave, the succession will be melodious, though the two make two different species of melody. Indeed, every note is discerned with regard to the next; but each of them is concord to the fundamental, except the second and seventh. In continuing the series there are two ways of compounding the names of the simple interval with the octave; thus a greater or lesser tone, or semi-tone, above an octave or two octaves, &c. or to call them by the number of degrees from the fundamental, as ninth, tenth, &c.

In

In the two scales above, the several terms of the scale are expressed, by the proportionable sections of a line represented by 1. the key or fundamental of the series. If we would have the series expressed in whole numbers, they will stand as follows, in each whereof the greatest number expresses the longest chord, and the other numbers the rest in order; so that, if any number of chords be in these proportions of length, they will express the true degrees and intervals of the scale of music, as contained in an octave concinnously divided in the two different species above-mentioned.

540 : O great tone.	480 : O less tone.	432 : 4 semi- tone.	405 : 5 great tone.	360 : O less tone.	324 : 4 great tone.	288 : 3 less tone.	270 : 2 semi- tone.
216 : 2 great tone.	192 : 1 semi- tone.	180 : 1 less tone.	162 : 2 great tone.	144 : 1 semi- tone.	135 : 3 great tone.	120 : 2 less tone.	108 : 1 semi- tone.

This scale the antients called the diatonic scale, because proceeding by tones and semitones.

The moderns call it simply the scale, as being the only one now in use; and sometimes the natural scale, because its degrees and their order are the most agreeable and concinnous, and preferable, by the consent both of sense and reason, to all other directions ever instituted. Those others are the chromatic and enharmonic scales, which, with the diatonic, made the three scales or genera of melody of the antients.

The design of the scale of music is to shew how a voice may rise and fall less than any harmonical interval, and thereby move from one extreme of any interval, to the other, in the most agreeable succession of sounds. The scale, therefore, is a system exhibiting the whole principles of music; which are either harmonical intervals (commonly called concords) or concinnous intervals. The first are the essential principles, the other subservient to them, to make the greater variety.

Accordingly, in the scale we have all the concords with their concinnous degrees so placed, as to make the most perfect succession of sounds from any given fundamental or key, which is supposed to be represented by 1. It is not to be supposed that the voice is never to move up and down by any other more immediate distances than those of the concinnous degrees; for though that be the most usual movement, yet, to move by harmonical distances, as concords, at once, is not excluded, but is even absolutely necessary. In effect, the degrees were only invented for variety's sake, and that we might not always move up and down by harmonic intervals, tho' those are the most perfect, the others deriving all their agreeableness from their subserviency to them. See the article CONCORD.

Add, that besides the harmonical and concinnous intervals, which are the immediate principles of music, and are directly applied in practice; there are other discord relations which happen unavoidably in music in a kind of accidental and indirect manner; for, in the succession of the several notes of the scale, there are to be considered, not only the relations of these that succeed others immediately, but also of those betwixt which other notes intervene. Now the immediate succession may be conducted so as to produce good melody, and yet among the distant notes there may be very gross discords that would not be allowed in immediate succession, much less in consonance. Thus, in the first series or scale above delivered, though the progression be melodious, as the terms refer to one common fundamental, yet are there several discords among the mutual relations of the terms; e. gr. from 4th to 7th is 32 : 45, and from the greater 2d to the greater 6th is 27 : 40, and from the greater 2d to 4th is 27 : 32, which are all discords; and the same will happen in the second series.

SCALE, in geography and architecture, a line divided into equal parts, placed at the bottom of a map, or plan, to serve as a common measure for all the parts of the building, or all the distances and places of the map.

SCALENE, or SCALENOUS TRIANGLE, *Scalenum*, in geometry, a triangle whose sides and angles are unequal.

SCALENUS, in anatomy, a name given to one of the flexors of the neck. This muscle has its origin from the first, second, and sometimes the third rib; and is inserted into the apophyses of the vertebræ of the neck, and is by some justly referred to the number of the elevators of the thorax. The scalenus is frequently divided into three parts; hence some anatomical writers have made three muscles of it under the names of the first, the second, and the third scalenus.

SCALPEL, in surgery, a kind of knife used in anatomical dissections and operations in surgery.

SCALPER, or SCALPING-IRON, a surgeon's instrument used for scraping foul carious bones.

SCAMMOMY, in the materia medica, is a concreted vegetable juice of a plant of the same name, partly of the resin and partly of the gum-kind, of which there are two sorts, distinguished by the names of the places from whence they are brought.

The Aleppo scammony is of a spongy texture, light and friable: it is of a faint disagreeable smell, and its taste is bitterish, very nauseous, and acrimonious. The Smyrna scammony is considerably hard and heavy, of a black colour, and of a much stronger smell and taste than the former, otherwise it much resembles it.

In general, scammony is to be chosen friable and easily powdered, glossy when fresh broken; such as grows white on being moistened with the spittle; free from dirt, sand, or other foulnesses, and not too violently acrimonious in its taste. Scammony is in great esteem and frequent use, and would be more so, if it were more to be depended upon: but there is so much difference in the purgative virtue of some masses of it, and that of others, that it is seldom to be depended upon alone in extemporaneous practice. It is, however, an ingredient in many compositions of the shops; and these are prescribed, with other cathartics, for purging off serous humours. It is, in general, however, a better purge for robust people than for those of more delicate constitutions, though with the correctives with which it is joined, it is given with safety and success to children. The chemical writers have given us many preparations of scammony, among which are a tincture and a resin; but the scammony in substance is preferable to either; for they both irritate more, and yet purge less; the resin itself given in an equal dose with the crude scammony, will give fewer stools, and those attended with worse gripings. The ancients used scammony externally for cutaneous eruptions, and to soften hard tumours; but at present it is used only as a purge.

SCANDALUM MAGNATUM, in law, is a defamatory speech or writing to the injury of a person of dignity; for which a writ that bears the same name is granted for the recovery of damages. By statute, no person is either by writing or speaking to publish any false or scandalous news of any lord, prelate, officer of the government, judge, &c. on pain of imprisonment, till he produce his author; and if the same be published in a libel, the publisher is indictable, and may be fined and imprisoned.

SCANNING, *Scansio*, in poetry, the measuring of a verse by feet, in order to see whether or no the quantities be duly observed.

SCANTLING, in ship building, is the breadth and thickness of a piece of timber.

SCAPE-GOAT, in Jewish antiquity, the goat which was set at liberty on the great day of expiation. See EXPIATION.

Spencer is of opinion, that the scape-goat was called Azazel, because it was sent to Azazel, i. e. the devil; the reasons of which ceremony, he takes to be these. 1. That the goat, loaded with the sins of the people, and sent to Azazel, might denote the miserable condition of sinners. 2. The goat was sent thus loaded to the dæmons, to shew that they were impure, and to deter the people from worshipping them. 3. That the goat sent to Azazel sufficiently expiating the sins of the Israelites, they might the more willingly abstain from the expiatory sacrifices of the heathens.

SCAPULA, in anatomy, the shoulder-blade, a triangular bone, situated on the outside of the ribs, and com-

commonly extended from the second to the seventh rib; its superior posterior angle, when it is in the least straining position, being about three inches from the spinal processes of the vertebræ. while the long side between that angle and the inferior one is stretched obliquely forward as it descends, having nothing between it and the ribs except the thin extremities of some muscles; but as the scapula advances forwards to its articulation with the arm bone, its distance from the ribs increases.

In the examination of the scapula, says Heister, we are to observe the head of the bone, with its glenoid cavity, called by some the acetabulum of the scapula; its neck; its base; its two angles, the superior and inferior: its superior and inferior costæ; its anterior surface, which is smooth and concave; and its posterior, which is uneven. After these we are to observe its spine, its crest, and its acromion; its supra and infra spinate cavity; its coracoid process; and its two incisures, the one between the neck and the acromion, the other behind the coracoid process; and the robust ligament which joins the acromion and the coracoid process, and prevents the luxation of the os humeri upwards.

The uses of the scapula are to sustain the arms, and join them to the body, to serve for the insertion of several muscles, and to add somewhat to the necessary defence of the parts contained within the thorax.

SCAPULAR, *Scapulares*, in anatomy, a name given to two pair of arteries and as many veins. The arteries are the external scapular artery, which is sent from the subclavians to the external parts of the scapula; and the internal scapular artery, which arises from the axillary arteries, and goes to the parts that lie under the scapula. The scapular veins, which are also external and internal, arise in like manner from the subclavians.

SCAPULAR, or SCAPULARY, a part of the habit of several religious orders in the church of Rome, worn over the gown, as a badge of peculiar veneration for the blessed Virgin. It consists of two narrow breadths or slips of cloth, covering the back and breast, and hanging down to the feet.

SCAPUS, in architecture, the fust or shaft of a column.

In botany, the same word is used for the straight stalk or stem of a plant, standing upright like a pillar or column.

SCAR, or ESCHAR, the seam or mark of a wound after it is healed.

SCARABÆUS, the BEETLE, in zoology, a numerous genus of insects, of the coleoptera-order: the antennæ of the beetles are of a clavated figure, and fissile longitudinally; and their eggs all hatch into hexapode worms, from which the young beetles are afterwards produced.

SCARFING, or scarfing, in ship building. When two pieces of timber are joined together, so that the end of one goes over the end of the other, being tapered, so that the one may be let into the other, and become even, they are said to be scarfed: such are the keel-pieces. But when the ends of the two pieces are cut square and put together, they are said to butt one another; and when another piece is laid upon, and fastened to both, as is the case in all the frame-timbers, this is called scarfing the timbers; and half the piece which fastens the two timbers together is reckoned the length of the scarf. *Murray's Ship-Building.*

SCARIFICATION, in surgery, the operation of making several incisions in the skin by means of lancets, or other instruments, particularly the cupping-instrument. See CUPPING.

With regard to the usefulness of scarification, Heister observes, that as much and as thick blood may be discharged this way as by phlebotomy, and that of consequence it must be equally beneficial in all disorders which require bleeding. Besides, scarification is highly necessary in violent inflammations, incipient or confirmed mortification, pestilential carbuncles, and the like, in order to discharge the stagnant and vitiated blood, by making many small wounds or incisions with a scalpel or lancet. Heister also thinks scarification of the gums, in the tooth-ach,

may not unfrequently be very useful; as of the eyes in many disorders, if performed with caution.

SCARLET, a beautiful bright red.

In painting in water colours, minium mixed with a little vermillion produces a good scarlet: but if a flower in a print is to be painted of a scarlet-colour, the lights as well as the shades should be covered with minium, and the shaded parts finished with carmine, which will produce an admirable scarlet.

To dye cloth, stuff, &c. a scarlet, let the stuffs be alumed, as for crimson, in river-water; boil them for two hours, then hang them out a whole night without rinsing; but in the morning rinse them out. Then, in order to dye them, take clean bran-water clean skimmed, and for every pound of goods put in an ounce of pulverized tartar; having first mixed one half of it with half an ounce of cochineal, and when the liquor where the remaining half of the tartar is has boiled, then put in the cochineal, &c. Boil them together, afterwards add half an ounce of aqua fortis, in which a small quantity of sal armoniac (not bigger than a pea) has been dissolved; which must be put in when the stuffs have boiled about a quarter of an hour; then boil them together for a little while, let the liquor cool, and rinse out the stuffs.

To dye a scarlet in grain, take stale clear wheat-bran liquor, a sufficient quantity; alum, three pounds; enter twenty yards of broad-cloth, and boil it three hours; cool and wash it; take fair water, a sufficient quantity; hedder or strawel, a fit quantity; boil them well; cool them with a little water, enter your cloth and make a bright yellow; cool and wash it again; take fresh wheat-bran liquor, a sufficient quantity; madder, four pounds; enter your cloth at a good heat; handle it to a boiling, cool and wash it well: take more fresh bran-liquor; cochineal in fine powder, five ounces; and tartar, three ounces; enter your cloth, and boil an hour or more, keeping it under the liquor, then cool and wash it.

SCARLET-FEVER, the same with miliary fever. See MILIARY FEVER.

SCARP, in fortification, is the interior talus, or slope of the ditch next the place, at the foot of the rampart.

SCARP, in heraldry, the scarf which military commanders wear for ornament.

SCAVAGE, a toll or custom antiently exacted by mayors, sheriffs and bailiffs of cities and towns-corporate, and of merchant-strangers, for wares exposed and offered to sale within their liberties; which was prohibited by 19 Hen. VII. But the city of London still retains this custom.

SCENE, *Scena*, in its primary sense, denoted a theatre, or the place where dramatic pieces, and other public shews were exhibited; for it does not appear that the antient poets were at all acquainted with the modern way of changing the scenes in the different parts of the play, in order to raise the idea of the persons represented by the actors being in different places.

The original scene for acting of plays was as simple as the representations themselves; it consisted only of a plain plot of ground proper for the occasion, which was in some degree shaded by the neighbouring trees, whose branches were made to meet together, and their vacancies supplied with boards, sticks, and the like; and to complete the shelter, these were sometimes covered with skins, and sometimes with only the branches of other trees newly cut down, and full of leaves. Afterwards more artificial scenes or scenical representations were introduced, and paintings used instead of the objects themselves. Scenes were then of three sorts, tragic, comic, and satyric. The tragic scene represented stately magnificent edifices, with decorations of pillars, statues, and other things suitable to the palaces of kings: the comic exhibited private houses with balconies and windows, in imitation of common buildings: and the satyric was the representation of groves, mountains, dens, and other appearances; and these decorations either turned on pivots, or slid along grooves, as those in our theatres.

To keep close to nature and probability, the scene should never be shifted from place to place in the course of the play: the ancients were pretty severe in this respect,

spea, particularly Terence, in some of whose plays the scene never shifts at all, but the whole is transacted at the door of some old man's house, whither, with inimitable art, he occasionally brings the actors. The French are pretty strict with respect to this rule; but the English pay very little regard to it.

Scene is also a part or division of a dramatic poem. Thus plays are divided into acts, and acts are again subdivided into scenes; in which sense the scene is properly the persons present at, or concerned in the action on the stage at such a time: whenever, therefore, a new actor appears, or an old one disappears, the action is changed into other hands; and therefore a new scene then commences.

It is one of the laws of the stage, that the scenes be well connected; that is, that one succeed another, in such a manner as that the stage be never quite empty till the end of the act.

SCENIC GAMES, among the ancients, were entertainments exhibited on the *scena* or theatre, including plays, dancing, and other theatrical performances.

The Romans were four hundred years without any scenic games; and at their institution some actors were sent for from Hetruria; who, without reciting any thing, danced to the sound of instruments; at length they began to rehearse verse, from thence they proceeded to plays, and thus by degrees, growing more and more perfect, their scenical shews were at last represented, with a justness and magnificence beyond every thing the world had ever seen.

SCENOGRAPHY, in perspective, the representation of a body on a perspective plane; or, a description thereof in all its dimensions, such as it appears to the eye.

The ichnography of a building, &c. represents its plan, or ground-work; the orthography, is a view of the front, or one of its sides; and the scenography, is a view of the whole building, front, sides, height, and all, raised on the geometrical plan.

To exhibit the scenography of any body, 1. Lay down the basis, ground-plot, or plan of the body, according to the method taught under the article PERSPECTIVE. 2. Upon the several points of the plan, raise the perspective heights: thus will the scenography of the body be completed, excepting that a proper shade is to be added. The method of raising the heights is as follows: on any point, as C (plate CXII. fig. 5.) to raise a perspective altitude, answerable to an objective altitude PQ; on the terrestrial line raise a perpendicular PQ, equal to the given objective altitude; from P and Q, to any point as T, draw right lines PT and QT; from the given point C, draw a right line CK, parallel to the terrestrial line DE, and meeting the right line QT in K; and in the point K, upon the line KC, erect a perpendicular IK, which will be the scenographic altitude required.

The application of this general method of drawing the scenography of a body, is not so obvious, in every case, but that it may be necessary to illustrate it by a few examples.

Example I. To exhibit the scenography of a cube, viewed by an angle: 1. As the basis of a cube viewed by an angle, standing on a geometrical plane is a square, viewed by an angle; draw a square, viewed angular-wise, on the perspective table, or plane. 2. Raise the side HI (fig. 6.) of the square perpendicularly on each point of the terrestrial line DE; and to any point, as V, of the horizontal line HR, draw the right line VI and VH. 3. From the angles d, b, and c, draw c1, d2, &c. parallel to the terrestrial line DE. 4. From the points 1 and 2, raise L1 and M2 perpendicular to the same. Lastly, since HI is the height to be raised in a, L1 in c and b, and M2 in d; in a raise the line fa perpendicular to aE; in b and c, raise bg and ce perpendicular to bc1; and, lastly, raise db perpendicular to d2, and make af = HI, bg = ec = L1, and hd = M2; if then the points g, b, e, f, be connected by right lines, the scenography will be compleat.

Example II. To exhibit the scenography of a hollow quinquangular prism. 1. Since the base of a hollow quinquangular prism, standing on a geometrical plane, is a pentagon, with a limb or breadth of a certain dimension, find the appearance of this pentagon on a table, or plane. 2. On any point, as H, of the ter-

restrial line DE (fig. 7.) raise a perpendicular HI, equal to the objective altitude, and to any point, as V, of the horizontal line HR, draw the lines HV and IV. 3. From the several angles a, b, d, e, c, of the perspective ichnography, both the internal and external ones, draw right lines, as b2, d3, &c. parallel to the terrestrial line; and from the points 1, 2, 3, raise perpendiculars to the same, as L1, M2, m2, N3, n3. If these then be raised in the correspondent points of the ichnography, as in the preceding article, the scenography will be compleat.

Example III. To exhibit the scenography of a cylinder. 1. Since the base of a cylinder, standing on a geometrical plane, is a circle, seek the appearance of a circle; in the points a, b, d, f, b, g, e, c, (fig. 8.) raise the apparent altitudes, as in the preceding articles. If now their upper lines be connected by curve lines, in the base a, b, d, f, c, b, e, c, the scenography of their circle will be compleat.

It is evident that those lines are to be omitted, both in the plan and in the elevation, which are not exposed to the eye; though they are not to be disregarded from the beginning, as being necessary for the finding of other lines; e. gr. in the scenography of the cube, viewed angular-wise, the lines bd and de (fig. 6.) in the base, and the line db in the elevation, are hid from the eye, and are therefore omitted in the description. But, since the point H is not to be found, unless the point d be had in the ichnography, nor the lines gb and de be drawn without the height db, the appearance of the point d is as necessary to be determined in the operation, as the height bd.

Example IV. To exhibit the scenography of a pyramid standing on its base. Suppose, e. gr. it were required to delineate a quadrangular pyramid, viewed by an angle: 1. Since the base of such pyramid is a square seen by an angle, draw such a square. 2. To find the vertex of the pyramid, i. e. a perpendicular let fall from the vertex to the base, draw diagonals mutually intersecting each other in e (fig. 9.) 3. On any point, as H, of the terrestrial line DE, raise the altitude of the pyramid HI; and, drawing the right lines HV and IV to each point of the horizontal line HR, produce the diagonal hb, until it meet the line VH in b. Lastly, from b draw bi parallel to HI. This, being raised on the point e, will give the vertex of the pyramid K; consequently the lines dK, Kc, and Kb, will be determined at the same time. After the like manner is the scenography of a cone delineated.

Example V. To exhibit the scenography of a truncated pyramid. Suppose the truncated pyramid quadrangular: first then, if from the several angles of the upper base be conceived perpendiculars, let fall to the lower base, we shall have a pentagon, with another inscribed therein, whose sides are parallel to those of the former; this coincides with a pentagon, furnished with a rim or breadth, &c. and may therefore be delineated in the same manner. 2. Raising the altitude of the truncated pyramid IH (fig. 10.) determine the scenographic altitudes to be raised in the points a, b, c, d. If now the points f, g, b, i, k, be connected by right lines, and the lines bk, fm, gn, be drawn, the scenography will be compleat. By drawing two concentric circles in a geometrical plane, and doing every thing else, as in this problem, the scenography of a truncated pyramid will be drawn.

Example VI. To exhibit the scenography of walls, columns, &c. or to raise them on a pavement. 1. Suppose a pavement AF, HI (fig. 11.) represented in a plan, together with the bases of the columns, &c. if there be any. 2. Upon the terrestrial line set off the thickness of the wall BA and 1, 3. Upon A and B, as also upon 3 and 1, raise perpendiculars AD and BC, as also 3, 6, and 1, 7. 4. Connect the points D and 6 with the principal point V, by the right lines DV and 6V. 5. Upon F and H raise perpendiculars HG and EF. Thus will all the walls be delineated. Now to raise the pillars, &c. there needs nothing but from their several bases (whether square or circular) projected on the perspective plan, to raise the indefinite perpendiculars; and on the fundamental line, where intersected by the radius Fa passing through the base, raise the true altitude AD; for DV, being drawn as before, the scenographical altitudes will be determined.

Example VII. To exhibit the scenography of a door in a building. Suppose a door required to be delineated in a wall D E F A (*fig. 11.*) 1. Upon the fundamental line set off its distance A N from the angle A, together with the breadths of the posts N I and L M, and the breadth of the gate itself L I. 2. To the point of distance K, from the several points N, I, L, M, draw right lines K N, K I, K L, K M, which will determine the breadth of the door *li*, and the breadths of the posts *in* and *ml*. 3. From A to O set off the height of the gate A O, and from A to P, the height of the posts A P. 4. Join O and P with the principal point by right lines P V and O V. 5. Then, from *n, i, l, m*, raise perpendiculars, the middle ones whereof are cut by the right line O V in *o*, and extremes, by the right line V P in *p*. Thus will the door be delineated, with its posts; if the door were to have been exhibited in the wall E F G H, the method would be nearly the same: For, 1. Upon the terrestrial line, set off the distance of the door from the angle, and thence also the breadth of the door R T. 2. From R and T draw right lines to the principal point V, to have the breadth *rt* in the perspective plan. 3. From *r* and *t* raise indefinite perpendiculars to F H. 4. From A to O set off the true height A O. Lastly, from O to the principal point V draw the right line O V, intersecting E F in *z*, and make *rr* and *tt* equal to F z. Thus is the door *rr, tt*, drawn, and the posts are easily added, as before.

Example VIII. To exhibit the scenography of windows in a wall.—When you know how to represent doors, you will find no difficulty in adding windows; all that is here further required, being to set off the height of the window from the bottom of the ground. The whole operation is as follows: 1. From 1 to 3, set off the thickness of the wall at the window; from 3 to 4, its distance from the angle 3; and from 4 to 5, its breadth. 2. From 4 and 5, to the point of distance L, draw the right lines L 5 and L 4, which will give the perspective breadth 10, 9 of the window. 3. From 10 and 9, raise perpendiculars to the pavement, that is, draw indefinite parallels to 6, 3. 4. From 3 to 11, set off the distance of the window from the pavement 3, 11, and from 11 to 12, its height 11, 12. Lastly, from 11 and 12, to the principal point V, draw the lines V 11 and V 12, which intersecting the perpendiculars 10, 13, and 9, 14, in the points 13 and 14, as also in 15 and 16, will exhibit the appearance of the window.

From these examples, which are only applications of the first grand rule, it will be easily perceived what method to take to delineate any other object, and at any height from the pavement.

SCENOPEGIA, in Jewish antiquity, the same with the feast of tabernacles.

SCEPTER, a kind of royal staff, or battoon, borne by kings, on solemn occasions, as an ensign of command and authority.

SCEPTER, in astronomy, one of the six new constellations of the southern hemisphere, consisting of seventeen stars.

SCEPTICISM, the doctrines and opinions of the Sceptics, whose distinguishing tenet was, that all things are uncertain and incomprehensible, and that the mind is never to assent to any thing, but to remain in perpetual doubt and suspense. This doctrine was also called Pyrrhonism, from the name of its author.

SCHEAT, or **SEAT**, a fixed star of the second magnitude, in the juncture of the leg with the left shoulder of Pegasus.

SCHUCHZERIA, in botany, a genus of plants, having no corolla; the fruit consists of three roundish compressed inflated bivalve reflexo-distant capsules; the seed is single and oblong; there are sometimes six germina, and as many capsules, but three is the more natural and usual number.

SCHINUS, in botany, a genus of plants, the corolla whereof consists of five patent petals; the fruit is a globose berry, containing a large globose single seed.

SCHISM, a separation, or breaking off from communion with any church; on account of some disagreement in matters of faith or discipline.

Ecclesiastical history presents us with a view of several considerable schisms, in which large bodies of men separated from the communion of the church. Such were in the fourth century the schisms of the Donatists, and the many sects that sprung up in the church, as the Photinians, Apollinarians, &c. the schism of the church of Antioch, occasioned by Lucifer, bishop of Cagliari, in Sardinia; in the fifth century, the schism of the church of Rome, between Laurentius and Symmachus; in the ninth century, the separation of the Greek church from the Latin; and particularly the grand schism of the popes of Rome and Avignon, in the fourteenth century, which lasted till the end of the council of Pisa, in 1409.

The Romanists reckon thirty-four schisms in their church, and bestow the name English schism on the Reformation in this kingdom. Those of the church of England, again, apply the term schism to the separation of the nonconformists, viz. the presbyterians, independents, quakers, &c. who contend for a further reformation.

SCHOLASTIC, σχολαστικος, something belonging to the schools. See **SCHOOL**.

Scholastic was a long time a title of honour, at first only given to such as distinguished themselves by their eloquence in declaiming, &c. After Nero, this appellation was bestowed upon advocates, and afterwards it became restrained to such as had the government of ecclesiastical schools, established under the first race of French kings, who instructed the clerks of the church first in the humanities, then in theology and the liturgy. Among the Greeks, this was the name of an office or dignity answering to our divine or theologue.

Scholastic divinity is that part or species of divinity which clears and discusses questions by reason and arguments, in which sense it stands, in some measure, opposed to positive divinity, which is founded on the authority of fathers, councils, &c. The school-divinity is now fallen into the lowest contempt, and is scarce regarded any where, but in some of the universities, where they are still by their charters obliged to teach it.

SCHOLIAST, or **COMMENTATOR**, a grammarian, who writes scholia, that is, notes, glosses, &c. upon antient authors, who have written in the learned languages.

SCHOLIUM, a note, annotation, or remark, occasionally made on some passage, proposition, or the like. This term is much used in geometry, and other parts of mathematics, where after demonstrating a proposition, it is customary to point out how it might be done some other way, or to give some advice, or precaution, in order to prevent mistakes, or add some particular use, or application thereof.

SCHOOL, *Schola*, a public place, wherein the languages, humanities, or other arts and sciences are taught. Thus we say, grammar-school, writing-school, &c.

SCHOONER, in navigation, a vessel navigated with two masts, and two large boom-sails on the main and fore-masts, besides the usual small sails. They are generally built very light, as being principally intended for swiftness, and to sail in seas which are seldom frequented with stormy weather; such are the latitudes between or near the tropics.

The largest vessels of this kind are built in the island of Bermuda, where they are framed of cedar.

SCHWALBEA, in botany, a genus of plants, the corolla whereof consists of a ringent single petal, the tube is of the length of the cup, the limb is erect, the superior lip is erect, concave, and quite entire, the lower one is trifid and obtuse; the fruit is either a bilocular capsule, or there is no pericarpium; the seed is single, roundish, and small.

SCIÆNA, in ichthyology, a genus of fishes; the whole head and covering of the gills are scaly, and one of the laminæ of these coverings serrated at the edges; the body is compressed and broad, the back is acute, there are teeth in the jaws and fauces, the palate and tongue are smooth; there is only one fin on the back, which is divided in the middle to the very base; the tail is equal at the extremity; this genus comprehends the umbra and the umbrino.

SCI-

SCIARRI, in natural history, the matter which runs down in burning torrents from the craters of volcanos, and which probably contains mineral and metallic particles, it being ponderous and hard.

Some of the sciarrs are coarse, and others fine and polished on the surface; some of them are black, others grey, others reddish, and others of the colour of iron; and many of them have coverings of pure sulphur over their whole surface. They seem to be the result of many sorts of minerals melted together.

SCIATICA, the **HIP-GOUT**, a violent and obstinate pain in the hip, chiefly in the joint, where the head of the thigh-bone is received into the acetabulum of the coxendix. This pain will sometimes extend itself to the lower part of the loins, to the thigh, leg, and even the extremity of the foot, yet outwardly there is no swelling, no inflammation, nor change of colour in the skin; sometimes there is such a spasm of the muscles on the side affected, that the patient cannot stand upright without the utmost pain. When the sciatica has continued very long, there is such a collection of pituitous humour in the cavity of the joint, that by relaxing the ligaments, it often causes a luxation. Sometimes it causes an aridura, or wasting away of the adjacent parts. When the pain leaves the hip, and moves downwards, it is a sign that the spasms are resolved; a violent motion of the body generally exasperates the pain. This disorder may arise from the same cause with that which produces the gout; but it is most generally the effect of catching cold, or being exposed to the open air; it may also be occasioned by contusions and venereal disorders.

After a gentle cathartic, or clyster, bleeding will be proper, especially in the ankle; also leeches applied to the hæmorrhoidal veins, have been found beneficial; strong purges are hurtful, but mercurius dulcis with scammony, or some other purgative, will be of service; some give mercurial emetics, and afterwards mercurial purgatives, repeated twice a week, or as occasion requires, for six times. If the patient is old, lenient purgatives will be most proper, and on intermediate days a dose of calomel, which is afterwards to be purged off, and so repeated alternately for some time. Outwardly, the linimentum saponaceum is recommended by Riverius, Junker, and others; the part is to be anointed with it near the fire. Riverius says, he has known an obstinate sciatica cured in one day, by applying six cupping glasses on and about the part affected, and then anointing it with oil of bricks hot, and afterwards covering it with a linen-cloth, made very hot. Zacutus Lusitanus affirms, that the sciatica has been cured in a few hours, by applying eight or ten leeches to the part affected. Baglivi observes, that if nothing else will do, recourse must be had to caustics, particularly the leaves of ranunculus, or a mixture of quick lime, and soft soap.

SCIENCE, *Scientia*, in philosophy, denotes any doctrine, deduced from self-evident and certain principles, by a regular demonstration.

Science may be properly divided as follows: 1. The knowledge of things, their constitutions, properties, and operations; this, in a little more enlarged sense of the word, may be called *φυσική*, or natural philosophy; the end of which is speculative truth.

2. The skill of rightly applying these powers, *πρακτική*; the most considerable under this head is ethics, which is the seeking out those rules and measures of human actions that lead to happiness, and the means to practise them; and the next is mechanics, or the application of the powers of natural agents to the uses of life.

3. The doctrine of signs, *σημειωτική*; the most usual of which being words, it is aptly enough termed logic.

This, says Mr. Locke, seems to be the most general, as well as natural, division of the objects of our understanding. For a man can employ his thoughts about nothing but either the contemplation of things themselves for the discovery of truth; or about the things in his own power, which are his actions, for the attainment of his own ends; or the signs the mind makes use of, both in the one and the other, and the right ordering of them for its clearer information.

All which three, viz. things, as they are in themselves knowable; actions, as they depend on us in order to

happiness; and the right use of signs, in order to knowledge, being *toto cælo*, different, they seem to be the three great provinces of the intellectual world, wholly separate and distinct one from another.

SCIENTIFIC, or **SCIENTIFICAL**, something relating to the pure, sublimer sciences; or, that abounds in science or knowledge.

SCILLA, **SQUILL**, or **SEA-ONION**, a plant with a large bulbous onion-like root: from which rise, first, a naked stalk, bearing several hexapetalous white flowers, and afterwards large green lily-like leaves with a remarkable rib in the middle of each. It grows spontaneously on sandy shores in Spain and in the Levant, from whence we are annually supplied with the roots. They should be chosen large, plump, fresh, and full of a clammy juice: some are of a reddish colour and others white, but no difference is observed in the qualities of the two sorts, and hence the college allows both to be taken promiscuously.

This root is to the taste very nauseous, intensely bitter, and acrimonious; much handled, it exulcerates the skin. Taken internally, it acts as a powerful attenuant and aperient: in doses of a few grains it promotes expectoration and urine: in somewhat larger ones, it proves emetic and sometimes purgative. It is one of the most certain diuretics in hydropic cases, and expectorants in asthmatic ones, where the lungs or stomach are oppressed by tenacious phlegm, or injured by the imprudent use of opiates.

This medicine, on account of its ungrateful taste, is most commodiously taken in the form of pills; into which the fresh root may be reduced, by beating it with an equal quantity of ammoniacum, and then adding the same quantity of some warm spice, as lesser cardamom-seeds in powder: if the mass should prove too stiff, it is softened with a little balsam of Copaiba. In whatever form squills are given, unless when designed to act as an emetic, the addition of some grateful aromatic material is of use, to prevent the nausea which of themselves they are very apt, even in small doses, to occasion.

The fresh root loses in drying about four fifths of its weight, without any considerable loss of its taste, or virtue; the vapour which exhales appearing to be little other than merely aqueous. Hence four grains, which are the mean dose of the dry root in powder, are equivalent to near a scruple of the fresh squill. The most convenient way of drying it is, after peeling off the outer skin, to cut the roots transversely into thin slices (not to separate the coats as has been usually directed) and expose them to a gentle warmth.

The ancients, in order to abate the acrimony of the squill for certain purposes, enclosed it entire (after separating the skin, and the fibres at the bottom with the hard part from which they issue) in a paste made of flour and water, and then baked it in an oven, till the paste became dry, and the squill soft and tender throughout. The squill, so prepared, was beaten with two thirds its weight of flour, the mixture formed into troches, and dried with a gentle heat. These troches were supposed to be alexipharmic, and in this light were made an ingredient in theriaca, for which purpose they are still retained.

Water, wine, proof spirit, and rectified spirit, extract the virtues both of the fresh and the dry root. Nothing rises in distillation with any of these menstrua, the entire bitterness and pungency of the squill remaining concentrated in the inspissated extracts: the spirituous extract is in smaller quantity than the watery, and of a proportionably stronger almost fiery taste.

Alkalies considerably abate both the bitterness and acrimony of the squill: vegetable acids make little alteration in either, though the admixture of the acid taste renders that of the squill more supportable. These acids extract its virtue equally with watery or spirituous menstrua; and, as an expectorant in disorders of the breast, excellently coincide with it. The college of London directs an acetous tincture to be prepared, by macerating a pound of the dry roots in six pints of vinegar, with a gentle heat: to the liquor, pressed out, and after settling poured off from the fæces, one twelfth its quantity of proof spirit is added, to prevent its growing soon feculent.

feculent. The college of Edinburgh orders fresh squills, cut in thin slices, to be taken in the same quantity as the dry in the above prescription, and the maceration to be continued, in the sun's heat, for forty days. A scillitic oxymel is obtained by boiling a quart of the acetous tincture with three or four pounds of clarified honey, till the mixture acquires the consistence of a syrup. These preparations are used, as expectorants, in doses of one, two, or three drams, along with cinnamon or some other grateful water: where the first passages are overloaded with viscid phlegm, an ounce or more is given at once, to procure a more speedy and effectual evacuation by vomit.

SCIOPTIC, a sphere, or globe of wood, with a circular hole or perforation, wherein a lens is placed. It is so fitted that, like the eye of an animal, it may be turned round every way, to be used in making experiments of the darkened room.

SCIRE-FACIAS, in law, a judicial writ most commonly issued to call a person to shew cause to the court whence it issues, why execution of a judgment passed should not be made out; as where a plaintiff has recovered debt or damages in a court of record, and does not take out execution in a year and a day after judgment recovered; in that case he shall have this writ to summon the defendant to shew cause why execution should not be had against him upon the said judgment; which, if the defendant does not, judgment is given and the plaintiff shall have execution. Where a plaintiff or defendant dies, execution may not be sued out on a judgment till the writ of scire-facias is brought and judgment given thereupon. A scire-facias must likewise issue where judgment is recovered against a femme sole who marries within the year and day, to summon the husband to shew cause, &c. And when a judgment is obtained against a testator, a scire-facias issues against the executor, though within a year after the judgment is had; and also against an administrator to an intestate.

SCIRRHUS, in surgery, a hard tumour without pain, though not absolutely without sensation.

A scirrhus may be produced by whatever is capable of coagulating, inspissating, or drying the liquids in the glands; and, therefore, the scirrhus may be in any of the glands, but especially such as contain an easily inspissated liquor, or from their situation, dispose their contents to a stagnation.

The efficacy of quicksilver, in removing obstructions, is universally known, and both the internal and external use of it has often greatly contributed to the cure of a benign and beginning scirrhus: for when it has acquired a stony hardness, and begins to be malignant, no relief can be expected from the strongest mercurial preparations, nor from a salivation excited by quicksilver, but all the symptoms are rather increased by these means; and, in consequence of the increased motion of the humours, the scirrhus is sooner changed into a cancer. See **CANCER**.

When the scirrhus will not yield to medicines, if its place, situation, adjacent parts, mobility, the state of the disorder, and the strength and condition of the patient permit, it is with all expedition to be totally extirpated with the knife.

SCIRRHUS Hepatis, in medicine, a disease consisting in an indurated tumor of the liver, occasioned by a stagnation of the humours which grow thick there, from an exhalation of their more fluid and subtiler parts.

This differs from the infarctus hepatis, not only in degree but in its symptoms, for it almost always is attended with a hectic, or with cedemato-hydronic swellings.

Signs of it. These are a tumor and hardness in the right hypochondrium, or region of the liver, always evident to the patient, and often sensibly perceived by any body else, on touching the part. To this are to be added dull tense pains, and a sense of weight hanging there, and usually asthmatic symptoms, and a dry cough. It becomes painful to lie on the left, or opposite side; and with these a hectic comes on, with a wasting of the upper parts, and swelling of the inferior ones; first of the feet, but afterwards upwards to the belly, which finally become very obstinate and truly ascitic. The urine in this case is small in quantity, and of a deep orange

colour, and thick consistence. It has usually a muco-sediment, and sometimes a thick one of a rose colour.

Causes of it. These are usually either an omission of artificial discharges of the blood, by habitual bleedings at spring and autumn, or a suppression of the natural ones, by the menses or hæmorrhoidal vessels; an improper treatment of intermitting fevers with astringents, of quartans with large quantities of bark, and of acute fevers with too cooling a regimen, or a violent quantity of the volatile salts, or a condensation of the humours in a simple infarction, by means of cold external applications. The stopping hæmorrhages, which nature had brought on for her relief in plethoras, have also been sometimes known to occasion a scirrhus of the liver; as have also external injuries by blows, falls, and the like.

Prognostics. A recent scirrhus of the liver admits of a cure, but this not without great difficulty, and in a more confirmed one there is very little hope. This tumor has a continual tendency to corruption, either by sphacelation, or by an inflammatory suppuration; neither of which can happen successfully, for the first must occasion instantaneous death, and the latter exulceration, and a succeeding fatal hectic.

A scirrhus of the liver often follows, and sometimes precedes a jaundice of the most violent kind.

Method of treating it. The bowels are first to be cleansed and relaxed by a clyster, made of a decoction of mallows, camomile flowers, mullein, and fennel seed; after this, bleeding in the foot is to be ordered, and then the nitrous and other resolvent medicines are to be given, such as tartar of vitriol, and the like. After this medicated wines should be drank as the common drink, prepared with bryony and arum roots, centaury, hyssop, and maidenhair leaves, saffron, fenna, black hellebore, and rhubarb; and, externally, plasters of the resolvent and strengthening kinds are to be applied. But, after all directions for the treatment, it is to be acknowledged, that an obdurate and inveterate scirrhus admits of no remedy. *Junker's Conf. Med.*

SCISSARS, a well known instrument for cutting any thing asunder. See **FORCEPS**.

SCLEROPHTHALMIA, in medicine, a species of ophthalmia, wherein the eye is dry and inflamed, as are also the eye-brows.

SCLEROTICA, in anatomy, one of the tunics, or coats, of the eye: it is hard, opaque, and extended from the cornea to the optic nerve; its forepart is transparent, and called the cornea.

SCLEROTICS, medicines proper to harden and consolidate the flesh of the parts to which they are applied; as purslain, house-leek, flea-wort, garden-nightshade, &c.

SCOLOPAX, the **WOOD-CK**, in ornithology, a species of numenius, with a black line on each side the head: it is a very beautiful as well as delicate bird, somewhat smaller than the partridge; the upper part of its body being of a mixed colour, mottled with black grey, and a reddish-brown: the breast and belly are a pale-grey, with little transverse lines of a bright brown: the upper part of the throat is of a whitish-yellow, and the hinder part of the head chiefly black, with a few transverse lines of brown on it: the male is somewhat darker than the female, in its general colouring. See **NUMENIUS**.

SCOLOPENDRA, in zoology, an insect with a very slender and long body, and furnished with a vast number of legs.

SCONCE, in fortification, a small field-fort, built for the defence of some pass, or other post. See the article **FORT**.

SCORBUTUS, the **SCURVY**, in medicine. See **SCURVY**.

SCORDIUM, **WATER GERMANDER**, in botany, is comprehended by Linnæus among the teucriums. See **TEUCRIUM**.

It is celebrated for its sudorific and alexipharmic virtues, and is accordingly prescribed in malignant disorders: but it is never used alone, being only kept in the shops as an ingredient of the confectio Fracastorii, which takes its name of diascordium from it.

SCORE,

SCORE is sometimes used to denote the number twenty.

SCORIA, or DROSS, among metallurgists, is the re-crements of metals in fusion; or, more determinately speaking, is that mass which is produced by melting metals and ores, and when cold is brittle, and not dissoluble in water; being properly a kind of glass.

Some authors call by this name that saline mass which is produced by melting ores and metals together with saline and reducing fluxes. But the word *scoria* is not properly to be understood of all this mass, but only of the vitrified particles which are lodged between, and adhere to the small masses of the salts, and which may be separated from them by water.

SCORIFICATION, in metallurgy, is the art of reducing a body, either entirely, or in part, into scoria.

It is used by metallurgists, in order that any metal, imprisoned in any solid body, may on account of its weight, descend and separate itself therefrom; and finally, if that be required, be either wholly or in part converted into scoria. All fixed bodies are subject to this alteration, not totally excepting even gold and silver. There are also, among the volatile bodies, some that may be fixed, and which assume the name of scorix, by adding fixed bodies to them.

It is often proper to make this scorification in a vessel that may absorb the scorix, and retain only the metallic part of the mass under trial. In this case the operation is called coppelling; and vessels made of ashes, called tests and coppels, serve for this purpose. It is evident, in these processes, that a great attenuation of the scorix is necessary, that they may be able to pass through the vessel; nor is there any fitter body to promote this operation than lead, which, by its undergoing itself a like attenuation in the fire, disposes other bodies to be reduced into a subtle scoria for the same attenuation.

SCORPION, *Scorpio*, in natural history, an insect frequently found in the hot countries. The opinions of authors are very different as to the sting of this creature, some asserting that there is an opening in it, through which a poisonous liquor is thrown into the wound made by it, as is the case in the tooth of the viper, &c. and others affirming that there is no such opening. Galen affirms that there is none, but most of the writers of the middle ages assert that there is. But the whole is set in the clearest light by Signior Redi, who took the pains of examining microscopically the stings of the scorpions brought alive from Tunis, Egypt, and Italy. These he nicely examined by the best glasses in the museum of the great duke of Tuscany, and could find no aperture: but, not satisfied with this, he pressed the stings to try if he could make any liquor flow out of them; they were, however, so hard and horny, that squeezing could have no effect on them; and, finally, he caused a scorpion to strike upon a plate of iron, but no liquid was found thereon; so that he began to conclude Galen's opinion right, when he accidentally discovered an exceedingly small drop of white liquor upon the sting, and this he afterwards found in all the trials he made with several scorpions. And Mr. Lewenhoeck discovered an opening on each side of the sting of this creature, for the emission of the poison, which he supposes is not discharged, till the sting is buried in the wound. *Baker's Microscope*.

Mr. de Maupertuis, having caused scorpions to bite several animals, of which very few died, or suffered any more than the pain of the sting, is of opinion, that oil of scorpions, and other vulgar antidotes to the poison of these animals, have rather got their reputation from the innocence of the sting of these creatures, than from any considerable virtue in the medicines. *Mem. de l'Acad. Scienc.* 1731.

Water SCORPION, *Scorpio Palustris*, a name given to a very remarkable species of water insect. It is a very thin and light little creature, yet is but a very slow mover. Its head is very small, and is hard to the touch, and of a paler brown than the rest of the body; and this is terminated by a very fine and sharp proboscis, of the same colour and texture. The eyes are small, but prominent, and very hard and black. The shoulders are broad and flat, they are of the same colour with the head, and are wrinkled on the surface. The triangular spot between the wings

is black and shining, the body is of a bright red lead colour on the back, and of a faint dusky brown on the belly, and is composed of six joints, covered with a sort of scales. The outer wings are very hard and firm, and lie very far over one another; they are opaque, and of a dark muddy brown, without any variations: the inner wings are of a dusky white veined with a red-lead colour. The two fore-legs are broader and thicker than the rest, and end in short blunt claws; these the creature never walks with, but always uses them as arms: the hinder pair are the longest, and both they and the middle ones end in a sharp claw; they are all of a pale brown; and somewhat transparent. The tail is long and straight; it is composed of two slender bristles, of a pale brown; the creature scarce ever separates these. It lives among the weeds in clear standing waters, and is continually watching for its prey. It feeds on other insects, and is particularly fond of the cicada aquatica, or worm of the great libella. It seizes its prey with the fore-legs, and holds it fast in them, while the proboscis pierces into the body, and sucks the juices.

SCORPION, *Scorpio*, in astronomy, the eighth sign of the zodiac, denoted by the character m . See the articles SIGN and ZODIAC.

The stars in the constellation Scorpio, in Ptolemy's catalogue, are twenty: in Tycho's ten: and in Mr. Flamsteed's forty-nine.

SCORPION, in the antient art of war, an engine chiefly used in the defence of the walls of fortified places, by throwing arrows, fire-balls, or great stones.

SCORZONERA, VIPER'S-GRASS, in botany, a genus of plants, with a compound imbricated flower, made up of a great many monopetalous, ligulated, and quinque-dentated small ones: the stamina are five very short capillary filaments: there is no pericarpium, except the imbricated cup, which becomes connivent, and contains a single oblong and striated seed after each lesser flower: the seeds are crowned with a plumose down.

The roots of this plant abound with a milky juice, of a bitterish subacid taste; and hence may be of some service for strengthening the tone of the viscera, and promoting the fluid secretions. They were formerly celebrated as alexipharmics, and for expelling the measles and small-pox; but have, of late, almost lost their character in these intentions.

SCOTLAND, exclusive of the islands, is situated between 1° and 6° west long. and between $54^{\circ} 30'$ and $58^{\circ} 30'$ north lat. being about three hundred miles long, from north to south, and from fifty to one hundred and fifty miles broad, from east to west.

Since the union with England, Scotland is divided into thirty-three shires, or counties, which all together send only thirty knights to parliament, by reason the shires of Bute and Cathness choose only alternately, or every other parliament in their turns; as do those of Cromartie and Nairn, Clackmannan and Kinross.

The royal boroughs of Scotland are sixty-five, but so classed as to send only fifteen burgesses to parliament.

New SCOTLAND, *Nova Scotia*, one of the British colonies in North America, is situated between 62° and 72° west long. and between 43° and 51° north latitude, being bounded by the river of St. Laurence on the north and north-west; by the bay of St. Laurence, and the Atlantic Ocean on the east; by the same ocean and New England on the south; and by Canada on the west.

SCRAPING, in naval affairs, the act of shaving or drawing off with scrapers the former crust of turpentine, tar, rosin, or such like materials with which a ship's-side had been covered, to protect the planks from the effects of the sun and wind. This is generally performed when the ship is to be new painted and cleansed, as at the fitting out for a voyage or expedition, at which time the bottom is also cleaned and covered a-new with a coat of sulphur, tallow, &c. See the article BREAMING.

SCREW, or SCRUE, *Cocblea*, one of the five mechanical powers. A screw is a cylinder cut into several concave surfaces, or rather a channel or groove made in a cylinder, by carrying on two spiral planes the whole length of the screw, in such a manner, that they may be always equally inclined to the axis of the cylinder in

their whole progress, and also always inclined to the base of it in the same angle.

The screw may also be considered as a wedge carried round a cylinder, which in that case is called the arbor of the screw; the wedge, so carried on, making what is called the thread of the screw, as may be seen in plate CXIII. *fig. 1, 2, 3, 4, and 5*; the arbor of the screw being *A B* in *fig. 1*, and *a c b d* in *fig. 2*, as if the cylinder *A C B D* was inscribed within the screw. Here, we may see the manner how a screw is made; for if it be cut out of the cylinder *P H I Q*, then *H K L M N O P* is a spiral line going about the cylinder, making the prominent part to be left of the said cylinder, and *b k l m n o*, the line marking the depth to which the screw is to be cut, supposing the same line to go round the inner cylinder or arbor *A B C D*, though not expressed here, to avoid confusion; and then *b L l N n*, &c. will represent the prominent part or thread of the screw. Now, if instead of cutting the hollows *H b L*, *L l N*, *N n P*, &c. into the cylinder *P H I Q*, a continued wedge be fixed to a smaller cylinder, as *A C B D*, or rather *a c b d*, the same kind of screw will be made, and *a b c d* will be the arbor of that screw. Sometimes the most prominent part of the thread, as *L N*, &c. is not sharp but flat, and then the thread is called a square thread, as in *fig. 5*, which represents the section of such a screw. This sort of thread is not used in wood, but in iron, and in other metals; it is of good service, being commonly more durable, and raising the weight with more ease than the sharp thread.

Force of the SCREW. To make an estimate of the force of the screw, which may be compared either to an inclined plane, or to a wedge, according as its arbor does or does not advance in a progressive motion whilst it turns round its axis to raise or stop a weight, or to press bodies together, which are the several uses of a screw, let us take a flexible wedge, as, for example, one of paper, and coil it round a cylinder, *fig. 1*. as is represented in the figure, where *A B* is the arbor, *C I D* one thread or helix, *D H E* another, and *E T G* part of the wedge left to shew the proportion between the power that turns the screw and the weight *W*.

If the weight is pushed up the wedge (or, which is the same thing, raised perpendicularly by the wedge slipping under it) from *F* to *H* in the direction *W w*, then will *H G* be the velocity of the weight, and *G T* the velocity of the power, which is the case of the inclined plane becoming a wedge; and this will be the analogy for the screw thus acting.

As a circle whose diameter is *H b*: to *H I* the distance of two threads :: (or as the base *F G*: to the perpendicular *H G*:) so is the weight: to the power applied to the arbor at *A*, to raise a weight up the thread *H D I C*.

N. B. We suppose the diameter of the arbor at *A* and of the screw at *H* nearly equal.

This is the case of *fig. 4*. where the moveable plank *D K* is carried down, by turning round the heads *G G* of the screws *A B* and *C D*, in order to press strongly the bodies placed between the planks *D K* and *M L*, whilst the piece *H I*, fixed on the upper plank, is either guided through an hole, or, being only looked at, serves to shew whether the plank *K D* be brought down horizontally, as the screws are turned. When long levers are thrust into the square holes at the heads of the screws, the force of the screw is much increased, and then the weight will be to the power :: as the circumference of the circle described by that part of the lever to which the hand is applied: to the distance between two threads. Wherefore, as the circumference of the circle is to the distance of two thirds of an endless screw :: so is the resistance of the teeth of the wheel: to the power applied to the handle.

Archimedes SCREW, in hydraulics, a kind of spiral pump, for raising water, so called from its inventor Archimedes.

It consists of a long cylinder, with a hollow pipe, tube, or groove coiled round it, as represented in plate CXIII. *fig. 7*, where *A B* represents the cylinder, and *C D* the tube open at each end. It is placed in an oblique position to the horizon, with the lower end in the water to be

pumped away, the other end being supported on the lower part of the winch *I K*, by which the screw and cylinder are turned round.

As soon as the screw is immersed in the water, it immediately rises therein by the orifice *C* to the level of the surface of the water *E F*; and if the point of the helix or spiral, which in the beginning of the motion is coincident with the surface of the water, happens not to be on the lower side of the cylinder, the water will, upon the motion of the screw, move on in the spiral, till it comes to the point which is on the other side, and coincident with the surface of the water: when it is arrived at that point, which suppose at *O*, it cannot afterwards possess any other part of the spiral than that which is upon the lowest part of the cylinder; for it cannot move from *O* towards *H* or *G*, because they are situated higher above the horizon: and since this will constantly be the case; after the water in the spiral has attained the point *O*, it is plain that it must always be on the under side of the cylinder.

But because the cylinder is in motion, every part of the spiral screw, from *O* to *D*, will, by degrees, succeed to the said under part of the cylinder; the water, therefore, in the spiral, must succeed to every part thereof, from *O* to *D*, as it comes on the lower side; that is, it must ascend on the lower part of the cylinder through all the length of the pipe, till it comes to the orifice *D*, where it will run out, as having nothing farther to support it. Hence it appears how much those gentlemen are mistaken who, affecting the wonderful, say, 'That the water ascends by descending;' whereas, if they would have made the most of the wonder, they might have truly said, 'That the water ascends because it cannot ascend,' i. e. that it ascends one way, because it cannot ascend another; but then the wonder is lost.

Endless or Perpetual SCREW, one so fitted in a compound machine, as to turn a dented wheel; so called, because it may be turned for ever without coming to an end; plate CXIII. *fig. 6*.

If, in the endless, or perpetual-screw, *A B*, whose threads take the teeth of the wheel *C D*, you take the distance of two threads, according to the length of the axis *A B*; or the distance of two teeth in the wheel *C D*, in the direction of the circumference; and if a weight, *W*, act at the circumference of the wheel: then if the power *D* be to the weight *W*, as that distance of the teeth or threads, to the length described by the power *P* in one revolution, the power and weight will be in æquilibrium; because in one revolution of *P*, the wheel *D C*, with the weight *W*, has moved only the distance of one tooth.

SCRIBE, an officer among the Jews whose business was to write; of which there were three kinds: the first and principal of which were the scribes of the law, whose office was to write and interpret scripture; these were in great credit and esteem among the Jews, and had even the precedence of the priests and sacrificers, and their decisions were received with almost the same respect as the law of God itself: the second kind, properly called scribes of the people, were a sort of magistrates; and the third were public notaries, or secretaries of the council; which were the least considerable.

The scribes, among the Romans, wrote out decrees, or acts, and made out authentic copies of them.

SCRIBING, in joinery, &c. is a term used when one side of a piece of stuff is to be fitted to another that is irregular. In order to make these join close all the way they scribe it; that is, they lay the piece to be scribed close to the other they intend to scribe it to, and opening their compasses to the widest distance these two pieces stand from each other, they bear the point of one of the legs against the side they intend to scribe to, and with the other point draw a line on the stuff to be scribed. Thus they form a line on the irregular piece parallel to the edge of the regular one; and if the stuff be cut exactly to the line, when these pieces are put together they will seem a joint.

SCRIPTURE, an appellation given, by way of eminence, to the sacred and inspired writings of the Bible. See **BIBLE**, **CANONICAL**, &c.

SCROPHULA, in medicine, the king's-evil.

The word is Latin, being a diminutive of *scropha*, a swine; because that animal is said to be subject to such a kind of disorder.

The cure of this disease is to be attempted by bleeding, purging, and such medicines as are most proper for correcting the viscidities, saltiness, and acrimony of the humours. The best cathartic is dulcified mercury six times sublimed, which should be joined with rhubarb for children; but to adults it may be given alone, with a gentle purging draught some hours after it. The next to this in virtue is jalap. And our purging waters are also useful, as they scour the glands, and open the body at the same time. In fine, a pill composed of mercury six times sublimed, and precipitated sulphur of antimony, each one grain: of aloes three or four grains made up with the syrup of balsam, and taken every night, will be found serviceable, not only in this disease, but in others arising from viscid humours.

The medicines which correct this pravity of the blood and humours, are, for the most part, of the diuretic kind, such as burnt sponge, the diuretic salt, and vitriolated tartar; which are the more proper, because they are somewhat laxative. To these may be added the less compound lime-water.

For my part, I have very often experienced the good effects of the following powder, taken twice a day, with three or four glasses of the aforesaid water. Take of burnt sponge one scruple, of purified nitre, coralline, and white sugar, each ten grains; mix these together. *Mead.*

SCROTUM, or **SCORTUM**, in anatomy, the cutaneous covering of the testes outwardly. It is a bag common to both, formed by a continuation of the skin of the neighbouring parts, and commonly very uneven, having a great number of rugæ on its outer surface. Interiorly it is fleshy, and forms a muscular capsula for each testicle called dartos.

The exterior or cutaneous portion of the scrotum is nearly of the same structure with the skin in general, of which it is a continuation, only it is something finer; and it is likewise plentifully stored with sebaceous glands and bulbs, or roots of hairs.

Though it is a common covering for both testicles, it is, nevertheless, distinguished into two lateral parts by a superficial and uneven prominent line, which appears like a kind of suture, and from thence has been termed raphe.

This line is a continuation of that which divides in the same manner the cutaneous covering of the penis; and it is continued through the peritonæum, which it divides, likewise, all the way to the anus. It is only superficial, and does not appear on the inside of the skin.

The inner surface of the cutaneous bag is lined by a very thin cellular membrane; through which the bulbs and glands appear very distinctly, when we view its inside. The rugæ of the scrotum are, in the natural state, commonly a mark of health, and then its size is not very large. It increases in size, principally, according to its length, and then the rugæ disappear more or less, according to the degrees of the preternatural state or indisposition. *Winslow's Anat.*

SCROWLS, or **SCROLLS**, in architecture. See **VOLUTES**.

SCRUPLE, a weight, containing twenty grains, or the third part of a dram. Among goldsmiths it is twenty-four grains.

SCRUPLES Eclipsed, in astronomy, that part of the moon's diameter which enters the shadow, expressed in the same measure wherein the apparent diameter of the moon is expressed.

SCRUTINY, a strict examination of the several votes hastily taken at an election, in order to discover any irregularities committed therein by unqualified voters, &c.

SCUDDING, in navigation, the act of flying before the wind in a great storm.

It is usual to scud under the fore-sail or fore-top sail, to guide the fore-part of the ship, and prevent her from broaching to; an incident of the most dangerous consequence, and to which she is frequently exposed in this

situation. However, when the storm is so violent as not to permit her to carry these sails, she may carry a part of the fore-sail; that is to say, the middle of it may be kept fast to the yard, whilst the two extremities, or yard-arms are loosed and extended, and this is called scudding under her goose-wings. If there should be too much wind for this, she must go without any sail, which is termed scudding under bare poles.

Scudding is rarely practised, but when the state of the ship renders it absolutely necessary on account of a leak or strain, or some other disaster; unless, indeed, when the wind which obliges her to scud happens to blow directly on the line of her course.

SCULPTURE, an art, which, by the means of a design or plan, and of solid matter, imitates the palpable objects of nature. Its matter is wood, stone, marble, ivory; different matters, as gold, silver, copper; precious stones, as agate and the like. This art includes, also, casting or founding, which is subdivided into the art of making figures of wax, and that of casting them in all sorts of metals. By sculpture, we understand here all those different species.

The sculptors and painters have often had great disputes amongst themselves upon the pre-eminence of their several professions; the first founding the preference upon the duration of their works, and the latter opposing them with the effects of the mixture and vivacity of colours. But, without entering into a question not easy to decide, sculpture and painting may be considered as two sisters that have but one origin, and whose advantages ought to be common; we might almost say, as the same art, of which design is the soul and rule, but which work in a different manner, and upon different materials.

It is difficult, and little important, to trace through the obscurity of remote ages, the first inventors of sculpture. Its origin may be dated with that of the world, and we may say that God was the first statuary, when, having created all beings, he seemed to redouble his attention in forming the body of man, for the beauty and perfection of which, he seems to have wrought with a kind of satisfaction and complacency.

The first sculptors made their works of earth, whether they were statues, or moulds and models. This made the statuary Praxiteles say, that the works which were either cast, or cut with a chissel or graver, owed their being to the making figures of earth, called plastice. It is said, that Demaratus, the father of Tarquinius Priscus, who took refuge from Corinth in Etruria, brought thither abundance of workmen with him, who excelled in that art, and introduced the taste for it there, which afterwards communicated itself to the rest of Italy. The statues erected in that country to the gods, were at first only of earth; to which for their whole ornament, was added a red colour. We ought not to be ashamed of the men, says Pliny, who adored such gods. They set no value upon gold and silver, either themselves or their deities.

We find that the ancients made statues of almost all sorts of wood. There was an image of Apollo at Sicyone made of box. At Ephesus, according to some writers, that of Diana was of cedar, as well as the roof of the temple. The lemon-tree, the cypress, the palm, the olive, the ebony, the vine, in a word, all trees not subject to rot, or to be worm-eaten, were used for statues.

Marble soon became the most usual and most esteemed material for works of sculpture. It is believed that Dipænes and Scyllis, both of Crete, were the first that used it at Sicyone, which was long, in a manner, the center and school of arts: they lived about the 50th Olympiad, a little before Cyrus reigned in Persia.

Bupalus and Anthernus, two brothers, made themselves famous for the art of carving marble in the time of Hipponax, that is, in the 60th Olympiad. That poet having a very ugly face, they made his portrait, in order to expose it to the laughter of spectators. Hipponax conceived a more than poetic fury against them, and made such virulent verses upon them, that, according to some, they hanged themselves through grief and shame. But this fact cannot be true, because there were works of their making after that time.

At

At first the artists used only white marble, brought from the isle of Paros. It was reported, that in cutting these blocks of marble, they sometimes found natural figures of a Silenus, a god Pan, a whale, and other fishes. Jasper, and spotted marble, became afterwards the fashion. It was brought principally from the quarries of Chio: and soon was commonly found in almost all countries.

It is believed that the manner of cutting large blocks of marble into many thin pieces, to cover the walls of houses, was invented in Cairo. The palace of king Mausolus, at Halicarnassus, is the most ancient house that had these incrustations of marble, which were one of its greatest ornaments.

The use of ivory, in works of sculpture, was known from the earliest ages of Greece. Homer speaks of them, though he never mentions elephants.

The art of casting gold and silver is of the greatest antiquity, and cannot be traced to its origin. The gods of Laban, which Rachel stole, seem to have been of this kind. The jewels offered to Rebecca were of cast gold. Before the Israelites left Egypt, they had seen cast statues, which they imitated in casting the golden calf, as they did, afterwards, in the brazen serpent. From that time all the nations of the East cast their gods, *deos conflantes*, and God forbid his people to imitate them upon pain of death. In the building of the Tabernacle, the workmen did not invent the art of founding. God, only, directed their taste. It is said that Solomon caused the figures used in the Temple, and elsewhere, to be cast near Jericho, because it was a clayey soil, which shews that they had even then the same manner of founding great masses as we have.

It were to be wished that the Greek and Roman authors had informed us in what manner the ancients cast their metals, in making figures. We find, by what Pliny writes on that head, that they sometimes made use of stone moulds. Vitruvius speaks of a kind of stones found about the lake Volsenus, and in other parts of Italy, which would bear the force of fire without breaking, and of which moulds were made for casting several sorts of works. The ancients had the art of mingling different metals in the mould, to express different passions and sentiments by the diversity of colours.

There are several ways of carving metals and precious stones: for in both the one and the other they work in relief, and in hollow, which is called engraving. The ancients excelled in both ways. The basso relievo's which we have of theirs, are, by good judges, infinitely esteemed: and as to engraved stones, as the fine agates and crystals, of which there are abundance in the king of France's cabinet, it is generally said, that there is nothing so exquisite as those remains of the ancient masters.

Though they engraved upon almost all kinds of precious stones, the most finished figures which we have of theirs are cut upon onyxes, a kind of agate not transparent; or on cornelians, which they found more fit for engraving than any other stones, being more firm and even, and cut more neatly; and, also, because there are different colours that run one above another in the onyx, by the means of which, in relievo, the bottom continues of one colour, and the figures of another. To engrave upon gems and crystals, they used, as now, the point of a diamond.

The ancients highly extolled the gem in the ring of Polycrates, tyrant of Samos, which he threw into the sea, and was brought back to him by a very extraordinary accident: in Pliny's time it was pretended to be at Rome. It was, according to some, a sardonix, to others an emerald. That of Pyrrhus was no less esteemed; upon which might be seen Apollo with his harp and the nine muses, each with their peculiar symbol: and all this not the effect of art but of nature.

The art of sculpture was principally employed upon cups used at feasts: these pieces were very rich and curious, as well as of the most costly materials.

One of the greatest advantages the art of making portraits ever received for the eternizing its works, is that of engraving upon wood and copper plates, by the means of which a number of prints are taken off, that multiply a

design almost to infinity, and convey the artist's thoughts into the different parts, which before could only be known from the single piece of his own work. There is reason to wonder, that the ancients, who engraved so many excellent things upon hard stones and crystals, did not discover so fine a secret, which, indeed, did not appear till after printing, and was, no doubt, an effect and imitation of it; for the impression of figures and cuts did not begin to be used till the end of the fourteenth century. The world is indebted for the invention of them to a goldsmith, that worked at Florence. See ENGRAVING.

SCUPPERS, in ship-building, small channels cut through the ship's-side, with a gradual slope from the decks. They are used to carry off the water which may lie on the deck; for which purpose there is frequently a leathern pipe nailed on the out-side all round the scupper-hole, to carry the water down without staining or dirtying the vessel's side. These are termed scupper-holes.

SCURRA, in ornithology, the name by which the ancients called the jackdaw.

SCURVY, *Scorbutus*, a name given by medicinal writers to a disease so various and different in appearance, that it does not seem to be one and the same distemper. In the northern countries it has always been common, and the nearer they are to the sea, the more severe it proves: Accordingly the Danes, Norwegians, and other inhabitants of the coasts of the Baltic, are vastly afflicted with it; nor do the Germans, Dutch, or our own countrymen, escape its fury.

It begins by foul ulcers in the mouth and legs, whence it is called stomacace and sceletyrbe by Pliny, who imputes it to the bad qualities of water, and says, that the herba Britannica, which is believed to be the hydrolapathum nigrum of Muntingius, or great water-dock, was found to be its cure. But the disease was known long before Pliny's time: for Hippocrates describes it by the name of *σπλην μέγας*, or great spleen; and says, likewise, that it arises from drinking cold, crude, turbid waters.

I remember to have formerly seen, in St. Thomas's hospital, an instance of this case in a country fellow of the isle of Sheppy; which place is notorious for moist thick air, and unwholesome water. When the Roman army, under the command of Claudius, landed in Britain, and the troops were stationed in the abovementioned island and places adjacent, they there contracted this disease; and it is not improbable that some of the natives shewed them the herb which Pliny says was of service to them, and that the Romans gave it the name of herba Britannica, from the country; for it is well known that that emperor embarked his army for that expedition at Boulogne, which is directly opposite to Kent. Strabo relates a similar story of the Roman army, which Augustus sent into Arabia under the command of Aelius Gallus: for, he says, that while they were at Albus Pagus, the soldiers were seized with disorders of the mouth and legs, called stomacace and sceletyrbe, which are an endemic in that country, and are a sort of relaxation proceeding from the waters and vegetables. Now to me it is very plain that the unwholesome sea air, bad diet, and worse water, rendered that climate subject to those disorders; for Ptolemy, in his Geography, places Albus Pagus on the coast of the Sinus Arabicus, or Red Sea. But to return from this digression: The poor patient had an irregular intermitting fever, with a bad habit of body; and, likewise, an ill-natured ulcer in each of his legs. By the use of medicines proper for the scurvy, I mean biters and diuretics, he seemed to grow better, for one of the ulcers was, by chirurgical applications, entirely healed; but while the other was under cure, a gangrene seized the part unexpectedly; which, being scarified, in order to check its progress, the patient died suddenly. Upon opening the abdomen, we were struck with amazement at the monstrous size of the spleen; for it weighed five pounds and a quarter, whereas the liver weighed but four and a quarter. But its bulk seemed to be its only defect: for it retained its natural shape and colour, and had not the least scirrhoty or other hardness: and its inside was, as usual, of a dark livid hue, with lax fibres, and deep-coloured blood. From the above-mentioned

ulcers the breath becomes offensive, the gums are corrupted and turn livid, and sometimes blackish, and upon pressing then lightly with the finger, they emit a dusky gore: besides, they are so lax and flabby, that they quit their hold of the teeth; and these are sometimes so loose, that they may all be pulled out with great ease. In the mean time greenish and livid spots, like the remains of ecchymoses, appear on various parts of the body, as on the arms, buttocks, thighs, legs, and frequently all over the skin, so as to make it have the appearance of a jaundice. The patient is also tortured with severe gripings. And from this symptom it is that the disease has obtained its name, being derived from the Saxon word *scherbock*, or *scherbuck*, which signifies tearings of the belly.

Besides unwholesome waters, medical writers attribute the disease partly to salted provisions and pulse; which, as they are of different concoction, furnish the body with gross and improper nutriment. But they seem not to have sufficiently attended to a more universal cause, I mean, bad air, which, taken into the lungs, is very prejudicial. This is particularly manifest in long voyages, in which the sailors are most severely afflicted with this distemper, of which we have a remarkable and moving account in the history of lord Anson's expedition to the South Seas, in which that great commander lost near one third part of his men by this cruel enemy; and the calamity rose to such a high pitch, that the callus of broken bones, which had been completely formed for a long time, was found dissolved, and the fracture seemed as if it had never been consolidated. Wherefore, in these cases, there must certainly be a high degree of putrefaction; and the blood becomes so foul a mixture, that whensoever it be drawn, it has nothing of its natural red colour, but resembles a dark muddy puddle. Now, as to the manner in which the causes abovementioned corrupt and putrify the humours, it will be easily found by those who are well acquainted with the proportion and laws of motion in the animal machine.

With regard to the cure, it is much easier to prevent the scurvy than to remove it; for, when it has once taken root in the body, it is very difficult to drive it out by medicines. Now, its best remedy is good wholesome air and proper diet; wherefore, as soon as a person is taken ill, if he be at sea, he ought to alter his situation as soon as possible and get ashore, to breathe the land air; but, if on land, he should go into the country for the benefit of purer open air. And in both cases, what flesh he eats should be fresh and tender; but the greatest part of his food ought to be vegetables, both such as abound in volatile salt, as scurvy-grass, cresses, brook-lime, and the like; and those which are of a cooling nature, as sorrel, endive, lettuce, purslain, and others of this kind. And it will often be beneficial to eat all these, or some of each sort, promiscuously together. But the greatest service may be expected from subacid fruits, as lemons, oranges, and pomegranates, eaten frequently upon account of their cooling and subastringent quality. *Mead's Monita & Precepta.*

SCURVY-GRASS, *cochlearia*, in botany. See the article COCHLEARIA.

SCUTAGE was antiently a tax imposed on such as held lands, &c. by knight's service, towards furnishing the king's army: hence *scutagio habendo* was a writ that lay for the king, or other lord, against tenants holding by knight's service, to serve in person, or send a sufficient man in their room, or pay a certain sum, &c.

SCUTIFORME Os, in anatomy, the chief bone of the knee, called also *patella*, *mola*, &c. See the article PATELLA.

SCUTIFORMIS CARTILAGO, in anatomy, one of the cartilages of the larynx, the broadest and biggest of them all, called also *thyroides*. See LARYNX.

This cartilage is of a quadrangular figure, and stands in the anterior part, where the *pomum Adami* makes its prominence, whence it is sometimes called the anterior cartilage. It is gibbous without-side, and hollow within; sometimes double, chiefly in women, in whom it does not advance so far forward as in men.

SCUTTLE, in ship-building, a sort of small square

hole, cut through the decks or hatch-coverings of a ship to pass up and down through. See the article HATCH-WAY.

SCYTALA, in mechanics, a term used by some writers, for a kind of radius, or spoke, standing out from the axis of a machine, as an handle or lever to turn it round and work it by.

SCYTALA LACONICA, a stratagem or device of the Lacedemonians, for the secret writing of letters to their correspondents, so that if they should chance to be intercepted, nobody might be able to read them. To this end they had two wooden rollers or cylinders, perfectly alike and equal, one whereof was kept in the city; and another by the person to whom the letter was directed. For the letter, a skin of a very thin parchment was wrapped round the roller, and thereon was the matter written; which done, it was taken off, and sent away to the party, who upon putting it in the same manner upon his roller, found the lines and words in the very same disposition as when they were first written.

SEA, *Mare*, in geography, is frequently used to signify that vast body of water encompassing the whole earth, more properly called ocean.

Sea is more properly used for a particular part or division of the ocean; denominated from the country it washes, or other circumstances. As the Irish Sea, Mediterranean Sea, Baltic Sea, North Sea, Red Sea, &c.

The sea differs in saltness in different parts; it is in general observed, that in the hottest climates the water is saltest.

When salt water freezes, it hath been thought to let fall all its salt; the ice of sea water, and the water melted from it, tasting fresh, and being good for boiling meat and pease in. Captain Middleton, being in Hudson's Straights in July 1738, took ice from under the surface of the sea, which he melted till he got forty quarts of water; these he evaporated to dryness, and out of that quantity had only six ounces of salt, or about $\frac{1}{11}$. *Phil. Transf.* N^o. 461.

General Motion of the SEA. Mr. Daffie of Paris, in a work published about sixty years ago, has been at great pains to prove that the sea has a general motion, independent of winds and tides, and of more consequence in navigation than is usually supposed. He affirms that this motion is from east to west, inclining towards the north, when the sun has passed the equinoctial northward, and that during the time the sun is in the northern signs; but the contrary way, after the sun has passed the said equinoctial southward; adding, that, when this general motion is changed, the diurnal flux is changed also: whence it happens, that in several places the tides come in during one part of the year, and go out during the other; as on the coasts of Norway, in the Indies, at Goa, Cochinchina, &c. where, while the sun is in the summer signs, the sea runs to the shore; when in the winter signs, from it. On the most southern coasts of Tonquin and China, for the six summer months, the diurnal course runs from the north with the ocean; but, the sun having repassed the line toward the south, the course declines also southward. *Philos. Transact.* N^o. 135.

Basin of the SEA, *Fundus Maris*, a term used by geographers, and other writers, to express the bottom of the sea in general.

Our honourable Mr. Boyle is the first who has written any thing on that part of the globe, and he has given us a treatise expressly upon it; but this only gives an account of its irregularities, and unequal depths, and is founded on the observations communicated to him by mariners, and people of too little curiosity to be depended upon for great discoveries.

The ingenious Count Marfigli has, since his time, given us a much fuller account of this part of the globe, in a great part from his own experiments in many places, particularly along the coasts of Provence and Languedoc.

The entire basin of the sea is of such immense extent, and covered in many places with such an unfathomable depth of water, that it is not to be expected that it can be traced in every part; but as the whole may be guessed at, from some part of it, and as its general figure is of no consequence in a search of this kind, the observations of

this curious author are of great value, in forming a judgment of the whole.

The materials which compose the bottom of the sea, may very rationally be supposed, in some degree, to influence the taste of its waters: and Marfigli has made many experiments to prove, that fossil coal, and other bituminous substances, which are found in plenty at the bottom of the sea, may communicate in great part its bitterness to it. We are not, however, to judge hastily, that there are not so many beds of these at the bottom of the sea, as would be necessary for such a purpose, or to judge too hastily against the existence of any other substances there, because we do not find proofs of them by the plummet, which in sounding brings up other substances, and not these; for the true bottom of the sea is very often covered and obscured from us by another accidental bottom, formed of various substances mingled together, and often covering it to a considerable depth.

The entire gulf of Lyons, situated between Cape Quiez in Roussillon, and Cape Croisit in Provence, forms a bank above the surface of the water at the shore, of the exact and perfect figure of an arch; and within this there is formed another such arch, making the bottom of the sea in that place for a very great way from shore, which is of different depths in various places, but usually between sixty and seventy fathoms.

It is a general rule among sailors, and is found to hold true in a great many instances, that the more the shores of any place are steep and high, forming perpendicular cliffs, the more deep the sea is below; and that, on the contrary, level shores denote shallow seas. Thus the deepest part of the Mediterranean is generally allowed to be under the height of Malta. The observation of the strata of earth, and other fossils, on and near the shores, may serve to form a very good judgment, as to the materials which are found in its bottom. The veins of salt and of bitumen doubtless run on the same, and in the same order in which we see them at land; and the strata of rocks, that serve to support the earth of hills and elevated places on shore, serve also, in the same continued chain, to support the immense quantity of water in the basin of the sea. It is probable also that the veins of metals, and of other mineral substances, which are found in the neighbouring earth, are in the same manner continued into the depths of the sea. The particles of metals, in this case, are probably carried off into deep water, and sunk among the softer matter of the bottom; but some of the lighter minerals seem to have given colour to those beautiful crusts, which are found upon many sea plants, and which lose their lustre in the drying. The subterranean rivers, and currents of water, make great changes in what would be the natural surface of the bottom of the sea, where they arise, each having a peculiar basin of its own. We are informed by numerous instances of subterranean currents, and, as we see them break out in rivers on the surface of the earth in some parts, so in others we may be well assured that they break up the bottom of the sea, and empty their fresh waters into the salt mass.

In this case, the rushing up continually of such a body of water makes a roundish cavity, and its running some one way lengthens and carries on that cavity, till by degrees it is lost, as the fresh water by degrees becomes blended with the salt. Thus every river, that arises in the bottom of the sea, alters the form of its surface, and makes a basin for itself, in which it runs a considerable way. Many seas near the shore, and when the water is tolerably clear, shew the traces of these currents to the naked eye from the surface, and the water taken up from them is found more or less fresh. The coral fisheries have given us occasion to observe, that there are many, and those very large, caverns or hollows in the bottom of the sea, especially when it is rocky; and that the like caverns are sometimes found in the perpendicular rocks, which form the steep sides of those fisheries. These caverns are often of great depths, as well as extent, and have sometimes wide mouths, equal to their largest diameter in any part, but sometimes they have only narrow entrances into large and spacious hollows. It is the common opinion of the people about the place, that these caverns are prepared by nature for the circu-

lating of the sea water; but that operation, however necessary, may be performed as well without, as with these caverns, and they seem in reality to be only accidental.

We daily meet with immense hollows and caverns, naturally made in rocky mountains; and as this part of the bottom of the sea is almost all rock, and its sides of the same nature, it is no wonder that the same accidents should happen, and like hollows be found, though with no particular intent of Providence in their use. Nay there is this farther reason to expect them in the rocks buried under the sea than in those in hills, that the latter are in a state of rest and quiet, whereas the former are in continual reach of water, which will insinuate itself into every crack or crevice nature has left in them, and may be easily supposed to have burrowed its way in a small hole made by nature, till it has formed of it a very large one.

It seems plain from the whole, that the basin of the sea was at the creation, or at its second formation after the universal deluge, covered with, or composed of the same substances, as the surface of the rest of the earth is, that is, of rocks, clay, and sand, and other such substances. The common observations of seamen seem indeed to make against this opinion, but they may be easily solved, so as not to overthrow it. The plummet which they let down in sounding, usually brings up with it a matter composed of mud, tartarous incrustations, or of dead weeds and broken shells, or numbers of various bodies of this kind, cemented together into a firm mass by some sparry or tartarous matter, deposited from among the water, and agglutinating them together: these form an artificial bottom, covering the natural one; but it is easy to see, that such a crust or coat as this must needs have been formed over the true bottom, in places where numbers of animals and vegetables are produced, and decay again, and where the waters being at rest have time to deposit their stony matter, in the same manner as the waters of several of our petrifying, or rather incrustating springs do. And that these decayed substances, and this stony matter, falling to the bottom together, and there lying undisturbed, must necessarily have formed just such a crust as is found; and the natural bottom of the sea, whether of stone, of sand, or of clay, must be covered by such accidental concretions, and that probably to such a depth, that it is not easy now to break through it. There are places however where, by some accidents, this sort of adventitious crust either has never been formed, or else has been removed. In these places we find the natural bottom, as described, that is, of the same nature with the strata in the body of the earth. The simile the Count Marfigli has made, between the basin of the sea and a cask of wine, is very expressive and just. When wine has been a long time kept in a cask, the whole internal surface of that cask is so covered and incrustated over with tartar, that it seems within to be really composed of it; yet, as we know that this cask is of wood, we are very certain that the true inner surface of it is of the same texture and nature with the tree from which it was cut, though we cannot get off the accidental surface formed by the liquor kept in it, and wholly covering it.

We very frequently meet with fine and pure sand at the bottom of the sea, and in these places are apt to believe that we certainly have the true and original bottom, but this is rather to be looked on as a probability than a certainty; and, where the sand is more than ordinarily fine, there is always reason to suspect that the course of some subterranean river has brought it there, by opening into the sea in this part; and that this is one of those particular basins, which these rivers form to themselves within the basin of the sea, and which continue only to a small distance from their source.

The bottom of the sea is covered with a variety of matters, such as could not be imagined by any but those who have examined into it, especially in deep water, where the surface only is disturbed by tide and storms, the lower part, and consequently its bed at the bottom, remaining for ages perhaps undisturbed. The soundings, when the plummet first touches ground on approaching the shores, gives some idea of this. The bottom of the plummet is hollowed, and in that hollow there is placed a lump of tallow; this, being at the bottom

tom of the lead, is what first touches ground, and the soft nature of this fat receives into it some part of those substances, which it meets with at the bottom: this matter, thus brought up, is sometimes pure sand, sometimes a sort of sand made of the fragments of shells, beat to a sort of powder; sometimes it is made of a like powder of the several sorts of corals, and sometimes it is composed of fragments of rocks: but besides these appearances, which are natural enough, and are what might very well be expected, it brings up substances which are of the most beautiful colours. Things of as fine a scarlet, vermilion, purple, &c. as the finest paint could make them, and as yellow as a solution of gamboge, are common; and sometimes, though not so frequently, the matter brought up is blue, green, or of a pure snowy whiteness. These coloured matters sometimes seem to have made up the whole bottom or mass of the surface, but more usually they have been formed upon other things, as upon the mud, or upon larger pieces of shells, corals, and the like, in the manner of tartarous crusts, and those in some degree resembling the crustaceous coats of some of the sea plants. The colours of these substances are not merely superficial and transient, but many of them are so real and permanent, that they may be received into white wax melted, and poured upon them, or kept in fusion about them; and, when thus examined, they seem as if a proper care might make them of great value, as paints of the finer kinds, where little is to be used.

The same coloured matters that thus coat the substances, found at the bottom of the sea in these places, are also sometimes found extended over the surface of sea plants of the harder kind, which grow in deep water. They are always, in this case, in a sort of liquid form, being lodged within, or embodied among a sort of jelly or glue of a transparent substance, which in these cases perfectly coats over the whole plant. In this state it gives the naturalist, who is present at the fishing up his treasures, a transient prospect of a very elegant kind; but this vanishes, while he admires it. A piece of coral, or other hard sea plant, thus coated over, appears, as it rises to the surface of the water, of a delicate green, blue, or purple; but, when taken above water, it is found that this fine colour is only in the coat of glue or jelly which covers the plant: as soon as this is wiped off, the colour is carried away with it, and the coral shews its own native tinge; and it is to no purpose to attempt the preserving it, by suffering this glue to dry upon the plant, for the colour flies away by degrees, as the moisture evaporates; and the coral or plant, whatever it be, is only so much the less beautiful, than it naturally would have been, as it is covered with a dry yellowish dirty-looking horny matter. These are beauties in the submarine plants, therefore, which can be only seen by those who venture out, in order to take them up.

The small quantities of these elegant colours, which we thus find spread over the surfaces of plants and other bodies, as we approach deep water, may give a rational idea of what we should find, were we able to examine the bottoms of the sea in its deep and unfathomable recesses. It is easy to conceive, that in these places we should find great quantities of the most beautiful substances. *Marfigli, Hist. Phys. de la Mer.*

SEA Breaches, a term used by the farmers to express the over-flowing of their low lands near the sea by the sea water.

Sea salt, moderately used, is a great improvement to all lands, but too much of it kills all sorts of vegetables, except such as nature has intended to live among it. The sea, breaking in upon lands thus, injures them greatly. The owner is to stop the breach by which it entered with all possible diligence, and then trenches and drains must be cut through all parts of the land, to carry the salt water into some one low place, from which it may be emptied by means of an engine; or, if it be small in quantity, it may be laded out by hand over the bank; or, if yet less, the sun and winds may dry it away: but, in either case, the place where it was suffered to rest must be covered with a large quantity of fresh earth, to take off from the too great saltiness of the other; and the whole land should be plowed for three or four years, to let in the rains and air to freshen it. *Mortimer's Husband.*

SEAL, *Sigillum*, a puncheon, or piece of metal, or other matter, usually either round or oval, whereon are engraven the arms, device, &c. of some prince, state, community, magistrate, or private person, often with a legend or subscription, the impression whereof, in wax, serves to make acts, instruments, &c. authentic.

Before the time of William the Conqueror, the makers of all deeds only subscribed their names, adding the sign of the cross, and a great number of witnesses; but that monarch, and the nobility, used seals with their arms on them, which example was afterwards followed by others. The colour of the wax wherewith this king's grants were sealed was usually green, to signify that the act continued fresh for ever, and of force.

A seal is absolutely necessary in respect of deeds, because the sealing of them makes persons parties thereto, and without being sealed, they are void in law. It is held, that if a seal be broken off, it will render the deed void, and that where several are bound in a bond, the pulling off the seal of one vacates it as to all the rest.

The king's great seal is that whereby all patents, commissions, warrants, &c. coming from the king are sealed. The keeping hereof is in the hands of the lord high-chancellor, who is hence denominated lord keeper. Indeed there is some difference between the lord chancellor and lord keeper, not in office, but in the manner of creation, the latter being made by the delivery of the great seal to him by the king, but the former having a patent. The king's privy seal is a seal that is usually first set to grants that are to pass the great seal. See the article **KEEPER**.

SEAL is also used for the wax or lead, and the impression thereon, affixed to the thing sealed.

SEALER, an officer in chancery, appointed by the lord chancellor or keeper of the great seal, to seal the writs and instruments there made in his presence.

SEALING, in architecture, the fixing a piece of wood or iron in a wall with plaster, mortar, cement, lead, and other solid binding. For staples, hinges, and joints, plaster is very proper.

SEALING-WAX. See the article **WAX**.

SEAM or **SEME** of *Corn*, is a measure of eight bushels.

SEAM of *Glass*, the quantity of 120 pounds, or 24 stones, each five pounds weight. The seam of wood is an horse load.

SEAMS, in ship-building, the interstices between the planks in a ship's decks, sides, or bottom: they are filled with a quantity of oakum, or old ropes untwisted and drawn asunder, after which they are covered with hot melted pitch, to prevent the entrance of the water. See **CAULKING**.

SEAR-CLOTH, or **CERE-CLOTH**, in surgery, a form of external remedy somewhat harder than an unguent, yet softer than an emplaster, though it is frequently used both for the one and the other. The sear-cloth is always supposed to have wax in its composition, which distinguishes and even denominates it. In effect, when a liniment or unguent has wax enough in it, it does not differ from a sear-cloth. Sear-cloths are a kind of substitutes to friction, and are sometimes used for other purposes: the best are compounded of resolvent drugs, as saffron, myrrh, and aloes, incorporated with wax and gums, as galbanum, gum ammoniac, and sagapenum, the whole tempered with wine.

SEASONS, in cosmography, certain portions or quarters of the year, distinguished by the signs which the earth then enters, or by the meridian altitudes of the sun, consequent on which are different temperatures of the air, different works in tillage, &c. The year is divided into four seasons, spring, summer, autumn, and winter. The beginnings and endings of each whereof, see under its proper article, **SPRING**, &c.

SEBUÆI, a sect among the ancient Samaritans; whom St. Epiphanius accuses of changing the time expressed in the law, for the celebration of the great annual feasts of the Jews. Serrarius conjectures, that they were thus called, from their celebrating the feast of the passover on the seventh month, called by the Hebrews *seba*, seventh.—Drusius rather takes them to have

been denominated from Sebaia, the leader of a sect among the Samaritans; as the followers of Dositheus were denominated Dositheï; which two sects some Jewish doctors suppose to have subsisted at the same time.—Scaliger derives the name from the Hebrew *seba*, week; as who should say, *Hebdomadites*, because of their celebrating every second day of the seven weeks, between Easter and Whitsuntide. Yet the same Scaliger, in his answer to Serrarius, gives a different explication.—In effect, all that has hitherto been advanced on the point, is mere conjecture.

SEBURAI, SEBURÆI, a name which the Jews give to such of their rabbins or doctors, as lived and taught some time after the finishing of the Talmud.

The word is derived from סבר, *sebar*, I think, whence סברא, *sebura*, opinion, sentiment; and thence סבוראי, *seburi*, or *seburai*, opinionative.

The reason of this appellation, say the rabbins, is, that the Talmud being finished, published, and received in all the schools and synagogues, these doctors had nothing to do, but dispute for, and against, the Talmud and its decisions. Others say, it was because their sentiments were not received as laws, or decisions, as those of the Mischnic and Gemaric doctors were; but were held as mere opinions. Others, as the author of *Scalscheleth Hakkabala*, or *Chain of Tradition*, tell us, that the persecution the Jews underwent in those times, not allowing them to teach quietly in their academies, they only proposed their opinions on the composition of the Mischna.

The first and chief of the Seburai was R. Josi, who began to teach in the year 787 of the æra of contracts; which, according to R. David Gautz, falls on the year of the world 4236; and who, according to R. Abraham, was 38 years president of the Jewish academy.

This æra of contracts is the same with that of the Seleucidæ, the 787th year whereof falls on the year of Christ 476, which, of consequence, is the æra of the origin of the Seburai; whose reign did not hold long: Buxtorf says, not above sixty years; but R. Abraham, and others, not fifty. The last of them was R. Simona. They were succeeded by the Gaons of Geonim.

SECALE, or SECALINA, RYE. See the article RYE.

SECANT, in geometry, is a line that cuts another, or divides it into two parts.

Thus the line A M (plate CXIII. fig. 8.) is a secant of the circle A E D, &c. as it cuts it in B.

It is demonstrated by geometers, 1. That if several secants M A, M N, M E, &c. be drawn from the same point M, that passing through the center M A is the greatest, and the rest are all so much the less as they are more remote from the center. On the contrary, the portions thereof without the circle M D, M O, M B, are so much the greater as they are farther from the center. 2. That if two secants, M A and M E, be drawn from the same point M, the secant M A will be to M E as M D to M B. See the article TANGENT.

In trigonometry, the secant denotes a right line drawn from the center of a circle, which cutting the circumference, proceeds till it meets with a tangent to the same circle: thus the line F C drawn from the center C till it meet the tangent E F, is called a secant; and particularly the secant of the arch A E, to which E F is a tangent. The secant of the arch A H, which is the complement of the former arch to a quadrant, is called the co-secant, or secant of the complement.

SECOND, in geometry, chronology, &c. the sixtieth part of a prime or minute, whether of a degree, or of an hour; it is denoted by two small accents, thus (").

SECOND, in music, one of the musical intervals; being only the difference between any sound, and the next nearest sound, whether above or below it.

As in the compass of a tone some reckon nine sensible sounds, and others ten, which form the intervals called commas; so there are eight kinds of seconds according to the former opinion, and nine according to the latter. However, in practice, they usually distinguish only four sorts. 1. That called a diminished second, containing four commas; being the difference, for instance, of

a natural *ut*, and an *ut* sharp. 2. That called a second minor, or imperfect second, containing five commas, viz. from *mi* to *fa*; or from *la* to B *mol*; or from *fa* sharp to *sol*. 3. A major second, called by the Italians a perfect second, containing nine commas. 4. A redundant second, composed of a whole tone, and a minor semi-tone.

SECONDARY, in general, something that acts as second, or in subordination to another.

Secondary circles of the sphere, are circles passing through the poles of some great circle: thus the meridians and hour-circles are secondaries to the equinoctial. There are also secondaries passing through the poles of the ecliptic, by means of which all stars are referred to the ecliptic. See the articles ECLIPTIC, LONGITUDE, SPHERE, &c.

SECRETARY, an officer who by his master's orders writes letters, dispatches, and other instruments, which he renders authentic by his signet. Of these there are several kinds; as, 1. Secretaries of state, who are officers that have under their management and direction the most important affairs of the kingdom, and are obliged constantly to attend on the king: they receive and dispatch whatever comes to their hands, either from the crown, the church, the army, private grants, pardons, dispensations, &c. as likewise petitions to the sovereign; which when read, are returned to them; all which they dispatch according to the king's direction. They have authority to commit persons for treason, and other offences against the state, as conservators of the peace at common law, or as justices of the peace throughout the kingdom. They are members of the privy-council, which is seldom or never held without one of them being present; and as to the business and correspondence in all parts of this kingdom, it is managed by either of the secretaries without any distinction; but with respect to foreign affairs, the business is divided into two provinces or departments, the southern and the northern, comprehending all the kingdoms and states that have any intercourse with Great Britain; each secretary receiving all letters and addresses from, and making all dispatches to, the several princes and states comprehended in his province: which division still subsists, notwithstanding the addition of a third secretary for Scotland. Ireland and the Plantations are under the direction of the elder secretary, who has the southern province, which also comprehends France, Italy, Switzerland, Spain, Portugal, and Turkey: the northern province includes the Low Countries, Germany, Denmark, Sweden, Poland, and Muscovy. Each of the secretaries have an apartment in all the royal houses, both for their own accommodation and their officers; they have also a table at the king's charge, or else board-wages. The two secretaries for South Britain, have each two under secretaries, and one chief clerk; and the secretary for North Britain has an under secretary, and one chief clerk, with an uncertain number of other clerks and translators, all wholly depending on them. To the secretaries of state belong the custody of that seal properly called the signet, and the direction of two other offices, one called the paper-office, and the other the signet-office.

2. Secretary of an embassy, a person attending an ambassador for writing dispatches relating to the negotiation. There is a great difference between the secretary of an embassy, and the ambassador's secretary; the last being a domestic or menial of the ambassador, and the first, a servant or minister of the prince.

3. The secretary of war, an officer of the war-office, who has two chief clerks under him, the last of which is the secretary's messenger. There are also secretaries in most of the other offices.

CRETION, *secretio*, the act whereby the several juices or humours of the animal body are separated from the blood by means of the glands.

It is a thing well known to philosophers, and particularly to chemists, that a piece of waste paper, which consists of a parcel of filaments connected together, being once soaked in oil or water, will not suffer any other liquor to pass through it, but such as it was saturated with before, stopping all others. It is also known that scraps of cloth or cotton imbued with oil or water, and

Fig. 11.

Fig. 12.

and dipped in a vessel, in which oil and water are mixed together, that which was saturated with water will suffer nothing to pass but water, and that which had the oil will let nothing pass but oil.

There are to be found in the secretory vessels of the glands a similar structure, an interwoven mass of filaments very like those of paper, cloth, or cotton, though disposed a little differently. This texture, once filled with a certain juice, will let none pass through of all the juices that come to the orifices of these vessels, but that with which they were already saturated.

This being so, the blood, which we ought to consider not as a homogeneous fluid, but as composed of an infinity of parts, or different molecules, such as oily, mucilaginous, watery, subtle, and grosser saline particles, being carried by the arteries into the gland, divides itself into all the little ramifications of the artery where it is infinitely extended, and wherein all the molecules are obliged to file off, as it were one by one, by the straight passage of the artery into the vein, and consequently to roll over the orifices of the secretory vessels of the glands, whose villous texture is before saturated with a juice of a certain nature; and these particles, which are of the same nature with that juice which presents itself at the orifice or entrance of the secretory vessels, join themselves to it, and enter with the greater liberty, being pushed on by those that follow them; so that they successively run thro' the whole vessel, and at length pass out by the excretory canal; whilst the others, which are not of the same nature, roll over the orifice of the secretory vessels, without ever mingling with the juice they meet there, and pass on to the returning vein to go to the heart again.

SECT, *Secta*, a collective term, comprehending all such as follow the doctrines and opinions of some famous divine, philosopher, &c. See the articles **HERESY** and **SCHISM**.

SECTION, in general, denotes a part of a divided thing, or the division itself. Such, particularly, are the subdivisions of a chapter; called also paragraphs and articles: the mark of a section is §.

SECTION, in geometry, denotes a side or surface appearing of a body or figure cut by another; or the place where lines, planes, &c. cut each other.

The common section of two planes is always a right line; being the line supposed to be drawn on one plane by the section of the other, or by its entrance into it.

SECTION of a Building, in architecture, is the same with its profile; or a delineation of its heights and depths raised on a plane, as if the fabric was cut asunder to discover its inside.

Conic SECTIONS, in geometry. See the articles **CONE** and **CONIC**.

SECTOR, a mathematical instrument, of great use in finding the proportion between quantities of the same kind, as between lines and lines, surfaces and surfaces, &c. for which reason the French call it the compass of proportion.

The great advantage of the sector above common scales, &c. is, that it is adapted to all radii, and all scales. For, by the line of chords, sines, tangents, &c. on the sector, we have lines of chords, sines, tangents, &c. adapted to any radius betwixt the length and breadth of the sector, when opened.

The sector is founded on the fourth proposition of the sixth book of Euclid, where it is demonstrated, that similar triangles have their homologous sides proportional. An idea of its foundation or theory may be conceived from what follows: Let the lines *AB*, *AC* (plate CXIII. fig. 9.) represent the two legs of the sector, and *AD*, *AE*, two equal sections from the center. If now the points *BC* and *DE* be connected, the lines *BC* and *DE* will be parallel; therefore the triangles *ADE*, and *ABC*, will be similar, and consequently the sides *AD*, *DE*, *AB*, *BC*, proportional; that is, as *AD*:*DE*:*AB*:*BC*; whence, if *AD* be the half, third, or fourth part of *AB*, *DE* will be a half, third, or fourth part of *BC*. Whence it follows, that, if *BC* be the chord, sine, tangent, &c. of any number of degrees to the radius *AB*, *DE* will be the same to the radius *AD*.

Description of the SECTOR.—This instrument consists of two equal legs, or rules of brass, &c. riveted together,

but so as to move easily on the rivet; (see fig. 10.) on the faces of the instrument are placed several lines; the principal of which are the line of equal parts, line of chords, line of sines, line of tangents, line of secants, and line of polygons.

The line of equal parts, called also the line of lines, marked *L*, is a line divided into 100 equal parts, and, where the length of the leg will allow it, each of these is subdivided into halves and quarters. It is found on each leg, on the same side, and the divisions numbered 1, 2, 3, 4, 5, &c. to 10, which is near the extremity of each leg. Note, in practice, 1 represents either 1, 10, 100, 1000, 10000, &c. as occasion requires, in which case, 2 represents 2, 20, 200, 2000, 20000, &c. and so of the rest.—The line of chords, marked *C* on each leg, is divided after the usual manner, and numbered 10, 20, 30, &c. to 60.—The line of sines, denoted on each leg by the letter *S*, is a line of natural sines, numbered 10, 20, 30, &c. to 90.—The line of tangents, denoted on each leg by the letter *T*, is a line of natural tangents, numbered 10, 20, 30, &c. to 45. Besides which there is another little line of tangents on each leg, commencing at 45°, and extending to 75, denoted by the letter *t*.—Line of secants, denoted on each leg by the letter *s*, is a line of natural secants, numbered 10, 20, 30, &c. to 75, not commencing at the center of the instrument, but at some distance therefrom.—The line of polygons, denoted by the letter *P* on each leg, is numbered 4, 5, 6, &c. to 12, which falls considerably short of the center of the instrument.

Besides these lines, which are essential to the sector, there are others placed near the outward edges on both sides, and parallel thereto, which are in all respects the same as those on Gunter's Scale, and used after the same manner. Such are the lines of artificial sines marked *S*, of artificial tangents marked *T*, and Gunter's line of numbers marked *N*; these lines do not extend to the end of the instrument. There are, sometimes, other lines placed, to fill the vacant spaces, as the lines of hours, latitudes, and inclination of meridians, which are used the same as on the common scales.

The lines found by the sector are of two kinds, lateral and parallel; the first are such as are found by the sides of the sector, as *AB*, *AC* (fig. 11.) the latter such as go across from one leg to the other, as *DE*, *BC*. Note, the lines are not placed in the same order on all sectors, but they may be easily found by the above directions.

Use of the Line of equal Parts on the SECTOR.—1. To divide a given line into any number of equal parts, suppose seven. Take the given line in your compasses, and, setting one foot in a division of equal parts, that may be divided by seven, for example, 70, whose 7th part is 10, open the sector till the other point fall exactly on 70, in the same line on the other leg. In this disposition, applying one point of the compasses to 10, in the same line, shut them till the other fall in 10, in the same line, on the other leg, and this opening will be the 7th part of the given line. Note, if the line to be divided be too long to be applied to the legs of the sector, divide only one half, or one fourth by 7, and the double or quadruple thereof will be the seventh part of the whole.

2. To measure the lines of the perimeter of a polygon, one of which contains a given number of equal parts. Take the given line in your compasses, and set it parallel upon the line of equal parts, to the number on each leg expressing its length. The sector remaining thus, set off the length of each of the other lines parallel to the former, and the numbers each of them falls on, will express their lengths.

3. A right-line being given, and the number of parts it contains, suppose 120, to cut from it any number of the same parts, suppose 25. Take the given line in your compasses, open the sector till the two feet fall on 120 on each leg; then will the distance between 25 on one leg, and the same number on the other, give the parts required.

4. To multiply by the line of equal parts on the sector.—Take the lateral distance from the center of the line to the given multiplicator; open the sector till you fit that lateral distance to the parallel of 1 and 1, or 10 and 10, and keep the sector in that disposition; then take in

the compasses the parallel distance of the multiplicand, which distance, measured laterally on the same line, will give the product required. — Thus, suppose it were required to find the product of 8, multiplied by 4: Take the lateral distance from the center of the line to 4 in your compasses, i. e. place one foot of the compasses in the beginning of the divisions, and extend the other along the line to 4. Open the sector till you fit this lateral distance to the parallel of 1 and 1, or 10 and 10. Then take the parallel distance of 8, the multiplicand; i. e. extend the compasses from 8, in this line, on one leg to 8 in the same line on the other, and that extent, measured laterally, will give the product required.

5. To divide by the line of equal parts on the sector. — Extend the compasses laterally from the beginning of the line to 1, and open the sector till you fit that extent to the parallel of the divisor; then take the parallel distance of the dividend, which extent, measured in a lateral direction, will give the quotient required. Thus suppose it was required to divide 36 by 4; extend the compasses, laterally, the beginning of the line to 1, and fit to that extent the parallel of 4, the divisor; then extend the compasses parallel, from 36 on one leg, to 36 on the other, and that extent, measured laterally, will give 9, the quotient required.

6. To work any proportion by the sector. — Take the second term lateral, and, opening the sector, apply that extent parallel in the first term, and stay the sector in that position; then take the parallel distance of the third term, which extent, measured laterally, gives the fourth term required. This is so easy, from what has already been said, that it needs no example.

1. The use of the line of chords on the sector. — 1. To open the sector so as the two lines of chords may make an angle or number of degrees, suppose 40. Take the distance from the joint to 40, the number of the degrees proposed, on the line of chords; open the sector till the distance from 60 to 60, on each leg, be equal to the given distance of 40; then will the two lines on the sector form an angle of 40 degrees, as was required.

2. The sector being opened, to find the degrees of its aperture. Take the extent from 60 to 60, and lay it off on the line of chords from the center; the number whereon it terminates will shew the degrees, &c. required.

3. To lay off any number of degrees upon the circumference of a circle. Open the sector till the distance between 60 and 60 be equal to the radius of the given circle; then take the parallel extent of the chord of the number of degrees, on each leg of the sector, and lay it off on the circumference of the given circle. Hence any regular polygon may be easily inscribed in a given circle.

Use of the Line of Polygons on the SECTOR. — 1°. To inscribe a regular polygon in a given circle. Take the semi-diameter of the given circle, in the compasses, and adjust it to the number 6, on the line of polygons, on each leg of the sector: then, the sector remaining thus opened, take the distance of the two equal numbers, expressing the number of sides the polygon is to have; e. gr. the distance from 5 to 5 for a pentagon, from 7 to 7 for a heptagon, &c. These distances carried about the circumference of the circle will divide it into so many equal parts.

2°. To describe a regular polygon, e. gr. a pentagon, on a given right line. Take the length of the line in the compasses, and apply it to the extent of the number 5, 5, on the lines of polygons. The sector thus opened, upon the same lines take the extent, from 6 to 6; this will be the semi-diameter of the circle the polygon is to be inscribed in. If, then, with this distance, from the ends of the given line, you describe two arches of a circle, their intersection will be the center of the circle.

3°. On a right line, to describe an isosceles triangle, having the angles at the base double that at the vertex. Open the sector, till the ends of the given line fall on 10 and 10 on each leg; then take the distance from 6 to 6. This will be the length of the two equal sides of the triangle.

Use of the Lines of Sines, Tangents, and Secants, on the SECTOR. — By the several lines disposed on the sector, we have scales to several radius's; so that having a length,

or radius, given, not exceeding the length of the sector when opened, we find the chord, sine, &c. thereto. Ex. gr. Suppose the chord, sine, or tangent, of 10 degrees, to a radius of 3 inches, required: make 3 inches the aperture, between 60 and 60, on the lines of chords of the two legs; then will the same extent reach from 45 to 45 on the line of tangents, and from 90 to 90 on the line of the sines on the other side; so that to whatever radius the line of chords is set, to the same are all the others set. In this disposition, therefore, if the aperture between 10 and 10, on the lines of chords, be taken with the compasses, it will give the chord of 10 degrees. If the aperture of 10 and 10 be in like manner taken on the lines of sines, it will be the sine of 10 degrees. Lastly, if the aperture of 10 and 10 be in like manner taken on the lines of tangents, it gives the tangent of 10 degrees.

If the chord, or tangent, of 70 degrees were required; for the chord, the aperture of half the arch, viz. 35, must be taken, as before: which distance, repeated twice, gives the chord of 70°. To find the tangent of 70° to the same radius, the small line of tangents must be used, the other only reaching to 45: making, therefore, 3 inches the aperture between 45 and 45 on the small line; the extent between 70 and 70 degrees, on the same, will be the tangent of 70° to 3 inches radius.

To find the secant of an arch, make the given radius the aperture between 0 and 0 on the line of secants: then will the aperture of 10 and 10, or 70 and 70, on the said lines, give the tangent of 10°, or 70°.

If the converse of any of these things were required; that is, if the radius be required, to which a given line is the sine, tangent, or secant, it is but making the given line, if a chord, the aperture on the line of chords, between 10 and 10, and then the sector will stand at the radius required; that is, the aperture between 60 and 60, on the said line, is the radius. If the given line were a sine, tangent, or secant, it is but making it the aperture of the given number of degrees; then will the distance of 90 and 90 on the sines, of 45 and 45 on the tangents, of 0 and 0 on the secants, be the radius.

Use of the SECTOR in Trigonometry — 1°. The base and perpendicular of a rectangled triangle being given, to find the hypotenuse. Suppose the base AC (plate CXIII. fig. 12) 40 miles and the perpendicular AB 30; open the sector till the two lines of lines make a right angle: then for the base take 40 parts on the line of lines on one leg; and for the perpendicular 30 on the same line on the other leg: then the extent from 40 on the one, to 30 on the other, taken in the compasses, will be the length of the hypotenuse, which line will be found 50 miles.

2°. The perpendicular AB of a right-angled triangle ABC being given, 30, and the angle BCA , 37°, to find the hypotenuse BC . Take the given side AB , and set it over, on each side, upon the sine of the given angle ACB ; then the parallel distance of radius, or of 90 and 90, will be the hypotenuse BC ; which will measure 50 on the line of sines.

3°. The hypotenuse and base being given, to find the perpendicular. Open the sector, till the two lines of lines be at right angles; then lay off the given base on one of those lines from the center. Take the hypotenuse in your compasses, and, setting one foot in the point of the given base, let the other fall on the line of lines, on the other leg: the distance from the center to the point where the compasses fall, will be the length of the perpendicular.

4°. The hypotenuse being given, and the angle ACB , to find the perpendicular. Make the given hypotenuse a parallel radius, i. e. make it the extent from 90 to 90 on the lines of sines; then will the parallel sine of the angle ACB be the length of the side AB .

5°. The base and perpendicular AB given, to find the angle BCA . Lay off the base AC on both sides the sector, from the center, and note its extent: then take the given perpendicular, and to it open the sector, in the terms of the base; the parallel radius will be the tangent of BCA .

6°. In any right-lined triangle, two sides being given with the included angle, to find the third side. Suppose

the side AC (*fig. 13.*) 20, the side BC 30, and the included angle ACB 110° ; open the sector, till the two lines of lines make an angle equal to the given angle, viz. 110° . Lay off the given sides of the triangle from the center of the sector, on each of the lines of lines; the extent between their extremes is the length of the side AB sought.

7°. The angles CAB and ACB given, and the side CB, to find the base AB. Take the given side CB, and turn it into the parallel line of its opposite angle CAB; and the parallel line of the angle ACB will be the length of the base AB.

8°. The three angles of a triangle being given, to find the proportion of the sides. Take the lateral lines of the several angles, and measure them in the line of lines; the numbers answering thereto give the proportion of the sides.

9°. The three sides being given, to find the angle ACB. Lay the sides AC, CB, along the line of lines, from the center; and set over the side AB in their terms: so is the sector opened, in these lines, to the quantity of the angle ACB.

10°. The hypotenuse AC (*fig. 14.*) of a right-angled spherical triangle ABC given, e. gr. 43° , and the angle CAB 20° ; to find the side CB. The rule is: As radius is to the sine of the given hypotenuse 43° , so is the sine of the given angle 20° to the sine of the perpendicular CB. Take therefore 20° from the center, along the line of sines, in your compasses, and set the extent from 90 to 90, on the two legs; and the parallel sine of 43° , the given hypotenuse, will, when measured from the center or the line of sines, give $13^\circ 30'$ the side required.

11°. The perpendicular BC, and the hypotenuse AC being given, to find the base AB. — As the sine complement of the perpendicular BC is to radius, so is the sine complement of the hypotenuse to the sine complement of the base. — Make therefore the radius a parallel sine of the given perpendicular, then the parallel sine of the hypotenuse measured along the line of sines will give the complement of the base required.

SECULAR, something that is temporal, in which sense the word stands opposed to ecclesiastical: thus we say, secular power, secular jurisdiction, &c.

Secular is more peculiarly used for a person who lives at liberty in the world, not shut up in a monastery, nor bound by vows, or subjected to the particular rules of any religious community; in which sense it stands opposed to regular. The Romish clergy is divided into secular and regular.

SECULAR GAMES, *Ludi Seculares*, in antiquity, solemn games held among the Romans once in an age. These games lasted three days and as many nights, during which time sacrifices were performed, theatrical shews exhibited, with combats, sports, &c. in the circus. The occasion of these games, according to Valerius Maximus, was to stop the progress of a plague. The first who had them celebrated at Rome was Valerius Publicola, the first consul created after the expulsion of the kings. The ceremonies to be observed therein were found prescribed in one of the books of the Sibyls. At the time of the celebration of the secular games, heralds were sent throughout all the empire, to intimate that every one might come and see those solemnities which he never yet had seen, nor was ever to see again. Authors are not agreed as to the number of years wherein these games returned, partly because the quantity of an age or *seculum*, among the ancients, is not known, and partly on other accounts; some will have it that they were held every hundred years, and that the *seculum* or age was our century.

SECULAR POEM, *Carmen Seculare*, a poem sung or rehearsed at the secular games, of which kind we have a very fine piece among the works of Horace, being a Sapphic ode at the end of his Epodes.

SECULARIZATION, the act of converting a regular person, place, or benefice, into a secular one.

SECUNDINES, *Secundinae*, in medicine, the several coats or membranes inclosing the foetus in the womb. These are the chorion, amnios, and allantois.

It very often happens that these are retained in the womb after child-birth, and great mischiefs ensue from

it. The assistance of a skilful hand is, in many cases, necessary to the getting them out; and this is to be done with great care and speed, before the uterus closes itself upon them, otherwise, they occasion terrible hæmorrhages, faintings, and often inflammatory and putrid fevers.

The patient herself may greatly promote the expulsion of these, by any forcible emotion of the body, as by a forced cough, or by sneezing; the midwife at the same time is gently to pull them by the navel-string, but this must be done very cautiously, for fear of its breaking. If this fails, the cautious introducing the hand often sets all right, or the use of gently pellent medicines may be called in; and to these may be added broths, with saffron in them, and by the use of common clysters great good is often done: but, if after all this care there yet remain some fragments of them behind, there usually arises a fever within twelve hours; and, in this case, the utmost care must be taken to prevent putrefaction, and expel the remains of them. To these purposes medicines prepared with myrrh, amber, saffron, and the cortex Eleutherii, are of the greatest service; and to these may be added occasionally the colliquating and attenuating salts, such as tartarum vitriolatum and nitre. *Junker's Consp. Med.*

SECURIDACA, in botany, a genus of plants, the corolla whereof is papilionaceous; the vexillum is roundish and very large; the alæ are obtuse, and the carina lunulated. The fruit is roundish, ending in a very large, oblong, obtuse, perpendicular membrane, broadest above; the seed is single, and is invested with the whole pericarpium.

This plant taken inwardly is good for the stomach, and is an ingredient in antidotes used in a pessary with honey before coition, supposed to prevent conception.

SECURIDACA is also the name whereby some authors call the coronilla. See CORONILLA.

SECURITATE PACIS, in law, a writ lying for a person who is threatened with danger from another against him that threatens; it issues out of the court of chancery, and is directed to the sheriff, &c.

SEDANTIA, SEDATIVE MEDICINES, in pharmacy, such medicines as are possessed of a power not only of composing, checking, and allaying the exorbitant and irregular motions of the solids and fluids, but also of alleviating and resolving the painful spasmodic strictures of the parts.

As the effect of these medicines are very extensive, we may justly include in their number paretics, which not only relax and gently sooth the rigid fibres, but also obtund the acrimony of the juices; anodynes, which alleviate the violence of racking pains; antispasmodics, which mitigate and remove the spasmodic strictures of the parts; antiepileptics, which check convulsive motions; hypnotics, which procure sleep; and narcotics, which induce a considerable stupor of the senses and torpor of all the motions of the body.

SE DEFENDENDO, in law, a plea used for him that is charged with the death of another, by alledging that he was under a necessity of doing what he did in his own defence; as that the other assaulted him in such a manner, that if he had not done what he did, he must have been in hazard of his own life. But here the danger must appear so great, as to be inevitable.

SEDIMENT, the settlement or dregs of any thing, or that gross heavy part of a fluid body which, upon resting, sinks to the bottom of the vessel.

SEDER OLAM, a Hebrew term, literally signifying order of the world; being the titles of two chronicles in that language. They are both very short, though the one more so than the other; whence one is called Seder Olam Rabba, the Great Seder Olam; and the other Seder Olam Zuta, the Lesser Seder Olam.

The Great Seder Olam commences at the creation of the world, and comes down as low as the war of the pseudo-Messiah Barchochabab, under Adrian, fifty-two years after the destruction of the temple of Jerusalem, and, of consequence, to the 122d year of Christ. It is almost all taken from the scripture, excepting the end. It is the work of R. Josa, son of Hhelpeta of Trippora, who lived in the second century, about the year one hundred

undred and thirty, and was master of the famous R. uda Hakkadosch, the compiler of the Mischna.

The Lesser Seder Olam is an abridgment of the former, brought down as far as Mar Sutra, who lived four hundred and fifty years after the destruction of the temple of Jerusalem, or five hundred and twenty years after Christ. F. Morin, continually bent upon diminishing the antiquity of the principal books of the Jews, endeavours to prove it to have been wrote about the year of Christ one thousand one hundred and twenty-four, as indeed is expressed at the beginning: but R. Dav. Gantz has overthrown this opinion in his Tsemahh David, and shewn, that the date, in the beginning, is an interpolation.

The two chronologies were first printed at Mantua in 1514, quarto; again, at Basil, by Frobenius, in 1580, octavo: at Venice in 1545, quarto: at Paris, with a Latin version of Genebrard, in twelves. They have been since reprinted at Amsterdam, in 1711.

SEDR, or SEDRE, the high priest of the sect of Ali among the Persians.

SEDUM, in botany, a genus of plants, the corolla whereof consists of five acuminate, lanceolated, plane, patent petals; the fruit consists of five erecto-patent, acuminate compressed capsules, emarginated towards the base, and opening longitudinally upwards and downwards; the seeds are numerous and small.

This genus comprehends the sedum, or house-leek, orpine, wall-pepper, and other species: all which agree in virtues with orpine. See ORPINE.

SEED, *Semen*, a matter prepared by nature, for the reproduction and conservation of the species, both in animals and vegetables.

Seed, in the animal œconomy, is a white, liquid matter separated from the blood in the testicles, and reserved for the purpose of generation. See the article GENERATION.

SEED, in botany, the product of a plant, whereby the species is propagated. The seed is frequently the fruit of the plant; sometimes it is only a part inclosed in the fruit, &c.

Dr. Agricola tells us that there is inclosed in seeds a little germ or bud that composes the prime and most noble part of the whole; and which, according as some curious persons have calculated, hardly makes the thousandth part of the seed; but, on this small part, the image and representation of the whole tree is perfectly delineated and expressed; and this principal part being any way hurt, spoiled, or lost, the seed, however large or otherwise perfect, will come to nothing, but will rot in the earth.

In Malpighi's Life, p. 67, a debate may be seen between him and signior Triumphetti, whether the whole plant be actually in the seed: the affirmative is maintained by Malpighi with cogent arguments.

And, as the perpetuity and safety of the species depend upon the safety of the seed and fruit in a great measure, nature hath taken peculiar care for the conservation and safety thereof; as particularly in such as dare to shew their heads all the year, how securely is their flower, seed, or fruit, locked up all the winter, together with their leaves and branches, in their germs, and well-fenced and covered there with neat and close tunics? And, for such as dare not so expose themselves, with what safety are they preserved under the coverture of the earth, in their root, seed, or fruit, till invited out by the kindly warmth of the spring? And, when the whole vegetable race is thus called out, it is very curious to observe the methods of nature in guarding those insensitive creatures against harms and inconveniencies, by making some, for instance, to lie down prostrate, and others to close themselves up upon the touch of animals; and the most to shut up their flowers, their down, or other their like guard, upon the close or cool of the evening, for fear of rain, or other matters that may be prejudicial to the tender seed.

And to these considerations, relating to the seed, we might add the various ways of nature in dissipating and sowing it, some being, for this end, winged with light down or wings to be conveyed about by the winds; others being laid in elastic springy cases, that, when they burst and crack, dart their seed at convenient distances,

performing thereby the part of a good husbandman; others, by their agreeable taste and smell, and salutary nature, inviting themselves to be swallowed, and carried about by the birds, and thereby also fertilized by passing through their bodies; and others, not thus taken care of, do many of them, by their usefulness in human life, invite the husbandman and gardener carefully to sow and nurse them up. Dr. Agricola says, the seeds of fruits, when separated from them, though not kept in the earth, will live fresh and healthy a great many years by means of its intrinsic spirit; but, when it grows very old, it is unfit for vegetation.

But, notwithstanding what some gardeners say, that some seeds are the better for being two or three years old; yet, he is of opinion that seed of one year old is best: for then the spirit is fresh and lively; the juices, which are the principle of nutrition and growth, are still susceptible of motion in the places of their residence; and the whole structure is in a good disposition.

The vegetative principle will indeed remain longer in one seed than in another, and in the long and round seed longer than in the flat and small seed; for that in the large and round seed, as well as in the oval, the juices circulate more freely by an interior motion, and have a greater circuit. And, besides that the juices are in them in greater abundance than in those that are small and flat, they can neither evaporate or dry so soon.

But, in those seeds that are very old, the juices are consumed and dried, and the organs are otherwise modified; and so the moving vegetative principle can act no longer for the fecundity of plants for the production of seeds.

Change of SEED, a term used by the farmers to express the common, and, as they suppose, necessary custom, of changing among one another the seed of their lands, as wheat, and the like; it being a received opinion, that the seed produced on one land will grow better on another, than on that which produced it, though the same species of plant be sown.

Seeds, in their natural climate, do not degenerate, unless culture has improved them; they then indeed are liable, upon omission of that culture, to return to their natural state again. Whatever benefit arises to the farmer from the changing the seed of the same species, is from causes which are themselves the effects of different climates, such as heat and moisture, which may vary very much in the same neighbourhood. There is a mountain in the Mogul's country, which on the south side produces Indian plants, and on the north side European ones, from different exposures. Some land retaining water longer is colder, and some letting it pass off quicker is warmer; as it may also be from the nature and figure of its parts, which retain more of the sun's heat than others. Sandy and gravelly grounds are always warmer than others, if they have some hollow and spongy stratum underneath, that will let the water pass off.

The benefit arising from the change of seed is owing to these changes, not to the change of food; and these causes shew their effects chiefly in the generation of the seed. Flax seed, brought from Holland, and sown here, will produce as fine flax as it does there, but, in the next generation, it will degenerate, become coarser; by this means it will continue to degenerate every year, till after two or three years it is no better than our own seed produces, and yet the land shall be as good for this coarse sort, as when it produced the fine; so also it is, when the seeds of our own wheat are changed between farmer and farmer. And thus silk-worms hatched and bred in France of eggs brought from Italy, will make as fine silk as the Italian; but the eggs of those laid in France will produce worms that make no better silk than those produced in France, though their food is all the while the same.

Common barley, once sown in the burning sands in Wiltshire, will for many years after, if sown on indifferent warm ground, be ripe sooner than any other barley by two or three weeks; but, if sown on cold grounds farther north, it will be as late as any other barley, after two or three years. The weeds, which perplex the farmers in every field, grow as strong and troublesome one year

year as another, and that without any change of seed at all. These seem therefore to have been the natural produce of our soil, and corn and other useful plants to have been brought from other places, and improved by culture; these will therefore no longer retain their perfection and value, than such culture is continued to them.

Laurembergius has carried this notion of degeneracy and change from the soil, so far as to affirm that wheat will, in some places, degenerate into rye; and in other places, rye will be exalted into wheat by the soil: but those who are acquainted with botany know, that a horse might as soon be changed into a bull by feeding in an improper pasture, as one plant degenerate into another by fault of the soil. *Tull's Husbandry*.

SEEDLINGS, among gardeners, denote such roots of gillyflowers as spring from seed; also the young tender shoots of any plants that are newly sowed.

SEEDY, in the brandy trade, a term used by the dealers to express a fault that is found in several parcels of French brandy, which renders them unsaleable. The French suppose that these brandies obtain the flavour which they express by this name, from the weeds which grow among the vines, from whence the wine, of which this brandy was made, was pressed.

However it be, the thing is evident, and the taste not of any one kind; but some pieces of brandy taste strongly of aniseed, some of caraway seed, and some of other of the strong flavoured seeds of plants, principally of the umbelliferous kind; so that it shall be rather taken for aniseed, caraway, or some other water, than for brandy.

The proprietor of such brandies is always at great trouble to get them off, and usually is reduced to the necessity of mixing them in small quantities with pieces of other brandies, so as to drown and conceal the taste; and, where he has not opportunities of doing this, is obliged to sell them on very disadvantageous terms.

The business of rectification of spirits is very little understood abroad, though very much practised with us; and a man in France or Holland, who could take off this taste from these brandies, might get great advantages by it. There is no doubt but that the same means which we use to rectify malt spirits, that is, to clear it of its nauseous and stinking oil, which always rises with it in the first distillation, would also serve to purify these brandies, and, by leaving these extraneous oils behind, render them as well tasted as any others; since there is no question, but that the oil of malt, which is a principle of the same ingredients with the spirit, is more firmly united to it than flavouring oils in the brandy, which are not the produce of the grape, but of some foreign matter only accidentally mixed with it.

It is a mistake to imagine, that all the brandies made in France are so fine as those which we meet with on the keys of London; on the contrary, there are many hundred pieces made every year, which are as badly flavoured as our coarsest malt spirit: but the case is this, they send the best brandies and the best wines to England, where they can get the best prices for them. In Holland, on the contrary, the mart of goods of all sorts, it is sometimes difficult to pick one piece of good brandy out of fifty, the general run of them being either seedy, musty, oily, or otherwise infected with some unnatural and disagreeable flavour; and these are the sorts which in France they despair of curing by re-distillation, or bringing to the state of three fifths, or trois cinques, as they express their stronger brandies. *Shaw's Essay on Distillery*.

SEEING, the act of perceiving external objects by means of the eye, thence called the organ of sight.

SEELING, a term used by dealers in horses to denote a small spot of white hairs growing among the natural ones on the eye-brow; and which is a certain mark of old age. A horse is said never to feel before he is fourteen, and always does so before he is sixteen.

SEGMENT of a Circle, in geometry, a part of a circle, comprehended between an arch and the chord thereof.—Or it is a part of a circle less than a semicircle, comprehended between a right line, and a part of the circumference.

Thus the portion A E B A (plate CXIV. fig. 1.) comprehended between the arch A F B and the chord A B, is a segment of the circle A B E D.

As it is evident every segment of a circle must either be greater or less than a semi-circle, the greater part of the circle cut off by a chord, i. e. the part greater than a semi-circle, is called the greater segment, as A D E B; and the part less than a semi-circle, the lesser segment, as A F B.

The angle which the chord A B makes with a tangent L B, is called the angle of a segment.

Line of SEGMENTS. See SECTOR.

SEGMOIDAL Valves, in anatomy, are small valves situated in the pulmonary artery, resembling segments of circles, whence they had their name.

SEIGNORAGE, a right or due belonging to a seigneur or lord.

It also implies a right or due belonging to a prince for the coining of money.

SEIGNORY, a manor or lordship.

SEISIN, in law, implies possession; and is of two kinds; seisin in law, and seisin in fact. The former signifies something done, which the law accounts a seisin; as an enrollment, &c. And the latter an actual and corporal possession taken.

SEISURE, in commerce, implies the arresting some goods, merchandize, &c. either by express order of the sovereign, or in consequence of some law.

SEIZING, among sailors, the act of fastening any two things together with a cord or line: also the cord or line which fastens them.

SELANDERS, in farriery, the same with melanders. See MELANDERS.

SELENITÆ, moon-stone, in natural history, form a particular class of fossils of a rhomboidal, pellucid form, divisible into laminæ.

SELENOGRAPHY, that part of cosmography which relates to the moon. See the article MOON.

The word is formed from the Greek, *σεληνη*, the moon, and *γραφω*, to describe.

SELEUCIDÆ, a race of Grecian kings who reigned as successors of Alexander the Great in Syria.—Their establishment is a celebrated æra in chronology, called the Syro-Macedonian æra, or that of the Seleucidæ; and which, according to the best authors, began 12 years after the death of Alexander the Great, and 311 before Christ.

SELF-Opens, a term used by the miners in the north of England to express certain natural cavities or chambers, which are frequently met with, some near the surface, some at very great depths, some small, and others very large.

These are of various figures, and often run into strange sinuses. Dr. Lister, in accounting for the origin of earthquakes, supposes the whole crust of the earth to be more or less hollowed in this manner; which he also argues for, from the streams of waters which arise in large quantities from the sides of mountains, and must have communication with these self-opens, and supplies from them.

The natural hollows the doctor thinks to be the means of continuing and propagating earthquakes; the first cause of which he ascribes to the breath of the pyrites, which he also says is the pyrites itself *totâ substantiâ*. This he observes takes fire of itself, on being exposed to the air in our sight, and may do so, from various other causes, under-ground. The sulphureous smell of the air and waters, before and after earthquakes, in the places where they happen, seems a proof that they owe their origin to some such sulphureous matter as this stone; and the rolling and desultory noise of an earthquake, seems also to shew that it is not expanded any way at once, but is propagated through a chain of these subterranean hollows.

It is not necessary that we should suppose a continued chain of them, from the place where the earthquake begins to be felt, to the spot where it ends; but, if there are many of them irregularly scattered about the earth, the force of the explosion will be sufficient to burst thro' the solid parts between, and open a passage from one to the others, which may continue open no longer than

the force continues, and after the shock is over close together again, so as to leave no trace where it was.

Our miners not only find the natural caverns, but they also find them often full of what they call fire damp, which are inflammable vapours, of the very nature of those which occasion earthquakes, and, when fired, make the same explosions, and cause the same effects in a certain degree. These sometimes require a candle, or other actual fire, to come in contact, in order to kindle them; but sometimes they are found kindled of themselves, and flaming on the surface of the waters, in the bottoms of the pits, or at the fissures of the coal. *Philos. Transf.* N^o. 157.

SELL, among builders, implies the lowest piece of timber in a timber-building, being that on which the whole superstructure is raised. It is also applied by some to the bottom part of a window frame.

SELLA *Equina, Turcica, or Sphænoïdes*, in anatomy, imply the four apophyses of the os sphænoïdes in the brain. They have the name from their resembling a saddle, which the Latins called *sella*.

SELVAGE, among sailors, a sort of strop or wreath formed to fasten on any particular rope, whereby to hook a tackle. See the article TACKLE.

SEMRADOR, an instrument invented by Don Joseph de Lucatello, for the more evenly sowing of seeds, and in many particulars resembles the drill-plough of Mr. Tull.

SEMEIOTICA, that part of medicine which treats of the signs of health and diseases.

The word is formed from the Greek, *σημειον*, a sign.

SEMEN, *Seed*. See the article SEED.

SEMETs, in botany, the same with antheræ. See ANTHERÆ.

SEMI, a word borrowed from the Latin, which signifies half. It is used only in composition with other words.

SEMI-ARIANS, a branch of the Arian heretics, so called, from their pretending to condemn the errors of Arius, though they in reality maintained his principles; the only difference consisting in their palliating and concealing them under softer and more moderate terms. They would not allow, with the Catholics, that the Son was *ομοιος*, of the same substance, but only *ομοιουσι*, of a like substance with the Father: and therefore, tho' they differed from the orthodox in a single letter only, yet, in effect, they denied the divinity of Christ, and placed him in the rank of creatures.

SEMI-BREVE, in music, a note or measure of time, being equal to half a breve, three minims, four crotchets, &c.

SEMI-CIRCLE, in geometry, a figure comprehended between the diameter of a circle, and half the circumference.

SEMI-COLON, one of the stops used by grammarians to distinguish the different members of a sentence. It is marked thus (;) and implies a shorter pause than a colon, whence it has its name. See the article PUNCTUATION.

SEMI-CUBICAL PARABOLA, a name given by mathematicians to a curve of the second order, wherein the cubes of the ordinates are in proportion to the squares of the abscissæ.

SEMI-CUPIUM, a half bath, in which the parts of the patient below the navel only are immersed.

SEMI-DIAMETER, half the diameter, or radius, being a line drawn from the center of a circle or sphere to its circumference. See the article RADIUS.

SEMI-DIAPENTE, in music, a false or defective fifth.

SEMI-DIAPASON, in music, a false or defective octave.

SEMI-DIATESSARON, in music, a defective or false fourth.

SEMI-FLOSCULOUS, in botany, implies the flowers of a class of flowers whose petals are hollow in the lower part, but in the upper flat, and continued in the shape of a tongue. The dandelion, hawkweed, &c. are of this kind.

SEMI-LUNAR VALVES, in anatomy, are three small membranous valves of a semi-lunar figure placed

in the orifice of the pulmonary artery, to prevent the blood's flowing into the heart at the time of its dilatation.

SEMI-MEMBRANOSUS, a long thin membranous muscle, situated on the backside of the thigh, and arises from the tubercle of the ischium. It is one of the fluxors of the tibia.

SEMINAL, spermatic, or something belonging to the seed.

SEMINARY, in popish countries, are certain colleges appointed for the instruction and education of young persons destined for the sacred ministry. The first institution of such places is ascribed to St. Augustine. And the council of Trent decrees, that children exceeding twelve years of age shall be brought up, and instructed in common, to qualify them for the ecclesiastical function, and that there shall be a seminary of such belonging to each cathedral, under the direction of the bishop.

SEMINARY, in gardening, implies the seed-plot, or piece of ground allotted for raising plants from seed, and keeping them till they are fit to be removed into the garden or nursery.

SEMINATION, in agriculture, the act of sowing, or scattering the seed.

SEMI-NERVOSUS, half nervous, in anatomy, a muscle arising from the protuberance of the ischium, and inserted, by a round tendon, into the internal part of the epiphysis of the tibia, and helps to bend the leg.

SEMI-ORDINATE, half of an ordinate. See ORDINATE.

SEMI-PELAGIANS, christian heretics, so called from their being a branch of the Pelagians. See PELAGIANS.

They pretended to keep a mean between the Pelagians and the orthodox, but in fact agreed with neither. They allowed original sin, with the orthodox, but denied that the liberty of the will could be so impaired thereby, that men could not of themselves do something which might induce God to afford his grace to one more than another. They taught that the grace by which men are saved, is not given them by the mere will of God, but according to his eternal prescience, by which he foresaw who they were that would believe in him. As to election, they held that it depended on our perseverance: God chusing such only to eternal life, as continued steadfast in the faith.

Cassian, who had been a deacon of Constantinople, and was afterwards a priest of Marseilles, was the chief of the Semi-pelagians. St. Prosper, in a letter to St. Augustine, calls them *Reliquias Pelagii*.

SEMI-QUAVER, in music, a note whose length is equal to half a quaver.

SEMIS, among the ancient Romans, was equal to half the as. See AS.

SEMISPINALIS *Colli*, in anatomy, a name given to all that fleshy mass which lies between the transverse and spinal apophysis, from the second vertebræ of the neck, to the middle of the back; the splenius and the complexus major, which cover it, having been raised.

It is composed of several oblique converging muscles, which may be divided into external and internal; and of these the external are the longest.

The external are fixed below the transverse apophysis of the sixth, seventh, eighth, or ninth upper vertebræ of the back, by tendinous extremities, which, as they ascend, become fleshy and mix with each other. Their superior insertions in the neck are six in number, of which the first, which is tendinous, is in the seventh spinal apophyses; the rest, which are fleshy, are in the five next spinal apophyses.

The lowest of these external muscles arise more or less, by some communicating fleshy fibres with the spinalis longissimus and semi-spinalis dorsi.

The internal are shorter and more oblique than the external, and partly covered by them. They are fixed by their lower extremities to the transverse apophysis of the third or fourth upper vertebræ of the back, and to the oblique apophysis of the fourth or fifth lower vertebræ of the neck, and by their other extremities they are inserted in the sixth spinal apophyses of the neck. Some of these internal muscles are very short, lying wholly between

the spinal apophyses and the oblique or transverse apophyses next them.

The semi-spinalis or transverse spinales of both sides, acting together, extend the neck upon the trunk, to keep it from inclining forward in standing or sitting, and bend it backward. The semi-spinales of one side, acting alone, produce the same motions in an oblique direction, and in that case are assisted by the inferior or vertebral portion of the neighbouring splenius under which they cross.

The semi-spinales of both sides may also serve for the rotation of the neck, but then the inferior splenius of the opposite side must assist them. This motion is made in the ordinary situation of the neck, principally on the fourth and fifth vertebræ. They may also perform the lateral inflections of the neck, by assisting the longus colli and anterior vertebral muscles of the same side.

SEMI-SPINALIS Dorsi, in anatomy, a fleshy mass, which, from all the spinal and transverse apophyses of the back and loins, is extended in distinct fasciculi over the vertebræ themselves. It is made up like that of the neck of several oblique, converging, vertebral muscles, the uppermost of which is fixed below to the third transverse apophysis of the loins, and above to the last spinal apophysis of the back.

They may be divided into external, which are first discovered, and internal, which lie immediately on the vertebræ. The external, from the first vertebræ to the seventh inclusively, appear to be longer than the internal, which are covered by them. They may also be distinguished into those which go from one transverse to several apophyses, and those which go from several transverse to one spinal apophysis.

The semi-spinales, or transverse spinales, being oblique, converging, vertebral muscles, are assistants to the sacro-lumbaris and longissimus dorsi, which they cross on each side. By this decussation, joined to the multiplicity and graduated distribution of their insertions, they increase the strength of the other muscles considerably, whether they act equally and uniformly with them, or alternately. The lumbar semi-spinales, called by the ancients musculus sacer, because of their insertions in the os sacrum, are more exposed to motions and strains, than those of the back, and are also larger and thicker. They are much better fitted than the sacro-lumbares for supporting the pelvis on both sides in walking, and on one side when we raise the foot on that side, and support ourselves on the other. *Winslow's Anat.*

SEMITA LUMINOSA, a name given by astronomers to a lucid tract in the heavens, visible about six o'clock at night, a little before the vernal equinox. It extends from the western edge of the horizon up towards the Pleiades.

Cassini was of opinion that this lucid tract was owing to a vast number of planets encompassing the sun, whose light they reflected.

SEMPERVIVUM, houseleek, the name of a well-known plant, which is used in medicine as a cooler.

SENA, the leaf of an annual, woody, pod-bearing plant, brought dry from Alexandria in Egypt. It is of a lively yellowish green colour, an oblong somewhat oval figure, sharp-pointed at the ends, about a quarter of an inch broad, and not a full inch in length. Some inferior sorts are brought from Tripoli and other places: these may be distinguished, by their being either narrower, longer, and sharper-pointed; or larger, broader, and round-pointed, with small prominent veins; or large, obtuse, and of a fresh green colour, without any yellow cast.

Sena is a moderately strong, and in general a safe cathartic: Geoffroy specifies hemorrhages, inflammations of all kinds, and disorders of the breast, as being almost the only exceptions to its use. The dose in substance is from a scruple to a dram; in infusion, from one dram to three or four. It gives out its virtue both to watery and spirituous menstrua: to water and proof spirit it communicates a brownish colour, more or less deep according to the proportions; to rectified spirit, a fine green. There are two inconveniencies often complained of in this medicine; its being liable, in some constitutions, to

occasion gripes; and its being accompanied with an ill flavour, which is apt to nauseate both the stomach and the palate. The first may be obviated by dilution, the latter by aromatic and other additions: several compositions of this kind are prepared in the shops, both sufficiently palatable, and which operate with ease and mildness.

Six drams of tamarinds and two of crystals of tartar are boiled in a pint and a half of water, till half a pint is wasted, and the strained liquor poured boiling hot upon one, two, or three drams of sena: after maceration for four hours, the strained infusion is sweetened with an ounce of syrup of violets, and flavoured with half an ounce of simple cinnamon water. Three drams of sena are infused in a quarter of a pint of boiling water, for four hours, or till the liquor has grown cold; with the addition of a scruple of ginger; or with half a dram of lesser cardamom seeds husked, and three fourths of a dram of crystals of tartar, which last are previously boiled in the water till dissolved; or with two drams of fresh lemon peel, and two drams by measure of lemon juice. The committee of the London college observe, that this last is the most agreeable form they have been able to contrive, for the exhibition of sena to those who are more than ordinarily offended with its flavour; and that though acids are generally supposed to impede the action of water on vegetables, yet the infusions of sena made with acids are found, from experience, not to fail in their intention. Indeed, if the acids really weaken the dissolving power of the water, which it is probable they do in some degree, they should seem to be, on this account, rather of advantage than otherwise; for, as the committee further observe, in a medicine very nauseous to many, it is of primary consequence that only the lighter and least disgustful parts be extracted. On this principle, some macerate the sena for a night in cold water, which becomes sufficiently impregnated with its purgative virtue, without extracting so much, as boiling water does, of the nauseous matter: if the liquor, poured off from the sena, be boiled a little by itself, great part of its ill flavour will be dissipated; and the remains of its offensiveness may be effectually covered by infusing in it some Bohea tea. If the coction is continued for any considerable time, the purgative virtue of the sena will be diminished; for the inspissated watery extracts are scarcely found to purge so much, as one fourth of the infusion or decoction they were made from, or so much as an equal weight of the leaves in substance.

The officinal spirituous tinctures of sena are prepared by digestion for some days with or without heat, in proof spirit. The proportions, in the London Pharmacopœia, are, one dram of sena to an ounce and a quarter of the spirit, to which are added a dram and a quarter of stoned raisins, seven grains and a half of caraway seeds, and two grains and a half of lesser cardamom seeds husked: in the Edinburgh, half a dram of sena to an ounce and a half of the spirit, with the addition of fifteen grains of rhubarb, seven grains and a half of shavings of guaiacum, the same quantity of sweet fennel seeds, the same of juniper berries, and forty-five grains of white sugar-candy in powder, which last is directed to be dissolved in the tincture, after straining it from the other ingredients. Both these tinctures are agreeable and useful carminative purgatives, especially to those who have accustomed themselves to spirituous liquors; the ill flavour of the sena is completely covered, and its offending the stomach or producing gripes prevented, by the warm seeds and the sweets. The guaiacum, in the second prescription, promotes the operation of the sena; for two drams of sena, infused in half a pint of a decoction of guaiacum, purge as briskly as three drams infused in plain water, and with greater ease to the patient. Several compositions of this kind have been offered to the public, under the name of Daffy's Elixir: the two above are inferior to none, and superior to most of them.

SENATE, an assembly, or council of senators; that is, of the principal members of a state, who have a share in the government.

SENATOR, a member of a senate.

SENATUS-CONSULTUM, a vote or resolution of the Roman senate, with regard to some question or litigated

gated point, and which resolution then became a part of the Roman law.

SENDING, in the sea language, the act of pitching or plunging headlong with the ship's fore part. See PITCHING.

SENGREEN, in botany, the same with *Sempervivum*. See the article *SEMPERVIVUM*.

SENNA. See *SENA*.

SENNAT, among sailors, a sort of braided cordage formed by the platting of five, seven, or nine rope yarns into one another; it is employed for various uses in a ship, particularly to form netting, &c. See the article *NETTING*.

SENSATION, the act of perceiving external objects, by means of the organs of sense.

To conceive the manner wherein sensation is affected, observe, that all the organs consist of little filaments, or nerves, which have their origin in the middle of the brain, are diffused thence throughout all the members which have any sense, and terminate in the exterior parts of the body; that when we are in health, and awake, one end of these nerves cannot be agitated or shaken, without shaking the other, by reason they are always a little stretched; as in the case of an extended chord, one part of which cannot be stirred without a like motion of all the rest.

It is to be likewise observed, that these nerves may be agitated two ways, either at the end out of the brain, or that in the brain. If they be agitated from without, by the action of objects, and their agitation be not communicated as far as the brain; as frequently happens in sleep, when the nerves are in a state of relaxation; the soul does not then receive any new sensation. But if the nerves happen to be agitated in the brain, by the flux of the animal spirits, or any other cause; the soul perceives something, though the parts of those nerves, that are out of the brain, diffused through the several parts of the body, remain at perfect rest: as likewise is frequently the case in sleep.

Lastly, observe, that experience tells us, we may sometimes feel pain in parts of the body that have been entirely cut off, by reason of the fibres in the brain corresponding to them being agitated in the same manner as if they were really hurt; the soul feels a real pain in those imaginary parts.

All these things seem to shew, that the soul resides immediately in that part of the brain wherein the nerves of all the organs of sense terminate: we mean, it is there it perceives all the changes that happen with regard to the objects that cause them, or that have been used to cause them; and that it only perceives what passes out of this part, by the mediation of the fibres terminating in it.

These things premised, it will not be difficult to explain how sensation is performed: the manner of which may be conceived from what follows. When the point of a needle, for instance, is thrust against the hand, that point stirs and separates the fibres of the flesh, which fibres are extended from that place to the brain, and when we are awake, are in such a degree of tension, as that they cannot be stirred without shaking those of the brain. If then the motion of the fibres of the hand be gentle, that of the fibres of the brain will be so too; and, if the first be violent enough to break any thing in the hand, the last will be stronger and more violent in proportion. In like manner, if the hand be held to the fire, the little particles of the wood it throws off in great numbers, and with a great deal of violence, striking against these fibres, and communicating a part of their agitation thereto; if the action be moderate, that of the extremities of the fibres of the brain, corresponding to those of the hand, will be moderate likewise: if it be violent enough to separate any of the parts of the hand, as it happens in burning; the motion of the fibres in the brain will be proportionably more violent. This is what befalls the body, when objects strike upon it. We are now to consider how the mind is affected.

The mind, we have observed, resides principally, if we may be allowed to say so, in that part of the brain where all the fibres of the nerves terminate. It attends here, as its sensory, or office, to look to the preservation of all the parts of the body; and, of consequence, must

be here advertised of all the changes that happen, and must be able to distinguish between those agreeable to the constitution of the body, and those hurtful thereto. Any other absolute knowledge, without a relation to the body, were useless. Thus, though all the changes in our fibres do, in reality, consist in motions, which ordinarily only differ as to more and less; it is necessary the soul should consider them as changes essentially different; for, though in themselves they differ but very little, yet, with regard to preservation of the body, they are to be looked on as essentially different.

The motion, for instance, which causes pain, frequently differs exceeding little from that which occasions a pleasing titillation: it is not necessary there should be an essential difference between these two motions; but it is necessary there be an essential difference between the pain and the tickling, which those two motions occasion in the soul; for the agitation of the fibres, which accompanies the titillation, informs the soul of the good state of the body, that it is able to resist the impression of the objects, and that it need not apprehend its being hurt: but the motion which occasions pain, being somewhat more violent, is capable of breaking some of the fibres of the body; wherefore it is necessary the soul be advertised hereof by some disagreeable sensation, that it may provide against it.

Thus, though all the motions which pass in the body only differ in themselves, as to more or less, yet, when considered with regard to the preservation of life, they may be said to be essentially different: for this reason it is, that the soul does not perceive the shakes, or motions themselves, which objects excite in the fibres of the flesh: it would be useless to perceive them; and she would never be able, thence, to learn whether the objects were capable of doing hurt or good. But she perceives herself affected with sensations, which differ essentially, and which shewing precisely the qualities of the objects, as they regard the body, make her perceive distinctly, whether or no those objects are capable of hurting it.

In effect, from a strict examination of the several senses, it appears, that sensible objects act no otherwise upon the body, for the producing of sensation, than by exciting a change in the extreme surface of the fibres of the nerves: the quality of which change depends on the figure, bulk, hardness, and motion of the object; so that, according to all appearance, the most different objects, which should agree in these four circumstances, would produce the same sensation.

From the various texture of the object, the diversity of the nerve affected, the different fabric of the organ of sense, the different place in the medulla of the brain where the nerve arises, and the different degree of motion wherewith the action of the object is applied, cause various sensations and ideas in the mind; none of which represent any thing in the action of the object, or in the passion of the organ. And yet the same action of the same object on the same organ, always produces the same sensation or idea: and the same ideas necessarily follow the same disposition of the same sensible organ, in the same manner as if the idea perceived were the natural and necessary effect of the action on the organ.

SENSE, a faculty of the soul whereby it perceives external objects, by means of some impression made in the organs of sense.

Some use the word sense in a greater latitude; and define it a faculty whereby the soul perceives ideas or images of objects, either conveyed to it from without, by the impression of objects themselves, or excited within by some effort of the soul of the sensory itself.

Under which notion, sense becomes distinguishable into two kinds, external and internal: corresponding to the two several manners wherein the images of the objects perceived are occasioned, and presented to the mind, viz. either immediately from without, or from within; that is, either by what we commonly call the five external senses, hearing, seeing, &c. or by the internal ones, imagination, memory, and attention; to which some add hunger and thirst.

But these internal senses are not ordinarily considered in the notion of senses, nor implied under the word sense; but are thus only denominated by analogy.

The means, on the part of the mind, are always the same; it being one and the same faculty, whereby we see, hear, &c.—The means on the part of the body, are different; as different as are the objects we are concerned to perceive: for, the being and well-being of the animal being the end nature had in view in giving him any perception of external bodies, by this, the measure and manner of that perception is regulated: and we have so many ways of perceiving, and of perceiving so many things, as the relation we bear to external bodies renders necessary for the preservation, &c. of our being.

Hence those several organs of sense, called eye, ear, nose, palate, and the universal one cutis; each of which is so disposed as to give some representation and report to the mind of the state of external things, the nearness, convenience, hurtfulness, and other habitudes; and each of them a different one, according to the degree, and immediateness, &c. of the danger, or convenience. And hence the several exercises of those organs, hearing, seeing, smelling, tasting, and feeling.

A late excellent author gives us a more ingenious, extensive, and philosophical notion of sense.—On his principle, sense is defined a power of perception, or a power of receiving ideas; if what is absolutely passive may be properly called a power.

On some occasions, instead of power, he chuses to call it a determination of the mind to receive ideas.—The ideas thus perceived, or raised in the mind, he calls sensations. Sense he considers, either as natural or moral: and the natural, either as external or internal; tho' the distribution is chiefly founded on the common ways of conceiving; for, in reality, they appear to be all natural and necessary: some reasons, however, for the distinction, will be shewn under the several articles thereof.

External SENSES, the means whereby the soul takes cognizance of external objects. They are commonly reckoned five in number, viz. the eye, ear, nose, palate, and cutis, or skin.

External senses, then, are powers of perceiving ideas, upon the presence of external objects.—On such occasions, we find the mind is merely passive, and has not power directly to prevent the perception, or idea, or to vary it at its reception; as long as the body is continued in a state fit to be acted upon by the external object.

When two perceptions are intirely different from each other, or agree in nothing but the general idea of sensation; the power of receiving those different perceptions is called different senses. Thus seeing and hearing denote the different powers of receiving the ideas of colours and sounds. And though colours, as well as sounds, have vast differences amongst themselves; yet is there a greater agreement among the most opposite colours, than between any colour and a sound; and hence all colours are deemed perceptions of the same sense.

All the several senses seem to have their distinct organs, except feeling, which is, in some degree, diffused over the whole body.

Internal SENSES, are powers or determinations of the mind to be pleased with certain forms and ideas, which occur to our observation in objects perceived by the external senses.

Of these there are two different species, distinguished by the different objects of pleasure, viz. pleasurable or beautiful forms of natural things, and pleasurable or beautiful actions, or characters of rational agents: whence the internal senses become divisible into natural and moral; though what we call the internal natural sense, our author call simply, and by way of eminence, the internal sense.

In reflecting on our external senses, we plainly see, that our perceptions of pleasure, and pain, do not depend directly on our will. Objects do not please us according as we incline they should; the presence of some objects necessarily pleases us, and the presence of others as necessarily displeases us; nor can we, by our will, any otherwise procure pleasure, or avoid pain, than by procuring the former kind of objects, and avoiding the latter. By the very frame of our nature, the one is made the occa-

sion of delight, and the other of dissatisfaction. In effect, our sensitive perceptions are pleasant and painful, immediately, and without any knowledge of the cause of this pleasure and pain, or of the manner how they excite it, or are occasions of it, or without seeing to what further advantage, or detriment, the use of such objects might tend. Nor would the most accurate knowledge of these things vary either the pleasure, or the pain, of the perception; however it might give a rational pleasure distinct from the sensible; or might raise a distinct joy, from prospect of further advantage in the object, or aversion, from apprehension of evil. There is scarce any object, which our minds are employed about, but is constituted the necessary occasion of some pleasure or pain. Thus we shall find ourselves pleased with a regular form, a piece of architecture or painting, a composition of notes, a theorem, an action, an affection, a character; and we are conscious that this pleasure naturally arises from the contemplation of the idea then present in the mind, with all its circumstances, though some of those ideas have nothing of what we call sensible perception in them; and, in those which have, the pleasure arises from some uniformity, order, arrangement, imitation; and not from the simple ideas of colour, or sound, or mode of extension separately considered.

It seems hence to follow, that, when instruction, education, or prejudice of any kind, raise any desire or aversion towards an object, this desire, or aversion, is founded on an opinion of some perfection, or deficiency, in those qualities, for perception whereof we have the proper senses. Thus, if beauty be desired by one who has not the sense of sight; the desire must be raised by some apprehended regularity of figure, sweetness of voice, smoothness, softness, or some other quality perceivable by the other senses, without relation to the ideas of colour.

The only pleasure of sense, which our philosophers seem to consider, is that which accompanies the simple ideas of sensation; but there are vastly greater pleasures in those complex ideas of objects, which obtain the names of beautiful and harmonious.—The power, then, whereby we receive ideas of beauty and harmony, has all the characters of a sense. It is no matter, whether we call these ideas of beauty and harmony perceptions of the external senses of seeing and hearing, or not: we should rather chuse to call these ideas an internal sense, were it only for the convenience of distinguishing them from other sensations of seeing and hearing, which men may have without perception of beauty and harmony.

Moral SENSE, a determination of the mind, to be pleased with the contemplation of those affections, actions, or characters of rational agents, which we call good or virtuous.

This moral sense of beauty, in actions and affections, may appear strange at first view: some of our moralists themselves are offended at it in my lord Shaftsbury, as being accustomed to deduce every approbation, or aversion, from rational views of interest. Our gentlemen of good taste can tell us of a great many senses, tastes and relishes for beauty, harmony, imitation in painting and poetry; and may we not find, too, in mankind, a relish for a beauty in characters, in manners? The truth is, human nature does not seem to have been left quite indifferent, in the affair of virtue, to form to itself observations concerning the advantage or disadvantage of actions, and accordingly to regulate its conduct. The weakness of our reason, and the avocations arising from the infirmity and necessities of our nature, are so great, that very few of mankind could have framed those long deductions of reason, which may shew some actions to be, in the whole, advantageous, and their contraries pernicious. The Author of nature has much better furnished us for a virtuous conduct, than our moralists seem to imagine, by almost as quick and powerful instructions, as we have for the preservation of our bodies; he has made virtue a lovely form, to excite our pursuit of it, and has given us strong affections, to be the springs of each virtuous action.

SENSITIVE SOUL, a denomination given to the souls of brutes, or that which man is by some supposed to have in common with brutes.

SENSITIVE PLANT, in botany, a plant whose frame and constitution is so nice and tender, that on the touch or least pressure of the hand it will contract its leaves, as if sensible of the touch.

The structure of the sensitive plant is this: from the large stems, or main branches of the whole, there part off several other lesser ones, and from these there go off others still less, which, by way of distinction, may be called the ribs of the leaves, as they serve to support a number of leaves arranged on each side, and standing on short pedicles in pairs over-against one another. Several other plants have this sort of compound leaves, as the cassia, colutea, and the like; and all these shut their leaves together at night, and open them again in the morning, in the same manner as the sensitive plant does. This periodical opening and shutting of the leaves is therefore common to many plants, not peculiar to the sensitive plant; but the wonder in this is, that, besides having this motion periodical and regular, it is to be brought on at other times, and by accidents, there requiring no more than the touching the plant to make it close its leaves at any time of the day, which it soon afterwards naturally opens again. This is peculiar to this plant, and resembles the action of an animal which had been injured or frightened. A close observation also of the manner in which this is performed, will give many hints towards the finding its cause.

It is a very difficult thing to touch the leaf of a vigorous sensitive plant so lightly as not to make it close. Its sensation is extremely delicate; and its large rib or nerve, which runs along its middle, is as it were a hinge, on which the two halves of the leaf move, when they turn upon being touched, till they stand erect, and by that means meet one another.

The slightest touch imaginable gives this motion to the side of the leaf which is touched, which is communicated immediately to the other side or half, and they move together; and, if the touch hath been a very little rougher, the opposite leaf on the same rib receives the impression, and closes up in the same manner with that which was actually touched.

Nor is this all: for, when the two sides of each of these leaves move upwards, the pedicle of each half moves upwards at the same time, and by this means they, in some measure, approach towards each other, and make the angles of their pedicles with the main rib, or stalk, of the composite leaf, less than before; and the total motion of each leaf is composed of these two motions.

If the touch be still rougher, the whole arrangement of leaves on the same rib feel its influence on each side, and all close in the same manner with the single pair in the preceding instance; and, if the touch be yet stronger than this, the rib itself feels it, and attempts to close in its way, moving itself upwards towards the branch from which it is produced, just as the single pedicles of the leaves did towards it; and, if the touch be yet more hard and rough, the very branches have the sensation propagated to them, and apply themselves to the main stem or trunk of the shrub, as the simple leaves did before to their rib, and that rib to the branch: so that the whole plant in this state forms itself, from a very complexly-branched figure, into a sort of straight cylindric one. The motion which has, of all others, the greatest effect upon this plant, is a shaking one.

These three motions of the plant are performed by means of three distinct and sensible articulations; the first, that of the single leaf to its pedicle; the second, that of the pedicle to its branch; the third, that of the branch to the trunk. The primary motion of all which is the closing of the two halves of the leaf upon this rib, which ought also to be performed in a similar manner, and by a similar articulation; this, however, is much less visible than the others.

These motions are wholly independent on one another, as may be proved by experiment. It should appear, that, if the stalks are moved and collapse towards the branches, or these towards the trunk, that the leaves, whose motion is usually primary to these, should be affected also; yet experiment proves, that it is possible to touch the branches in such a manner, as to affect them only, and make them apply themselves to the

trunk, while the leaves feel nothing of the touch: but this cannot be, unless the branches are so disposed, as that they can fall to the trunk without suffering their leaves to touch any other part of the plant in their passage; because, if they do, they immediately become affected. Winds and heavy rains cause the sensitive plants to shut up their leaves, while easy showers do not at all affect them: it is plain from hence, that the agitation of the plant by the wind, and the strokes given by the large and hasty drops of rain, are what cause the contraction.

By whatever accident the plant has been made to close its leaves, it always regularly opens them again afterwards. This, however, requires different times, according to several circumstances, as the time of the day, the season of the year, and the more or less vigorous and healthy state of the plant: sometimes this is done in ten minutes, sometimes it requires half an hour. And the manner is not less different than the time: for sometimes the leaves unfold themselves first, and sometimes the branches; whereas sometimes all is done at once, and the whole plant seems in motion at a time.

In endeavouring to account for the motions of this plant, Mess. Du Fay and Du Hamel have conjectured, that they are performed by means of a sort of very nice and fine hinges, which communicate one with another by means of very minute and slender cords, which occasion them to act as we see when the plant is sufficiently disturbed, and these cords shaken; and what gives a strong probability to this conjecture is, that the decayed and dying leaves of this plant perform this motion as regularly and vigorously, as those which are fresh and full of juice. It seems plain, that, while the juices are evaporating, and the parenchymatous substance of the leaves drying up, these more solid parts, the lines and cordages, retain their figure; and, consequently, if it is, by means of these, that the motion is always performed, it will be as well performed in these as in the fresher leaves; which could not be the case, were it owing to the juices.

The natural opening and shutting of the leaves of this plant, at night and morning, are not so fixed but that they are variable also, according to circumstances of place, temperature, &c. In the month of August, a sensitive plant was carried in a pot out of its usual place into a dark cave; the motion that it received in the carriage shut up its leaves, and they did not open for twenty-four hours afterwards. At this time they became moderately open, but afterwards subject to no changes at night or morning, but remained three days and nights with their leaves in the same moderately open state. At the end of this time they were brought out again into the air, and there recovered their natural periodical motions, shutting every night, and opening every morning, as naturally and as strongly as if it had not been in this forced state; and, while in the cave, it was observed to be very little less affected with the touch, than when abroad in the open air.

Repeated experiments have proved, that it is not the light of the day that opens these plants, nor the darkness of the night that closes them; neither is it the alternate warmth of the day, and cold of the night, that have this effect, since it shuts in nights that are much warmer than the days often are, in which it opens; and the increasing the heat of the place in which it is kept, and marking the increase or decrease on the thermometer, have not been found to have the least effect, as to its sooner or later opening or shutting its leaves.

The most probable conjecture seems, that it is not great heat, or great cold, such as it can bear, that brings on this effect, but the sudden change from one to the other; and this is confirmed by this experiment: that, if one of these plants be raised under a glass bell or case, and the bell or covering be taken off, it immediately closes, even though it be in the middle of the day; and this is also observed, that, the more open or exposed the plant stands, the more strong and lively are its shutting and opening; and that they are most observable in summer, and much less so, when it is kept in a close stove in winter.

The great heats of summer, when there is open sunshine at noon, affect the plant in some degree like cold, causing it to shut up its leaves a little, but never in any great

great degree. The plant, however, is least of all affected about nine o'clock in the morning, and that is, consequently, the properest time to make experiments on it. A branch of the sensitive plant, cut off and laid by, retains yet its property of shutting and opening in the morning for some days; and it holds it longer, if kept with one end in water, than if left to dry more suddenly.

The leaves only of the sensitive plant shut up in the night, not the branches; and, if it be touched at this time, the branches are affected in the same manner as in the day, shutting up, or approaching to the stalk or trunk, in the same manner, and often with more force. It is of no consequence what the substance is with which the plant is touched, it answers alike to all; but there may be observed a little spot, distinguishable by its paler colour in the articulations of its leaves, where the greatest and nicest sensibility is evidently placed.

SENSORY, *Sensorium commune*, the seat of the common sense, or what receives the impressions of all sensible objects, conveyed to it by the nerves of each particular organ, and consequently is the immediate cause of perception. This office is by Dr. Willis, attributed to the striated part of the brain, and by Des Cartes to the glandula pinealis.

SENTENCE, in law, a judgment passed in court by the judge on some process, either civil or criminal.

SENTENCE, in grammar, a period or set of words comprehending some perfect sense or sentiment of the mind.

SENTENCE, in poetry, is an instructive and lively remark made on something very observable, and agreeably surprising, which contains much sense in few words.

SENTIMENTS, in poetry, and especially dramatic, are the thoughts which the several persons express, whether they relate to matters of opinion, passion, business, or the like.

SENTINEL, **CENTINEL**, or **CENTRY**, in military affairs, is a private soldier placed in some post to watch any approach of the enemy, to prevent surprizes, and to stop such as would pass without order, or discovering who they are.

SEPARATING GLASS, in chemistry, a receiver having a spout at the bottom, for separating oil from water, in distillation. See the article **CHEMICAL LABORATORY** (plate XXXIX. fig. 33.).

SEPARATISTS, an appellation given to dissenters, from their setting up a separate church from the established one.

SEPTEMBER, the seventh month of the year, reckoning from the vernal equinox, or the ninth from January.

SEPTENTRIO, in astronomy, a constellation more usually called *ursa minor*. See **URSA**.

SEPTICS, among physicians, an appellation given to all such substances as promote putrefaction.

From the many curious experiments made by Dr. Pringle to ascertain the septic and antiseptic virtue of natural bodies, it appears that there are very few substances of a truly septic nature. Those commonly reputed such by authors, as the alkaline and volatile salts, he found to be no wise septic. However, he discovered some, where it seemed least likely to find any such quality; these were chalk, common salt, and the testaceous powders. He mixed twenty grains of crabs eyes, prepared with six drams of ox's gall, and an equal quantity of water. In another phial he put an equal quantity of gall and water, but no crabs-eyes. Both these mixtures being placed in the furnace, the putrefaction began much sooner where the powder was, than in the other phial. On making a like experiment with chalk, its septic virtue was found to be much greater than that of the crabs-eyes: nay, what the doctor had never met with before, in a mixture of two drams of flesh with two ounces of water and thirty grains of prepared chalk, the flesh was resolved into a perfect mucus in a few days.

To try whether the testaceous powders would also dissolve vegetable substances, the doctor mixed them with barley and water, and compared this mixture with another of barley and water alone. After long maceration by fire, the plain water was found to swell the barley, and turn

mucilaginous and sour; but that with the powder kept the grain to its natural size, and though it softened it, yet made no mucilage and remained sweet.

Nothing could be more unexpected, than to find sea-salt a hastener of putrefaction, but the fact is thus: one dram of salt preserves two drams of fresh beef in two ounces of water, above thirty hours, uncorrupted, in a heat equal to that of the human body; or, which is the same thing, this quantity of salt keeps flesh sweet twenty hours longer than pure water. But then half a dram of salt does not preserve it above two hours longer. Twenty-five grains have little or no antiseptic virtue, and ten, fifteen, or even twenty grains manifestly both hasten and heighten the corruption. The quantity, which had the most putrefying quality, was found to be about ten grains to the above proportion of flesh and water.

Many inferences might be drawn from this experiment. One is, that since salt is never taken in aliment beyond the proportion of the corrupting quantities, it would appear that it is subservient to digestion, chiefly by its septic virtue, that is, by softening and resolving meats: an action very different from what is commonly believed.

It is to be observed that the above experiments were made with the salt kept for domestic uses. *Pringle's Observ. on Dis. of the Army.*

SEPTUAGESIMA, in the calendar, the third Sunday before Lent.

The word is formed from the Latin, *septuaginta*, seventy; because about seventy days before Easter.

SEPTUAGINT, **LXX**, or *The Seventy*, the name of a famous version of the Old Testament, out of Hebrew into Greek, performed by seventy-two Jewish interpreters, in obedience to an order of Ptolemy Philadelphus.

This version was in use at the time of our Blessed Saviour, and is that out of which all the citations in the New Testament, from the original Greek of the Old, are taken. It was the ordinary and canonical translation made use of by the Christian church in the earliest ages; and it still subsists in the churches both of the East and West. The history of this version is expressly written by Aristæus, an officer of the guards to Ptolemy Philadelphus. The substance of this author's account of the Septuagint is as follows.

Ptolemy having erected a very fine library at Alexandria, took care to fill it with the most curious and valuable books from all parts of the world. Being informed, that the Jews had one, containing the laws of Moses, and the history of that people, he formed the design of getting it translated out of Hebrew into Greek, to enrich his library therewith. To this purpose it was necessary to apply to the high-priest of the nation: but this was attended with a great difficulty. There was in Egypt a great number of Jews reduced to slavery by his father Ptolemy Soter, in the invasions he had made into Judea. It was represented to the king, that it was in vain to expect from the Jews a copy, or a faithful translation of their law, whilst he detained so great a number of their countrymen in servitude. Ptolemy, who was extremely generous, and had very much at heart the improvement of his library, immediately set at liberty all the Jews in his dominions. After such a step, he easily obtained what he desired of the Jewish high-priest, named Eleazar, who sent back his ambassadors with an exact copy of the Mosiacal law written in letters of gold, and six elders of each tribe, in all seventy-two, to translate it into Greek. These deputies were received with all the marks of respect by the king, and then conducted into the isle of Pharos, and lodged in a house prepared for their reception, where they were supplied with every thing necessary in abundance. They set about the translation without loss of time, and finished it in seventy-two days. The whole was read, and approved, in the presence of the king, who admired the profound wisdom of the laws of Moses, and sent back the deputies laden with presents for themselves, the high-priest, and the temple.

The historian has added many other circumstances, which, because they appear to be less probable, we shall omit. But it must not be dissembled, that this work of Aristæus is thought by many learned men to be spurious; and that

that the writers, whether Jews, as Aristobulus, Philo, and Josephus; or Christians, as Justin Martyr, Clements Alexandrinus, Irenæus, Hilary, Augustin, and some others, who have reported the fact of the version of the Septuagint; have done it upon the single authority of Aristæas. Some of these writers have added circumstances which are too marvellous to deserve any credit. Thus Philo tells us, that each of them translated the whole Bible separately, and yet there was not the minutest difference either in sense or expression, between their several translations; whence he concludes, that they were all directed by the spirit of God. And Justin Martyr, and the other fathers, assure us, that they worked in separate cells, and had no communication with each other; notwithstanding which, their translations were found to be exactly uniform and agreeable to each other. The reader may consult the learned Dr. Prideaux, who has fully treated of this subject. What is certain is, that there was a Greek translation of the Scriptures made in Egypt, in the time of the Ptolemies, and that this very version is extant among us under the title of the Septuagint.

Philo tells us, that the Jews of Egypt were so transported upon the making this translation of the Scriptures into Greek; that they kept an annual feast in memory of it; at which time they went into the isle of Pharos, and performed their devotions, out of respect to a place, which had been sanctified by the presence of the seventy interpreters. On the contrary, the Jews of Palestine conceived so much contempt and abhorrence for this version, that they fasted on the eighth day of Thebet, to shew how much they disapproved the liberty that had been taken in translating the law into a foreign and impure language.

We shall subjoin M. Rollin's reflection on this translation of the Bible into Greek. "This version, which made the scriptures intelligible to an infinite number of people, was one of the most considerable fruits of the Grecian conquests: and it appears plainly to have been a part of the principal design, which God had in delivering all the East into the hands of the Greeks, and supporting them therein, notwithstanding the divisions, jealousies, battles, and the frequent revolutions that happened among them. God by this means prepared an easy way for the preaching of the gospel, which was near at hand, and more readily united so many nations, different both in language and manners, in one society, in the same worship, and in the same doctrine, by one language, the most elegant, copious, and correct, that was in the world, and which became common to all the countries conquered by Alexander."

Chronology of the SEPTUAGINT, is an account of the years of the world, very different from what is found in the Hebrew text and the Vulgate, making the world 1466 years older than these latter.

SEPTUM, a Latin word, literally signifying a partition or inclosure, and, in anatomy, is applied to several parts of the body, which serve to separate one part from another.

SEPULCHRAL, something belonging to the sepulchres, or tombs.

SEPULCHRE, a tomb or place destined for the interment of the dead. It is chiefly used in speaking of the burying-places of the antients; those of the moderns are usually called tombs.

Regular Canons of St. SEPULCHRE, a religious order, formerly instituted at Jerusalem, in honour of the holy sepulchre, or the tomb of Jesus Christ.

Knights of the holy SEPULCHRE, a military order, established in Palestine about the year 1114.

SEQUEL, in logic, a consequence drawn from some preceding proposition.

SEQUESTRATION, in common law, the act of separating a thing in controversy from the possession of both parties, till the right be determined by course of law.

SEQUIN, ZECHIN, or ZECCHINO, a gold coin struck at Venice, and several parts of the grand seignior's dominions, particularly at Cairo. The value of these sequins is different, those of Venice exceeding those of Turkey by nearly one fifteenth part.

SERAGLIO, among the Orientals, the palace of a prince or lord, but it is used by way of excellence for the palace of the grand seignior at Constantinople.

SERAPH, or SERAPHIM, in theology, a spirit of the first or highest rank.

The word is formed from the Hebrew שרף, to burn, or inflame; because they are supposed to be most inflamed with divine love.

SERAPHIC, burning or inflamed with love or zeal, like a seraphim: thus St. Bonaventure is called the seraphic doctor, from his abundant zeal and fervor.

SERENADE, a kind of concert given in the night, by a lover to his mistress, under her window.

SERENE, a quality or title of honour given to certain princes and chief magistrates of republics.

SERGE, in commerce, a woollen stuff manufactured in the loom, the warp of which is composed of the longest, and the woof of the shortest wool.

SERGEANT *at Law*, or of the *coif*, is the highest degree taken in the common law, as that of doctor is in the civil law.

SERGEANT *at Arms*, is an officer appointed to attend the person of a king, arrest traitors and persons of quality offending, and to attend the lord steward when he sits in judgment on any traitor.

SERGEANT, or SERJEANT, in the army, is an inferior officer in a company of foot, or troop of dragoons; armed with a halberd, and appointed to see discipline observed, to teach the soldiers the exercise of their arms, to see due distance kept, to form ranks, files, &c.

SERGEANTRY, or SERJEANTRY, in law, is taken for a service that cannot be due from a tenant to any other lord besides the king.

SERJANIA, a name given to a genus of plants by father Plumier, who discovered them in America, in honour to the reverend father Philip Serjeant, who was of the order of the Minims, and a person well versed in the knowledge of botany and physics.

The characters of the genus are: it hath a rose-shaped flower, consisting of four or more leaves, which are placed in a circular order: from whose flower-cup arises the pointal, which afterwards becomes a fruit composed of three cells having three wings, and each cell containing one round seed.

SERIES, a continued succession of things in the same order, and which have some relation to, or connection with each other.

SERIES, in algebra, a rank or progression of quantities, increasing or decreasing in some constant ratio: which, in its progress, approaching still nearer and nearer some sought value, is called a converging series, and, if infinitely continued, becomes equal to that quantity; whence the usual appellation infinite series. See PROGRESSION.

The method of series took its rise from the learned Dr. Wallis's arithmetic of infinites, and has of late been so pursued by the greatest mathematicians, that it is now one of the greatest improvements in algebra.

Nature and Use of infinite SERIES. — Though arithmetic furnishes us with very adequate and intelligent expressions for all rational numbers, yet it is very defective as to irrational ones, which are infinitely more numerous than the other; there being, for instance, an infinity of them between one and two, were it now required to find a mean proportional between 1 and 2, in rational numbers which alone are clearly intelligible (the root of 2 being certainly a very obscure idea) we could still approach nearer and nearer to the just value of the quantity required, but without ever arriving at it: thus, if for the mean proportional between 1 and 2, or the root of 2, we first put 1, it is evident we have not put enough; if we add $\frac{1}{2}$, we put too much, for the square of $1 + \frac{1}{2}$ is greater than two. If then we take away $\frac{1}{4}$, we shall find we have taken away too much, and if we return $\frac{1}{8}$, the whole will be too great: thus may we proceed, without ever coming at the just quantity sought. — These numbers thus found, and those found after the same manner to infinity, being disposed in their natural order, make what we call an infinite series.

Sometimes the series's do not proceed by alternate additions and subtractions, but by simple additions, or an in-

Infinity of subtractions, according to the position of the first term. In all these infinite series's it is visible, that, as all the terms are only equal to a finite magnitude, they must be still decreasing; and it is even convenient that they be so, as much as possible, that one may take only a certain number of the first terms for the magnitude sought, and neglect all the rest.

But it is not irrational numbers only, that are expressed in rational ones, by infinite series's. Rational numbers themselves may be expressed in the same manner: 1, for instance, being equal to the series $\frac{1}{2} + \frac{1}{4} + \frac{1}{8}$, &c. but there is this difference between them, that whereas irrational numbers can only be expressed in rational numbers, by such series; rational ones need no such expression.

Among infinite series's, there are some whose terms only make a finite sum: such is the geometrical progression $\frac{1}{2} + \frac{1}{4} + \frac{1}{8}$, &c. and in general, all geometrical decreasing progressions: in others, the terms make an infinite sum; such is the harmonical progression $\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5}$, &c. See HARMONICAL. It is not that there are more terms in the harmonical, than in the geometrical progression, though the latter has no term which is not in the former, and wants several the former has; such a difference would only render the two infinite sums unequal, and that of the harmonical progression the greatest: the cause lies deeper.

From the received notion of infinite divisibility, it follows, that any finite thing, e. gr. a foot, is a compound both of finite and infinite: finite, as it is a foot: infinite as it contains an infinity of parts, into which it is divisible. If these infinite parts be conceived, as separated from one another, they will make an infinite series, and yet their sum only be a foot: only, no terms are to be here put, but such as may, distinct from each other, be parts of the same finite whole: now this is the case in the geometrical decreasing series $\frac{1}{2} + \frac{1}{4} + \frac{1}{8}$, &c. for it is evident, that, if you first take $\frac{1}{2}$ of a foot, then $\frac{1}{4}$ of what remains, or $\frac{1}{8}$ of a foot, then $\frac{1}{16}$ of what remains, or $\frac{1}{32}$ of a foot; you may proceed to infinity, still taking new decreasing halves, all distinct from each other, and which all together only make a foot.

In this example, we not only take no parts but what were, in the whole, distinct from each other; but we take all that were there; whence it comes to pass, that their sum makes the precise whole again; but were we to follow the geometrical progression $\frac{1}{3} + \frac{1}{9} + \frac{1}{27}$, &c. that is, at first take $\frac{1}{3}$ of a foot, and from what remains $\frac{1}{9}$ of a foot, and from what still remains $\frac{1}{27}$ of a foot, &c. it is true, we should take no parts but what were distinct from each other in the foot; but we should not take all the parts that were there, since we only take the several thirds, which are less than the halves; of consequence, all these decreasing thirds, tho' infinite in number, could not make the whole; and it is even demonstrated, that they would only make half. In like manner, all the fourths, decreasing to infinity, would only make one third, and all the hundredths, only the ninety-ninth part: so that the sum of the terms of an infinite series, decreasing geometrically, is not only always finite, but may even be less than any finite quantity that can be assigned.

If an infinite decreasing series expresses parts which cannot subsist in the whole, distinctly from each other; but such as, to take their values, we must suppose the same quantity taken several times, in the same whole; then will the sum of these parts make more than a whole, nay, infinitely more; that is, the series will be infinite, if the same quantity be taken an infinity of times. — Thus, in the harmonical progression $\frac{1}{2} + \frac{1}{3} + \frac{1}{4}$, &c. if we take $\frac{1}{2}$ of a foot, or 6 inches, then $\frac{1}{3}$ 4 inches, it is evident we cannot take further $\frac{1}{4}$ of a foot, or 3 inches, without taking 1 inch more than was left in the foot. Since then the whole is already exhausted by the three first terms, we can take no more of the following terms, without taking something already taken: and, since those terms are infinite in number, it is very possible that the same finite quantity may be repeated an infinite number of times, which will make the sum of the series infinite.

We say possible; for though of two infinite series's the one may make a finite sum, and the other an infinite; it is true that there may be such a series, where, the finites having exhausted the whole, the following ones,

though infinite in number, shall only make a finite sum; and, in effect, since it is demonstrated, by the laws of geometrical progression, that there are series's, whose sums are less than the whole, nay, infinitely less, it follows, that there must likewise be series's which make infinitely more.

There are two further remarks necessary to be made on series's in general. 1. That there are some, wherein, after a certain number of terms, all the other terms, though infinite in number, become each a cypher. Now it is evident, the sum of these series's is finite, and easily found; they having only an appearance of infinity.

2°. That the same magnitude may be expressed by different series's; and may be expressed both by a series, whose sum may be found, and by another, whose sum cannot be found.

Geometry does not labour under the same difficulty as arithmetic: it expresses irrational numbers exactly in lines, and needs not have recourse to infinite series's. Thus the diagonal of a square, whose side is 1, is known to be the square root of 2. — But, in some other cases, geometry itself is under the like embarrass; there being some right lines, which cannot be expressed otherwise than by an infinite series of smaller lines, whose sum cannot be found: of which kind are the right lines equal to curves; so that in seeking, for instance, a right line equal to the circumference of a circle, we find, that, the diameter being 1, the line sought will be $\frac{1}{2}$, minus $\frac{1}{8}$, plus $\frac{1}{16}$, minus $\frac{1}{32}$, plus $\frac{1}{64}$, &c.

As to the finding of an infinite series to express quantities sought, Mercator, the first inventor of the method, did it by division: but Sir Isaac Newton and M. Leibnitz have improved the doctrine very considerably: the first finding his series by the extraction of roots, and the second by another series presupposed.

To find a SERIES expressing a Quantity sought by Division. Divide the dividend by the divisor, as in common algebra, continuing the division till the quotient shew the order of progression, or the law, according to which the terms proceed to infinity. —

For example. Suppose $y + yx = v$, then $y = \frac{v}{1+x}$.

Then, by dividing v by $1+x$ according to the common rules for the division of algebra, we shall discover the law of the series; as is plain from the following operation;

$$\begin{array}{r} 1+x \overline{) v(v-vx+vx^2-vx^3+vx^4, \&c} \\ \underline{v+vx} \\ -vx \\ \underline{-vx-vx^2} \\ +vx^2 \\ \underline{+vx^2+vx^3} \\ -vx^3 \\ \underline{-vx^3-vx^4} \\ +vx^4, \&c. \end{array}$$

And, by the same method of investigation, of $y \sqrt{b \mp x}$ $x = a a$, we shall find $y = \frac{a a}{b \mp x} = \frac{a}{b} \mp \frac{a^2 x}{b^2} + \frac{a^2 x^2}{b^3} \pm \frac{a^2 x^3}{b^4} + \frac{a^2 x^4}{b^5}, \&c.$

To find the sum of the geometrical progression $1+x+x^2+x^3, +x^p$. Put $s=1+x+x^2+x^3, +x^p$; then $s x = x+x^2+x^3+x^4, +x^{p+1}$, and therefore, by subtraction, we have $s-sx=1-x^{p+1}$; consequently $s = \frac{1-x^{p+1}}{1-x}$. If x be a proper fraction and p infinite, then x^{p+1} being infinitely small, or less than any quantity assignable, the sum of $1+x+x^2+x^3, \&c.$ in infinitum, becomes $\frac{1}{1-x}$.

To find the sum (s) of $1+2x+3x^2+4x^3, \overline{p+1}x^p$. Here $s x$ is equal to $x+2x^2+3x^3+4x^4, \overline{p+1}x^p$ $+p+1 \times x^{p+1}$, and therefore $s-sx=1+x+x^2+x^3, -p+1 \times x^{p+1}$, and $s = \frac{1+x+x^2+x^3, \overline{p+1}x^p - p+1 \times x^{p+1}}{1-x}$.

H b

But

But $1+x+x^2+x^3, +x^p$ is equal to $\frac{1-x^{p+1}}{1-x}$, which

being substituted in the above value of s , gives $\frac{1-x^{p+1}}{1-x^2}$

$-\frac{p+1 \times x^{p+1}}{1-x}$, for the sum of the series $1+2x+3x^2$

$+4x^3, p+1 \times x^p$. If x be less than unity, and p in-

finite, the sum of the infinite series $1+2x+3x^2+4x^3,$

&c. will be expressed by $\frac{1}{1-x^2}$, because $\frac{p+1 \times x^{p+1}}{1-x}$

being (when p is infinite) infinitely small, may be re-

jected as inconsiderable. Let it be required to find the sum of the series $1+ax$

$+a+b \times x^2 + a+2b \times x^3 + a+3b \times x^4, a+p-1 \times b$

$\times x^p$. By an actual multiplication of the terms of

the series we shall have $1+ax+ax^2+ax^3+ax^4+ax^5,$

$+ax^p+bx^2+2bx^3+3bx^4+4bx^5, +p-1 \times b \times x^p$.

Now in order to find the sum of the terms of the first

part of the series, put $s=x^2+x^3+x^4, +x^p$, then $sx=$

$x^3+x^4+x^5, x^{p+1}$, and therefore $s-sx=x-x^{p+1}$: hence

$s=\frac{x-x^{p+1}}{1-x}$, and the sum of $1+ax+ax^2+ax^3+ax^4,$

$+ax^p$, becomes $1+a \times \frac{x-x^{p+1}}{1-x}$. Our next business is

to investigate the sum of the second part of the series,

viz. $bx^2+2bx^3+3bx^4+4bx^5, +p-1 \times b \times x^p$; in order

to which put $s=x^2+2x^3+3x^4, +p-1 \times x^p$, then $sx=$

$x^3+2x^4+3x^5, +p-1 \times x^p + p-1 \times x^{p+1}$. Hence we

get $s-sx=x^2+x^3+x^4+x^5, +x^p-p-1 \times x^{p+1}$. For

$x^2+x^3+x^4+x^5, +x^p$, substitute its value $\frac{x^2-x^{p+1}}{1-x}$,

and we shall have $s=\frac{x^2-x^{p+1}}{1-x}-\frac{p-1 \times x^{p+1}}{1-x}$, conse-

quently the sum of the proposed series $1+ax+a+b \times x^2$

$+a+2b \times x^3+a+3b \times x^4, +a+p-1 \times b \times x^p$, will be

expounded by $1+a \times \frac{x-x^{p+1}}{1-x} + b \times \frac{x^2-x^{p+1}}{1-x} - b \times$

$\frac{p-1 \times x^{p+1}}{1-x}$.

In the same manner may the sum of the series $\frac{m-1}{rm}$

$+\frac{m-2}{r^2m}+\frac{m-3}{r^3m}+\frac{m-4}{r^4m},$ &c. continued to m number of

terms, or of the series $\frac{m-1 \times n-1}{rmn} + \frac{m-2 \times n-2}{r^2mn}$

$+\frac{m-3 \times n-3}{r^3mn},$ &c. continued to m number of

terms, be easily found, and are respectively equal to

$\frac{1}{r-1} - \frac{r+r}{m \times r-1}$ and $\frac{1}{r-1} + \frac{2r-2r}{mn \times r-1^3} -$

$\frac{m+n-1 \times r+n-m-1 \times r}{mn \times r-1^2}$.

To Find a SERIES Expressing the Quantity sought, by Ex-

traction of roots.—Suppose $yy=1-xx$, then, by ex-

tracting the root on each side of the equation according

to the common rules, we shall find $y=1-\frac{1}{2}x^2-\frac{1}{8}x^4-$

$\frac{1}{16}x^6-\frac{1}{128}x^8-\frac{1}{256}x^{10},$ &c. See BINOMIAL Theo-

mere observation of feet and measure, such as we find in Plautus, Terence, and in Horace's satires, he thinks, is not sufficient to constitute verse; to determine the work to be poetical, or distinguish it from prose; unless it have some farther air or character of poetry, somewhat of the fable, or sublime. Hence it is that Horace calls his satires prose Sermones.

SERMONS, orations, or discourses delivered by the clergy of the Christian church, in their religious assemblies.

In the ancient church, immediately after the reading of the psalms, and lessons out of the scriptures, before the catechumens were dismissed, followed the sermon, which the bishop or some other, appointed by him, made to the people. This, being done in the presence of the catechumens, was therefore reckoned a part of the *missa catechumenorum*, or ante-communion service. Such discourses were commonly termed homilies, *ομιλῖαι*, which signifies indifferently any discourse of instruction to the people. Amongst the Latins they were frequently called *tractatus*, and the preachers *tractatores*.

Preaching, anciently, was one of the chief offices of a bishop; inasmuch that, in the African churches, a presbyter was never known to preach before a bishop in his cathedral church, till St. Austin's time. In the Eastern church, presbyters were indeed allowed to preach before the bishop; but this was not to discharge him of the duty, for still he preached a sermon at the same time after them. In the lesser churches of the city and country, the office of preaching was devolved upon the presbyters; but deacons never were allowed to perform it. There are numberless passages in the writings of the fathers, which speak of preaching as a duty indispensably incumbent on a bishop. Many canons of councils either suppose, or enjoin it: and, in the imperial laws, there are several edicts of the secular power to the same purpose.

It has been a question, whether laymen were ever allowed by authority to make sermons to the people. It is certain, they did it in a private way, as catechists, in their catechetical schools at Alexandria, and other places; but this was a different thing from public preaching in the church. Sometimes the monks, who were only laymen, took upon them to preach; but this was censured, and opposed, as an usurpation of an office that did not belong to them. Yet, in some cases, a special commission was given to a layman to preach: as in the case of Origen, who was licensed by Alexander, bishop of Jerusalem, to preach and expound the scriptures in the church, before he was in orders. As to women, whatever gifts they could pretend to, they were never allowed to preach publicly in the church; agreeably to the apostolic rule, "Let your women keep silence in the churches, &c." But they might teach those of their own sex, as private catechists, and prepare them for baptism. And this was the office of the deaconesses. The Montanists were a noted sect for giving the liberty of preaching to women, under the pretence of inspiration by the spirit; for they had prophetesses, women-bishops, and women-presbyters.

Next to the persons, the manner in which the office of preaching was executed, comes to be considered. And first it is observable, that they had sometimes two or three sermons preached in the same assembly, first by the presbyters, and then by the bishops. When two or more bishops happened to be present in the assembly, it was usual for several of them to preach, one after another, reserving the last place for the most honourable person. In some places, they had sermons every day, especially in Lent, and the festival days at Easter. In many places, they had sermons twice a day, for the better edification of the people. But this is chiefly to be understood of cities and large churches: for in the country parishes there was not such frequent preaching.

The next thing to be observed is, their different sorts of sermons, and different way of preaching. These are distinguished into four kinds: 1. Expositions of scripture. 2. Panegyric discourses upon the saints and martyrs. 3. Sermons upon particular times, occasions, and festivals. 4. Sermons upon particular doctrines, or moral subjects. There are examples of all these kinds in St. Chrysostom's and St. Austin's homilies, the two great standards of preaching, in the Greek and Latin churches. But,

But, though most of these were studied and elaborate discourses, penned and composed beforehand, yet some were also extempore, spoken without any previous composition, and taken down in short-hand from the mouth of the preacher. Origen was the first that began the way of extempore preaching in the church.

Upon this account it was usual for the preacher to usher in his discourse with a short prayer, for divine assistance. In this sense we are to understand St. Chrysostom, when he says, "We must first pray, and then preach." Sometimes, before they began to preach, they used the common salutation, *Pax vobis*, Peace be with you; to which the people answered, And with thy spirit. And sometimes they prefaced the sermon with a short form of benediction, especially in times of calamity and distress, or of happy deliverances out of them. Sometimes they preached without any text, and sometimes upon more texts than one. Neither did they entertain their auditory with light and ludicrous matters, or fabulous and romantic stories, such as those with which preaching so much abounded in the age before the Reformation.

And, as they were careful in the choice of their subject, so were they in the manner of dressing it up, and delivering it, that they might answer the true ends of preaching. St. Austin has laid down excellent rules, for the practice of Christian eloquence; and, if we will take his character of the ancient preachers, it was, in short, this: that their discourses were always upon weighty and heavenly matters, and their style answerable to the subject, being plain, elegant, majestic, and nervous; fitly adapted to instruct and delight, to convince and charm their hearers. It was no part of the ancient oratory to raise the affections of the auditory, either by gesticulations, or the use of external shews and representations of things in their sermons, that is now very common in the Romish church. As to the length of their sermons, scarce any of them would last an hour, and many not half the time. And among those of St. Austin there are many, which a man may pronounce distinctly, and deliver decently, in eight minutes. They always concluded their sermons with a doxology to the Holy Trinity. And it is farther observable, that the preacher usually delivered his sermon sitting, and the people heard it standing; though there was no certain rule about this, but the custom varied in different churches.

It was a peculiar custom in the African church, when the preacher chanced to cite some remarkable text, in the middle of his sermon, for the people to join with him in repeating the close of it. St. Austin takes notice of this in one of his sermons, where, having begun those words of St. Paul, "The end of the commandment is"—the people all cried out, "Charity, out of a pure heart." But it was a much more general custom for the people to testify their esteem for the preacher, and approbation of his sermon, by public applauses, and acclamations in the church. Thus, we are told, the people applauded St. Chrysostom's sermons, some by tossing their garments, others moving their plumes, others laying their hands upon their swords; and others waving their handkerchiefs, and crying out, "Thou art worthy of the priesthood, &c." Many of the auditors practised the art of notaries, and took down the sermons of the most eminent preachers, word for word, as they delivered them. By this means some of their extempore discourses were handed down to posterity, which else would have died with the speaking.

The Roman catholics call the sermon, the prone. After the gospel, the preacher goes to the bottom of the steps of the altar, on the epistle side, where he kneels down, and offers prayers to God for the action he is going about. Then he ascends the pulpit; where he first bows to the cross, and then to the chief of the congregation. He likewise crosses himself; and, whenever he pronounces the name of Jesus and Mary, he takes off his cap, and bows. In Italy, he does the same thing, whenever the reigning pope is named in the sermon. Before the bishop, or when the holy sacrament is solemnly exposed on the altar, it is usual to preach bare-headed.

The manner of preaching in Italy is very indecent, the behaviour of the preachers being like that of stage-dancers: they are extravagant in their gestures, they

strike with their hands and feet, roll their eyes, and walk from one end of the pulpit, which is very long and wide, to the other, with immoderate and ridiculous vivacity. Their finest sermons, says a celebrated traveller, are those that raise the most laughter. 'The Capuchins, adds he, never preach, but on terrible subjects; they seize their own beards, clap their hands, and scream enough to fright one. The other day, I heard a Carmelite, who was preaching to the repentant nuns of the holy cross, on the subject of Mary Magdalen. In order to raise a more exalted idea of the sacrifice his penitent had made of the pleasures of the world, he spent a whole quarter of an hour in painting her out as the most charming creature under heaven: not one feature, in the most perfect body, was omitted; and he talked more like a most accomplished painter, than a preacher.' In Italy, there are seldom any sermons, but in the time of Advent and Lent. The friars preach in their convents upon topics which we may call eternal; for they seldom lose sight of their founders, or of some particular practices, which they are fond of, such as the rosary, and scapulary, and St. Francis's girdle. In some cities of Italy, are itinerant preachers, who carry about with them little moveable pulpits.

In Spain they often preach in the public squares and high streets, and seldom fail of a numerous audience. The preachers take great pains to affect their hearers, and to this end they frequently strike their breast or face, and the whole congregation does the same thing. They who draw most tears are thought the best preachers.

The Greek Christians seldom have any sermons. Preaching, as Tournefort assures, is so far abolished, that there is scarce a pulpit to be seen in all their churches: however, when a father does attempt to mount the rostrum, he delivers himself in the most awkward manner imaginable; and has two crowns for his discourse, which consists only of a tedious train of empty words, without the least order or coherence, and which the preacher himself (says our author) understands no more than the people.

SERON of *Almonds*, is the quantity of 200 weight; of anise seeds, from 3 to 400; of Castile-sope, from 200 and a half to 300 and 3 quarters.

SEROSITY, in medicine, an aqueous liquor, or lymph, found in the blood, and other humours.

SERPENS, in astronomy, a constellation of the northern hemisphere, called more particularly, *Serpens Ophiuchi*. The stars in this constellation in Ptolemy's catalogue are 17, in Tycho's 19, and in Mr. Flamsteed's 59.

SERPENT, *Serpens*, in zoology, the name of a genus of animals, which Mr. Ray defines to be creatures breathing by means of lungs, having only one ventricle in the heart, having no feet, and having a long body, covered with scales. To which he adds, that in cold seasons they can bear hunger a long time. The greater part of the serpent class are poisonous, and dangerous in their bite, leaving a mischievous liquor in the wound, made by their tooth, which, mixing by this means immediately with the blood, is of fatal consequence; though the whole creature may be eaten with safety, or even the poisonous liquor, which does this mischief in the wounded, tasted without hurt.

Notwithstanding that serpents respire by means of lungs, they do not take in and discharge their breath by such short intervals as other animals, but what they have once inspired will serve them a long time; for as they are of a cold nature, and therefore their necessary warmth very small, they do not require such an eternally renewed supply of that pabulum of vital heat, as those which have more of it; and as with us they lie half the year torpid, and half dead, their vital warmth at that time, like fire smothered under ashes, barely exists, and needs perhaps no more air than what the creature took in at one inspiration, before its laying itself down for the season, which serves it till the life-renewing spring returns.

Serpents, according to Mr. Ray, may be divided into the poisonous and the harmless; the first having long dentes exerti, with poisonous liquors contained at their bottom, which, on biting, they discharge into the wound

wound: the others wanting these teeth, and this poison.

They may also be divided, in regard to their generation, into the oviparous and viviparous; but this is a less firmly founded distinction than may be supposed, since all serpents are truly and properly produced of eggs; and the only difference is, that some deposit their eggs in dunghills, and the like places, to be hatched by accidental heat, while others retain those eggs to be hatched in their own bodies, and so bring forth living young ones. Of the first kind is the common snake, of the latter the viper. *Ray's Syn. Quad. et Sup.*

SERPENT, *Bubalinus*. Mr. Cleyer has given a very remarkable account, in the German Ephemerides, of the prodigious size and voracious appetite of this serpent, and its manner of feeding. This gentleman assures us that they grow to the length of five feet, and are surprisingly daring in attacking large creatures for prey. Their neck, he observes, is so small, in proportion to the creature they seize; that it is a wonder that they can swallow them whole, which yet experience shews they certainly do, having no power of tearing them to pieces. This gentleman saw a complete stag taken out of the belly of one of these snakes, with all its limbs remaining on: and at another time a wild goat which had been swallowed in the same manner, and from another a complete porcupine, a very troublesome morsel; and there was once an instance, in the Molucca islands, of a woman big with child being thus sucked down whole by one of these creatures. *Ray's Syn. An.*

The method of their managing their prey is this: when thoroughly lank, lean and hungry, the snake lies in wait for any thing it can seize; he darts out upon the prey, and, seizing it with his mouth, winds his body round that of the creature; and this he is able to do with such force, that he will often, in twisting himself firmly round the creature, break the bones within its skin. This he continues, and at the same time is biting, with his terrible mouth, all the tender parts of the creature, till he has destroyed it; or, if it be an animal too strong to be killed by these simple folds, it will drag it to some neighbouring tree, and, tying it fast against that, draw its body so forcibly round it, as to crush all its bones to pieces by the help of that solid resisting body. The part it usually seizes with its teeth, at the same time, is the creature's nose, which he bites so forcibly as not only to stop the breath, but to occasion a discharge of blood, which helps to forward its destruction.

But the most singular attack, ever known to have been made by this creature, is that recorded by the same author, of its seizing a buffalo, which it destroyed in the manner above described, though it was a long time about it, and was obliged to have recourse to the method of tying it up to a tree, against which it broke its bones severally, with a noise that was heard to a great distance. When the creature had thus destroyed its prey, it continued breaking of the bones, till there was not one left whole in the body, and the whole resembled a shapeless mass of matter.

The jaws and throat of this, and of the other serpent kind, though small and narrow, are prodigiously extensible, and made so by nature, for the swallowing these morsels. The snake, when the prey lay in this state before it, licked it all over, and covered it thick with its saliva, and that so regularly, that the whole carcase looked as if daubed over with glue. This done, it opened its jaws to a monstrous extent, and sucked in the head of the prey, and continuing incessantly sucking, at length drew down the whole body.

This is a work of time, and very often two or three days are employed in it. And, when the animal is thus got down, the snake is swelled and bloated up all over with it, and is no longer in a state of offending, or even of defending itself, or so much as running away; and the people of the places where this species is common, well know this, and find it an easy thing to destroy them in this state, and are very happy when they catch one, as their flesh is a very delicate food. *Ephem. Germ. Ann. 12. Obs. 7.*

SERPENT, in music, a wind instrument, serving as a bass to the cornet, or a small shawm, to sustain a chorus

of singers in a large vessel. It had its name serpent from its figure, as consisting of several folds or wreaths, serving to take off its length, which would otherwise be six or seven feet: it is usually covered with leather, and consists of three parts: a mouth-piece, neck, and tail. It has six holes, by means of which they give it the compass of two octaves.

SERPENTARIA, VIRGINIAN SNAKEROOT: the root of a species of aristolochia growing in Virginia and Carolina. The root is small, light, bushy, composed of a number of strings or fibres issuing from one head and matted together, of a brownish colour on the outside, and paler or yellowish within.

SNAKEROOT has an aromatic smell, approaching to that of valerian, but more agreeable, and a warm bitterish pungent taste, which is not easily concealed or overpowered by a large admixture of other materials. It gives out its active matter both to water and rectified spirit, and tinges the former of a deep brown, the latter of an orange colour. Greatest part of its smell and flavour is carried off in evaporation or distillation by both menstrua: along with water there arises, if the quantity of the root submitted to the operation be large, a small portion of a pale coloured essential oil, of a considerable smell, but no very strong taste, greatest part of the camphorated pungency, as well as bitterishness of the root, remaining in the inspissated extract. The spirituous extract is stronger than the watery; not so much from its having lost less in the evaporation, as from its containing the active parts of the root concentrated into a smaller volume; its quantity amounting only to about one half of that of the other.

This root is a warm diaphoretic and diuretic. It is reckoned one of the principal medicines of the alexipharmac kind; and as such is in general use, in low malignant fevers and epidemic diseases, for supporting the vis vitæ, raising the pulse, promoting a diaphoresis, and correcting a putrid disposition of the humours. It is given, in substance, from a few grains to a scruple or half a dram; in decoction or infusion, to a dram and upwards. Tinctures of it are prepared in the shops, by macerating two or three ounces of the root in a quart of proof spirit, or of a spirituous alexeterial water mixed with one sixth its quantity of distilled vinegar, which last ingredient is an excellent addition to these kinds of medicines in acute diseases.

SERPENTARIUS, in astronomy, a constellation of the northern hemisphere, called also Ophiuchus. The stars in this constellation, in Ptolemy's catalogue, are 29, in Tycho's 25, and in Mr. Flamsteed's 69.

SERPENTINE, in general denotes any thing that resembles a serpent; hence the worm or pipe of a still, twisted in a spiral manner, is termed a serpentine worm.

SERPENTINE MARBLE, a kind of marble spotted like the skin of a serpent, whence its name. The ancients called it ophites, from *opsis*, a serpent.

SERPENTINE VERSES, such as begin and end with the same words.

SERPIGO, in medicine, a species of herpes, vulgarly called a ring-worm. See HERPES.

SERPILLUM, *Mother of Thyme*, in botany, a species of thyme. See THYME.

SERRATED, in general, something indented, or notched, in the manner of a saw.

SERRATUS, in anatomy, a name given to several muscles of the body from their resembling a ferra or saw. — As

SERRATUS *anticus minor*, which arises thin and fleshy, from the second, third, fourth, and fifth superior ribs; and ascending obliquely, it is inserted fleshy into the processus coracoides of the scapula, which it draws forward. It also helps in respiration.

SERRATUS *anticus major*; which comes from the whole basis of the scapula, and is inserted into the seven true ribs, and first of the false ribs, by so many distinct portions representing the teeth of a saw.

SERRATUS *posticus superior*, ariseth by a broad and thin tendon from the two inferior spines of the vertebrae of the neck, and the three superior of the back; and, growing fleshy, is inserted into the second, third, and fourth ribs by so many distinct indentations. These two

help

help to draw the ribs upwards, and bring them to right angles with the vertebræ; and, consequently, make the cavity of the thorax wider and shorter.

SERRATUS posticus inferior, arises with a broad and thin tendon from the three inferior spines of the vertebræ of the back, and from the two superior of the loins; its fibres, ascending obliquely, grow fleshy, and are inserted by four indentations into the four last ribs.

SERVANT, a term of relation signifying a person who owes and pays a limited obedience for a certain time, to another in quality of master.

SERVETISTS, a name given to the modern anti-trinitarians, from their being supposed to be the followers of Michael Servetus, who in the year 1559, was burnt at Geneva, together with his books.

SERVICE, in law, is a duty which a tenant, by reason of his fee, owes to his lord.

SERVING, in the sea-language, the act of winding a quantity of leather canvas, or cordage round any rope, to preserve it from being galled or rubbed by the friction produced at sea by the agitation of the ship on the waves. The materials applied to this purpose are termed service. See **PLAT**, **ROUNDING** and **FRESHEN**.

SERVITES, a religious order in the church of Rome, so called from their peculiar attachment to the Blessed Virgin.

This order was founded by seven Florentine merchants, viz. Bonfili Monaldi, John Manetti, Benet de Lantella, Bartholomey Amidei, Ricouere Lippe Ugucion, Gerardin Sostegni, and Alexis Falconieri. These gentlemen, with the approbation of the bishop of Florence, renounced the world, and lived together, in a religious community, on Mount Senar, two leagues from that city. When they first appeared in the black habit given them by the bishop, the very children at the breast cried out, "See the servants of the Virgin;" and this miracle determined them to take no other name than that of Servites, or servants of the Virgin.

Some time after, finding the distance of their solitude from Florence too inconvenient, on account of the necessity they were under of subsisting by alms, they procured a little hospital or monastery to be built without one of the gates of the city: and this was the humble origin of the famous monastery of the Annunciado at Florence.

In length of time this order increased to such a degree, that it became divided into twenty-seven provinces, and enjoyed several privileges by grants from the popes. Formerly they eat no flesh meat, and observed several other austerities, which afterwards they dispensed with. They boast of having produced several cardinals and other eminent persons, especially men of learning, among whom was the famous father Paul, who wrote the history of the council of Trent.

There are likewise nuns of this order, who have several monasteries in Germany, Italy, and Flanders.

SERVITOR, in the university of Oxford, a scholar, or student, who waits upon another for his maintenance there.

SERVITORS of Bills, servants or messengers of the marshal of the King's-bench, sent with bills or writs, to summon people to that court: these are now called tip-staves.

SERUM, the thin watery part of the blood. See **BLOOD**.

The word is Latin, and literally signifies whey.

SERUM Aluminosum, *alum-whey*, a form of medicine prescribed in the late London Pharmacopœia, made of a pint of milk boiled to whey with a quarter of an ounce of alum.

SESSAMOIDEA OSSA, in anatomy, several small bones placed between the joints of the fingers and toes.

The word is formed from the Greek, *σισαμιν*, an Indian seed, and *ειδος*, resemblance.

SESAMUM, the oily grain plant, in botany, a genus of plants, the flowers of which are produced from the wings of the leaves, without any foot-stalk; the flower-cup consists of one leaf, divided into five long slender segments: the flower is of one leaf, in shape like those of the fox-glove: the pointal, which rises in the middle of the flower, afterwards becomes an oblong four-corner-

ed pod, divided into four distinct cells, which are replete with esculent seeds.

In England, these plants are preserved in botanic gardens as curiosities. Their seeds must be sown in the spring upon an hot-bed; and, when the plants are come up, they must be transplanted in a fresh hot-bed, to bring them forward. After they have acquired a tolerable degree of strength, they should be planted into pots, filled with rich light sandy soil, and plunged into another hot-bed; for, if these plants are not brought forward thus in the former part of the summer, they will not produce good seeds in this country; though, after they have flowered, if the season is favourable, they may be exposed in a warm situation, with other annual plants. When these plants have perfected their seeds, they decay, and never continue longer than one season.

SESELI-Seed, in the materia medica, the name of a seed of a plant, called also by some libanotis, and growing three or four feet high, with leaves like fennel, but of a paler green. It is a native of warm climates. The seed should be chosen moderately large, of a longish shape, heavy, clean, and of a greenish colour, fresh, and of a grateful smell. It affords, by distillation, a very large quantity of an essential oil, and is hot and dry. It incises, opens, and discusses, and is cephalic, neurotic, pectoral, nephritic. It is good against epilepsies, apoplexies, vertiges, and all disorders of the head and nerves.

SESQUI, a Latin particle signifying a whole and a half; which, joined with *altera*, *terza*, *quarta*, &c. is used by the Italians in their music, to express a kind of ratio's, particularly species of triple time.

SESQUI-ALTERAL PROPORTION, in geometry and arithmetic, is when any number or quantity contains another once and an half, and the number so contained in the greater, is said to be to it in subsequi-alteral proportion.

SESQUI-DUPLICATE Ratio, in geometry and arithmetic, is when any number or quantity contains another twice and a half.

SESSILE Roots, in gardening, imply such tuberosc roots as adhere to the stalk.

SESSILE Leaf, a leaf fixed immediately to the stalk, or root, without any foot-stalk.

SESSION, the sitting of an assembly or council.

SESTERCE, a silver coin in use among the ancient Romans; being the fourth part of the denarius, and originally contained two as's and a half; or something more than seven farthings sterling.

SET, or **SETTS**, a term used by farmers and gardeners to signify the young plants of the white-thorn, and other shrubs, with which they raise their quick-set hedges, &c.

The white-thorn is the best, of all trees, for this purpose, and under proper regulations, its sets seldom fail of answering the farmer's utmost expectations.

The first thing to be considered by the person who is about to plant a quick-set hedge, is what nature the land is of where it is to stand, as whether it is clay, sand, or gravel. It is always proper to take the sets from a worse land than that they are to be planted on, otherwise they will never grow well. The sets are about the thickness of a man's thumb, and cut within four or five inches of the ground. If the quick is intended only for a hedge, without a bank or ditch, let the sets be planted almost perpendicular in two rows, at about twelve inches distance from each other; and if there is to be a ditch and a bank, that is to be first provided. The ground is to be marked out with a line, and a ditch dug three feet wide at the top, one foot wide at the bottom, and two feet deep. When the ditch is digging, on that side where the quick is to stand, let the turf be laid evenly on the ground with the grassy side downwards: upon this some fine mould is to be laid to bed the quick-sets in, and they are to be laid upon it with their ends inclining upwards, and at about twelve inches asunder. They must be carefully gathered, and such as are straight, smooth, and well-rooted, are only to be chosen. At every thirty feet there should be planted with the sets a young oak, ash, or some other such tree, to grow up along with the hedge. When a complete row of the sets is thus laid, cover them with a layer of fine mould, and lay over that

another layer of the turf; and upon this a third layer of mould, so deep, that its surface may be a foot above the row of sets: on this bed place another row of the like sets at the same distances, but placed between the others; cover this as the other, and then make up the bank with the earth dug out of the bottom of the ditch, and on its top set the dry, or dead hedge; this will shade the under plantation, and will be a defence till the sets are grown up into a live hedge. The stakes for the dead hedge are to be driven into the bank so low as to reach the firm ground, and are to be placed at two feet and a half distance from one another.

Oak-stakes are the best for this purpose, and fallow and black thorn are esteemed next to these. The small bushes cut from them must be laid below, but not too thick, that they may shade the young plantation without smothering it, and defend its young shoots from the biting of cattle: the long bushes are to be laid at top to bind in the stakes by interweaving them. To add a farther strength to the hedge, it may be eddered, as the farmers call it: this is binding the tops of the stakes with some small long poles, or sticks on each side. When this is all done, the stakes should be new drove a little, because the making the hedge, and the eddering it, are apt to loosen them a little.

The young plants must be constantly weeded, and great care must be taken to preserve them from the bitings of cattle, especially of sheep. If they have been cropped, or are not found to grow well, it is a good custom among the farmers to cut them down to the ground, or within an inch of it, for after this they usually send out new roots, and shoot very vigorously. *Mortimer's Husbandry.*

SETACEUS *Vermis*, in natural history, a name given by Dr. Lister to that long and slender water-worm, which so much resembles a horse-hair, that it has been supposed by the vulgar to be an animated hair of that creature.

SETHIANS, in ecclesiastical history, christian heretics, who appeared in Egypt during the second century. They paid divine honours to Seth, whom they considered as the Messiah, but pretended that he was made by a third divinity, and substituted in the room of the two families of Abel and Cain, which had been destroyed by the deluge. These heretics continued in Egypt above two centuries, and, as they did not consider debauchery as a crime, had many followers.

SETON, in surgery, a wound made generally in the hind part of the neck, and kept in a state of suppuration by means of a small skain of silk, cotton, or horse-hair, passed through the skin by means of a needle or probe. It is of use to divert a defluxion of humours from the eyes.

SETTER, among farmers, implies a wound made in the dew-lap of an ox or cow, and a tent made of the root hellebore after inserted into it, whereby the wound is kept in a constant state of digestion, and the humours find a vent.

SETTEE, a small ship used principally by the Italians and Greeks in the Mediterranean. It is equipped with two masts, which are furnished with lateen sails. See the article **LATEEN**.

SETTING, in navigation, the act of marking the bearings of any distant object by the compass.

SETTING, in astronomy, implies the sinking of a heavenly body below the horizon.

SETTING, among sportsmen, implies a method of taking partridges by means of a dog properly trained for that purpose.

The setting-dog generally used is a long land-spaniel, taught by nature to hunt partridges more than any other game, and in his untaught state running over the fields in search of them; but being taught, the creature is under such excellent command, that he will, in the midst of his highest career, attend the least hem from his master, and stand still to look in his face and to take his orders by the slightest signals; and when he is so near his game that it is almost in his mouth, he will stand stock-still, or lye down on his belly, till his master arrives, and he receives his directions. The setting-dog being taken to the haunt of the partridges, is to be

cast off, and sent to range; but he must be made to keep near the sportsman, and not to run wildly on, but to beat all the ground regularly. If in the dog's ranging he stops on a sudden, the sportsman is to make up to him, and as there is certainly game before him, he must be ordered to advance; if he refuses this, and looks back and shakes his tail, it is a signal that they are close before him, and the sportsman is then to take a circumference, and look carefully before the dog's nose, to see where they are, and how they lie; then going up and staking down one end of the net, he is to command the dog to lie still, and to draw the net gently over the birds, then making in with a noise, he is to spring them, and they will be entangled and taken, as they rise.

SETTLING, in navigation, the act of lowering any object by the increase of the distance from it.

SEVENTH, in music, an interval, of which there are four kinds.

The first is called the diminished or defective seventh, and consists of three tones and three greater semi-tones.

The second is composed diatonically of seven degrees and six intervals, of which four are tones, and the rest greater semi-tones; and, chromatically, of ten semi-tones, six whereof are greater and four lesser.

The third is composed diatonically like the former, of seven degrees and six intervals, six whereof are full tones, and the seventh a greater semi-tone; so that only one semi-tone is wanting to complete the octave; and, chromatically, of eleven semi-tones, six whereof are greater, and five lesser.

The fourth, called the redundant seventh, is composed of five tones, a greater semi-tone and a lesser; so that it wants only the difference between the greater and lesser semi-tone, to render it equal to the octave.

In thorough bases, the seventh is marked by a figure of 7, but if it be accidentally flat, by *b* 7, or 7 *b*; if sharp, *#* 7, or 7 *#*.

SEVERANCE, in law, the separating of two parties joined in one writ.

SEWER, a drain, conduit, or conveyance, for carrying off water, suillage, &c. from a house, street, field, or the like.

SEWER, in the household, implies an officer who comes in before the meat of a king or nobleman, to place it properly on the table.

SEWED, in the sea-language, the state of a ship when the water has ebbed from her as she lies on the ground.

SEX, something in the body which distinguishes the male from the female.

SEXES of flowers, those parts of flowers which perform the same offices in the vegetable world, that the similar parts of animal bodies perform in that department of nature.

"It is in the flowers of vegetables only, says the learned Dr. Watson, that the parts subservient to generation are produced. Simple flowers (I use the term in opposition to the compound flowers of the botanists) are either male, female, or hermaphrodite. By male flowers I would be understood to mean those which are possessed only of those organs of generation, analogous to the male parts of animals; and these are what former botanists have denominated stamina and apices, but are named more properly by Linnæus since, filamentum and anthera. The female flower is only endowed with parts like those which perform the office of generation in females; and these are the pistillum and its appurtenances, which, by Linnæus, with his accustomed accuracy, are divided into three parts, viz. the germen, stylus, and stigma. The hermaphrodite flower, which constitutes the great bulk of the vegetable creation, is possessed of all these parts in itself, and is itself thereby capable of propagating its species without any foreign assistance; which, by many incontestable experiments, it has been found, neither the male nor female flower simply, is able to do.

"Much the greater part of plants, as I have just hinted, have hermaphrodite flowers; but there are some, which have both the male and female flowers growing from the same root. Such are maize, or Indian corn, nettles, box, elm, birch, oak, walnut, beech, hazel, hornbeam, the plane-tree, pine, fir, cypress, cedar, the larch-

larch-tree, melons, cucumbers, gourds, and several others. In many of these, though the male and female flowers are at considerable distances, the farina fecundans, which Providence, on account of its being liable to be spoiled by rain, or dissipated by winds, has provided in great abundance, is conveyed to the female by means of the atmosphere. In this class of vegetables, the produce of the farina fecundans is much greater than in others, because the produce is much more precarious, than in those plants which have hermaphrodite flowers; as the impregnation of the latter may be performed within their own calyx; whereas the former must necessarily commit their farina to the circumambient air. It is for this reason, that if during the time of the flowering of those plants, the weather be either wet or stormy, their produce of fruit will be very inconsiderable, from the spoiling or dissipation of the male farina. Thus, independent of frosts, the fruit of the nut and filberd-tree, will be most numerous in those years, in which the months of January and February are least stormy and wet; as at that time their flowers are produced. For the same reason a stormy or wet May destroys the chesnuts; and the same weather in July prodigiously lessens the crops of maize or Indian corn, as its spikes of male flowers stand lofty, and at a considerable distance from the female. In the same manner a judgment may be formed of the rest of these plants.

"Some of the more skilful modern gardeners put in practice, with regard to melons and cucumbers, the very method mentioned by Theophrastus two thousand years ago, in regard to the palm-tree. As these plants, early in the season, are, in this climate, confined to frames and glasses, the air in which they grow, is more stagnant than the open air, whereby the distribution of the farina fecundans, so necessary towards the production of the fruit for the propagation of the species, is much hindered; to obviate which, they collect male flowers, when fully blown, and presenting them to the female ones, by a stroke of the finger they scatter the farina fecundans therein, and this prevents the fruit from falling off immaturally.

"Besides the vegetables abovementioned, which bear both male and female flowers on the same root, there are others which produce those necessary organs upon different roots. In the number of those are the palm-tree, hops, the willow-tree, mistletoe, spinach, hemp, poplar, French and dog's mercury, the yew-tree, juniper, and several others. Among these the valisneria of Linnæus, as to the manner in which its male flower impregnates the female, is one of the most singular prodigies in nature. The manner of this operation is figured by Micheli, in his *Nova Plantarum Genera*, and described by Linnæus, in the *Hortus Cliffortianus*. As that elaborate and expensive work is in very few hands, in such only as owe it to the munificence of Mr. Clifford of Amsterdam, of which number I with pleasure acknowledge myself one, I will here lay before you a short account thereof:

"The valisneria grows in rivulets, ditches, and ponds, in many parts of Europe. The male plant, which is continually covered with water, has a short stalk, upon the top of which its flowers are produced. As this top never reaches the surface of the water, the flowers are thrown off from it, and come unopened to the surface of the water; where, as soon as they arrive, by the action of the air, they expand themselves, and swim round the female flowers, which are blown at the same time.

"These last have a long spiral foot-stalk, by which they attain the surface of the water, and, remaining there in flower a few days, are impregnated by the male flowers detached from the stalk at the bottom. This operation seems to be thus directed, as the farina fecundans could not exert its effects in so dense a medium as water; and we find, that even the hermaphrodite flowers of water-plants, such as those of potamogeton, ranunculus aquaticus, hottonia, and nymphæa, these, I say, never expand themselves, until they reach the surface of the water.

"But to return: it was not possible for me, without premising these things, to make evident what I intended, in relation to the safely denominating the sexes of plants;

as it is to this last class that the wrong application has been made by botanical writers. This error seems to have been first introduced so early as by Dioscorides, and has been continued through a great variety of writers even to our own time. It is most certain, that those plants which produce the seed, ought to be considered as females; but it happens that, in the French and dog's mercury, the seeds are produced in the female plants by pairs; and these are contained in a capsule, which was thought to resemble the scrotum of animals; and from this testiculated appearance they called these plants males, and the others females.

"Dioscorides, when treating of mercurialis, or what we here call French mercury, says, that 'the seed of the female is produced in bunches, and is copious; that of the male grows near the leaves; that it is small and round, and is disposed in pairs like testicles.' Dodonæus, Lobel, Delechamp, John and Caspar Bauhin, Morrifon, Tournefort, and Boerhaave, in their several works, have in this followed Dioscorides, and have denominated the seed-bearing plant of this kind, the male; and the other, the female. Fuchsius and John Bauhin likewise call the cynocrambe or dog's mercury, which bears fruit, the male; and the spiked one with male flowers only, the female. This mistake is observable in hemp, hops, and spinach.

"We observe, that the operations of nature are carried on most usually by certain general laws, from which however she sometimes deviates. Thus almost all plants have either hermaphrodite flowers, or male and female flowers, growing from the same root, or male and female flowers from different roots: but there are a few of another class, which from the same root furnish either male and hermaphrodite flowers, or female and hermaphrodite flowers. Of this kind are the mulberry-tree, the mura or plantain-tree, white hellebore, pellitory, arrach, the ash tree, and a few others. But of this class the empetrum or berry-bearing heath is the most extraordinary; as of this are found some plants with male flowers only, others with both male and female flowers separately, and still others with hermaphrodite flowers." *Philos. Trans. Vol. XLVII.*

The late ingenious Dr. Allston, king's botanist in Scotland, has endeavoured to overturn the whole doctrine of the sexes of plants, by shewing that the farina fecundans is not necessary to the production of fertile seeds. We shall add the following instances which he has brought to support his doctrine.

"In the spring 1737, I transplanted, says he, three sets of common spinage, long before it could be known, whether they were flowering or seed-bearing plants, from a little bed on which they were raised, into a place of the garden, full eighty yards distant, and almost directly south; there being two haw-thorn, and three holly hedges, all pretty thick and tall, between them and their seed bed; and no other spinage in the garden, nor so near them by far: all the three proved fertile plants, and ripened plenty of seeds. I sowed them, they grew, and prospered as well as any spinage seed possibly could do. This, I own, made me, at first, call in question the sexes of plants, which I formerly too implicitly believed.

"The same year, a few plants of the common hemp, which I had raised for a specimen from the seed, being accidentally destroyed when very young; and finding afterwards, about the end of June, a pretty strong but late plant of hemp, growing in the inclosure to the east of Holyrood house, commonly called the bowling green, by itself; I caused great care to be taken of it; there not being that year any hemp raised within a mile of it, that I could find. This plant grew luxuriantly; and, though bad weather in the autumn made me pluck it up a little too soon, yet I got about thirty good seeds from it, which the succeeding spring produced as thriving male and female plants as if the mother hemp had stood surrounded with males. And in the spring 1741, I carried two young seedling plants of the French mercury, long before there was any in flower, from the city physic garden, the only place where it was then to be found in this country, to the king's garden at the abbey, which are more than 700 yards distant from one another, with many high houses, trees,

trees, hedges, and part of a hill between them: and planted one of them in one inclosure, where it was shaded from the sun the greatest part of the day; and the other, in another, twenty-five yards distant, exposed to the south and west. Both plants ripened fertile seeds; and the last shed them so plentifully, that it proved a troublesome weed for several years: though none of the species was to be found in that garden, for more than twenty years preceding.

"Hence, the dust of the apices of these species of plants cannot, on any account, be called their genitura. And the same may be said of the lupulus, according to Mr. Tournefort's observation; of the bryonia, as noticed by Mr. Miller; also of Mr. Geoffroy's maize.

"One year, observing two strong tulips growing together, in an inclosure surrounded with a tall and thick quick-set haw-thorn hedge; I cut down two or three more tulips, which stood at some distance from them so as to leave none within that inclosure, save the two I mentioned: out of these, gently opening the petals, I plucked all the stamina with their apices still intire. The consequences of this too rude castration, were a considerable extravasation of the juices, in the bottom of the flower, and a sudden decay of the ovarium or fruit, which never increased, but turned yellow, shrunk, and withered. In order to discover whether this abortion was owing to the wounds, or to the want of the dust of the apices; I suffered these two tulips to remain in the place where they were: and next season, with the same precaution that no other tulips should flower within the inclosure, I opened the petals, and took out carefully, not the stamina, only, but all the apices; which prevented any sensible bleeding of the parts. This more gentle castration they bore perfectly well: the ovarium suffered nothing, in either of them, but increased, and came to maturity, quite full of seeds." See the *Essays Physical and Literary, read before a Society in Edinburgh*, Vol. I. Page 205.

SEXAGENARY, something relating to the number sixty.

SEXAGENARY, or *Sexagesimal, Arithmetic*, implies a method of computation proceeding by sixties; such as is used in the division of a degree into sixty minutes, of a minute into sixty seconds, of a second into sixty thirds, &c.

SEXAGESIMA, the second Sunday before Lent, so called because near sixty days before Easter.

SEXAGESIMALS, or *SEXAGESIMAL Fractions*, are fractions whose denominators are in a sexagecuple ratio; that is, a prime = $\frac{1}{60}$, a second = $\frac{1}{3600}$, a third = $\frac{1}{21600}$, &c.

SEXANGLE, in geometry, a figure containing six angles, and consequently six sides.

SEXTANS, a word used by the old Romans to signify the sixth part of any weight, measure, &c.

SEXTANT, in geometry, signifies the sixth part of a circle, or an arch containing 60 degrees.

SEXTANT is also the name of a mathematical instrument, whose limb contains sixty degrees.

SEXTILE, an aspect of the planets, when they are two signs or sixty degrees distant from each other.

SEXTON, an officer in the reformed churches, whose office it is to take care of the vessels, vestments, &c. belonging to the church, and to attend the minister, church-wardens, &c. at their meetings.

SEXTUPLE, in music, implies a mixed sort of triple time, which is beaten in double time.

SEXUALISTÆ, a term used by botanical authors, to signify those writers who have established the classes of plants upon the difference of the sexes, and parts of fructification of plants; such as Linnæus, and many others. See the article *SEXES of Flowers*.

SHAD, the name of a sea-fish, of the herring kind, called also the mother of the herring, and by some authors clupea.

It is very common in many seas, and in some of our large rivers where the tide ebbs and flows. They run up these streams in great numbers during the months of March and April, when they are very fat; in May they become lean, and then return again to the sea.

SHADOW, in optics, a privation, or rather a diminution of light, by the interposition of some opaque body.

A shadow is of itself invisible; and, therefore, when we say we see a shadow, we partly mean that we see bodies placed in the shadow, and illuminated by light reflected from collateral bodies; and, partly, that we see the confines of the light. See the article *LIGHT*.

If the opaque body that projects the shadow be perpendicular to the horizon, and the place it is projected on be horizontal, the shadow is called a right shadow; and such are the shadows of men, trees, buildings, mountains, &c. But if the opaque body be placed parallel to the horizon, the shadow is called a versed shadow; as the arms of a man stretched out, &c.

The Laws of the Projection of SHADOWS from opaque Bodies. 1. Every opaque body projects a shadow in the same direction with its rays; that is, towards the part opposite to the light. Hence, as either the luminary or the body changes place, the shadow likewise changes. 2. Every opaque body projects as many shadows as there are luminaries to enlighten it. 3. As the light of the luminary is more intense, the shadow is the deeper: hence the intensity of the shadow is measured by the degrees of light that space is deprived of. 4. If a luminous sphere be equal to an opaque one it illuminates, the shadow, which this latter projects, will be a cylinder, and consequently will be propagated still equal to itself, to whatever distance the luminary is capable of acting; so that if it be cut in any place, the plane of the section will be a circle, equal to a great circle of the opaque sphere. 5. If the luminous sphere be greater than the opaque one, the shadow will be conical. If, therefore, the shadow be cut by a plane, parallel to the base, the plane of the section will be a circle; and that so much the less as it is a greater distance from the base. 6. If the luminous sphere be less than an opaque one, the shadow will be a truncated cone; and, consequently, grows still wider and wider; and therefore, if cut by a plane, parallel to the section, that plane will be a circle, so much the greater as it is further from the base.

Of SHADOWS from the Sun. The sun being vastly larger than the whole globe of the earth, must give all its shadows pointed, by reason it illumines more than half of them.

In consequence of this demonstration, we might conclude, that all the sun's shadows must be less than the bodies that project them, and diminish more and more as they recede further and further. Now this would be true were there any relation between the body illuminated and the body illumining; but as all objects on the earth are so small in comparison of that star, the diminution of their shadows is imperceptible to the eye, which sees them always equal; i. e. either broader or narrower than the body that forms them: on this account all the shadows caused by the sun are made in parallels.

From the whole it appears, that to find the shadow of any body whatever opposed to the sun, a line must be drawn from the top of the luminary perpendicular to the place where the foot of the luminary is to be taken: and through this place an occult line is to be drawn through one of the angles of the plan of the object, and another from the sun to the same angle; and the intersection of the two lines will shew how far the shadow is to go: all the other lines must be drawn parallel thereto.

The shadows of the sun are equal in objects of the same height, though at a distance from each other. See plate CXIV. fig. 2.

Experience teaches, that stiles, or elevations of the same height, removed to a distance from each other, do yet project equal shadows at the same time: for they are lengthening and shortening, in proportion as the sun comes nearer, or recedes further off; one or other of which he is continually doing.

For this reason, when the shadow of an object is to be cast any way, you must determine the place of the sun, and the point underneath, to draw two occult lines from the same, for the extremity of the shadow; as here the palisade A gives the extreme of its shadow in B: and if

Shadows

Fig. 6.

Fig. 1.

Segment.

Fig. 3.

from this point B, you draw a point of sight C, this line B C will be the shadow of the palisade D, as well as that of A, and of all the rest in the same line to the very point of sight.

In effect, it must be held for a certain maxim, that shadows always retain the same point of sight as the objects. On the footing of this observation, that objects of the same height give equal shadows; if you would give the shadow of the palisades, E, F, which are of the same height as A, D, take in your compasses the distance A D, and set it on the foot of the palisade E, by which you will have E G; then from G draw a line to the point of sight C; and thus you are to proceed, let the number of walks be ever so great.

Though the sun is made to appear in this figure, it must not be supposed that he is so near the objects; the design being only to shew, that the rays proceed from him in this manner, when at such a height, though far without the limits of the piece; as *fig. 3.* which yet has the line for the foot of the object A B; and those of the rays of the sun C, C, C, because these are always required for finding the extremities of the shadows.

The shadow of the object O is found by continuing the line A B, and making it rise over the steps, and against the wall, till cut by the ray in the point S, by the rays passing over the corner of the object, and from S drawing a line to the point of sight T.

To find the shadow of the object P, it must be remembered that the foot of the light must always be supposed on the plane where the object is placed. Accordingly, the ray C, cutting the little line A B, shews how far the shadow of the little object P must go, to be thence drawn to the point of sight T. The object V casts its shadow all along, though in its way it descends into a ditch.

The shadow of the wall R is found by the same rule as the rest; as appears from the lines A B and the ray C.

SHADOWS by Torch-Light. The shadow of an erect pyramid by torch-light falls as it would by the light of the sun; and in both cases there is but one line, whereon the vertical point of the pyramid will be found.

Upon the planes B C D E (*plate CXIV. fig. 4.*) draw the diagonals E B and D C; through the central point F, raise the perpendicular F A; and from the four points, B, C, D, E, draw lines to the point A, and the pyramid will be erected.

Then, to find its shadow, draw an indefinite line from its basis G of the illuminating body, passing through F; and from the central flame of the torch H draw another line over the vertex of the pyramid in the line G F, till it cut the point I, which point will limit the shadow of the pyramid.

Lastly, draw a line from C to I, and another from E to I, and the triangle C I E will be the shadow of the pyramid. To gain the shadow of an inverted pyramid draw perpendicular lines from the angular points of its base, and form the subjacent plane, by means thereof, after the manner directed for the sun.

And from all the angles of this plane draw lines to the base of the torch G; then from H, the central point of the flame, draw other lines touching all the angles of the base of the inverted pyramid, and dividing those of the plane, whereby the shadow will be defined.

Shadows from the sun are cast all the same way, and have the same disposition; it being impossible that the sun should occasion one shadow towards the east, and another towards the west, at the same time.

It is true, in different times of the day, it makes this difference; but never in one and the same hour.

But the torch, candle, and lamp, have always this effect; for in what place soever one of these luminaries be found, provided there be a number of objects about them, the shadows will be cast various ways; some to the east, some to the west, some to the north, and others to the south, according to the situation of the objects around the luminary: the foot of which, here represented by A, (*fig. 5.*) serves as a common center, from which they all proceed: and the flame, here represented by B, shews where they are to terminate, though at different

distances; as the nearest produce the shortest shadows, and the remotest the longest.

SHADOWS on several Parallel Planes. The first plane here is the floor, whereon the chair A (*fig. 6.*) stands; the second plane is the upper part of the table, parallel to the first, and may be either above or below it. There might also be more of these planes, wherein to find the foot of the illuminating body, in order to come at the shadow of the object. Suppose the foot of the illuminating body to be C, and the upper flame B; from the points C and B draw lines through the upper and under parts of the object D, which will give the shadow E upon the table.

To find the shadow of the chair A, which is placed on the ground, determine the foot of the luminary on the table in C on the ground: this is easy by the following instructions. From the point of distance, which is here supposed to be without the limits of the paper, draw a line through the foot of the table F; then from the angle G upon the table let fall a perpendicular, cutting the line F in the point H, and from H draw a parallel to the base H I, which is equal to the upper part of the table, and will direct to the thing required. For drawing a line from the point of sight K, through the foot of the luminary C, to the extremity of the table L; from the same point L, let fall a perpendicular to H I, which will give the point M.

Then from M draw a line to the point of sight K, in which line M K the foot of the luminary will be found.

To determine the precise point, let fall a perpendicular from the point C, which, cutting the line M H, will give the point N for the foot of the luminary.

This point N being thus found, there will be no difficulty in finding the shadow of the chair A, the method being the same as for the other objects taught before; that is, from the foot of the luminary N draw lines through all the angles of the plane of the chair, and other lines thro' the upper part of the chair from the luminary B; these latter, by intersecting the former, express the bounds of the shadow. For the rest, the figure gives sufficient directions.

When two luminaries shine on the same object, two shadows must be produced; each of the luminaries occasioning its respective shadow, and that in proportion to the circumstances of the luminary.

If such luminaries, when at equal distances, be equal, the shadows themselves must be equal: but if there be any disproportion, that is, if one of them be a little bigger than the other, or one of them a little nearer the object than the other, the shadows will be unequal.

Thus the object O, (*plate CXIV. fig. 7.*) being illuminated by two candles, the one near at hand in P, the other farther off in Q, it is evident the shadow of the candle P will be deeper than that of the candle Q, as is expressed in the figure.

The rules for such shadows are the same with those already given, both for the sun and the torch.

From what has been observed before may be drawn this conclusion, that the same object may project shadows of divers forms, though still illumined on the same side; the sun giving one form, the torch another, and the daylight no precise form at all.

The sun always makes its shadow equal to the object, that is, projects it parallelwise.

It is certainly of consequence to all painters, engravers, &c. to observe these rules precisely, and not to take the rules for candles, lamps, and the like, in lieu thereof, as is too frequently done.

The shadow of a torch, or flambeau, is not projected in parallel lines, but in rays proceeding from a center, whence the shadow is never equal to the body, but always bigger, and grows more so as it recedes farther off. It appears therefore a gross abuse to represent the shadow of a torch like that of the sun, and the shadow of the sun like that of a candle, when the difference is so considerable.

There is a third kind of shadow, neither produced by the sun nor a torch; but only a fine sunny day, which

wanting strength to finish and define its form, occasions a dimness near the object. Now for this there is no certain rule, but every body conducts it at discretion.

All these shadows, whether of the sun, torch, or daylight, must appear darker than the parts of objects not illuminated, and that part of the shadow most remote from the object must be darker than that nearer it. See CLARO-ORSCURO

SHAFT of a Column, in architecture, is the body of it, or the part contained between the capital and the base.

SHAFT of a Mine, the entrance or passage into it.

SHAGREEN, or CHAGREEN, a kind of grained leather imported from Constantinople, and the coast of Barbary, where it is said to be prepared from the skin of the hound fish, and is much used in covering cases for instruments, &c.

SHAMBLES, in mining, a term used to express a sort of niches, or landing-places, left at certain distances in the audits of mines.

The method of digging the tin mines in Devonshire, and some parts of Cornwall, is this: they sink their way in such a breadth, as is sufficient for them to stand and work, and at every fathom they leave a square place vacant, to which the ore is to be thrown up with shovels, as it is dug. This they do from cast to cast; that is, as far as a man can conveniently throw up the ore with his shovel. Thus the ore, as it is dug by the beelmen, is thrown up by the shovellers, who follow them from shamble to shamble, till it comes to the top of the mine. This, however, is but an inconvenient way, and the use of these shambles is generally supplied by a winder at the opening of the mine, which manages two buckets, the one of which is sent down empty, while the other is sent up full; and one man employed below to load, and another above to empty. *Phil. Trans. Num. 69.*

SHAMMY, or CHAMOIS Leather, a kind of leather dressed either in oil or tanned, and greatly esteemed for its softness, pliancy, and being capable of bearing soap without injury.

The true shammy is made from the skin of the chamois-goat, but is counterfeited with that of the common goat, kid, and even sheep-skins. The manner of preparing it is as follows.

The skins being washed, drained, and smeared over with quick-lime on the fleshy side, are folded in two, length-wise, the wool outwards, and laid on heaps, and so left to ferment eight days: or, if they had been left to dry after flaying, fifteen days.

Then they are washed out, drained, and half dried; laid on a wooden leg, or horse, the wool stripped off with a round staff for the purpose, and laid in a weak pit, the lime whereof had been used before, and had lost the greatest part of its force.

After twenty-four hours they are taken out, and left to drain twenty-four more; then put in another stronger pit. This done, they are taken out, drained, and put in again, by turns; which begins to dispose them to take oil: and this practice they continue for six weeks in summer, or three months in winter; at the end whereof they are washed out, laid on the wooden leg, and the surface of the skin on the wool-side peeled off, to render them the softer: then, made into parcels, steeped a night in the river, in winter more; stretched, six or seven over one another, on the wooden leg; and the knife passed strongly on the flesh-side, to take off any thing superfluous, and render the skin smooth.

Then they are stretched, as before, in the river; and the same operation repeated on the wool-side; then thrown into a tub of water with bran in it, which is brewed among the skins till the greatest part stick to them; and then separated into distinct tubs, till they swell, and rise of themselves above the water.

By this means, the remains of the lines are cleared out: they are then wrung out, hung up to dry on ropes, and sent to the mill, with the quantity of oil necessary to scour them: the best oil is that of stock-fish.

Here, they are first thrown in bundles into the river for twelve hours, then laid in the mill-trough and fullled without oil till they be well softened; then oiled with the hand, one by one, and thus formed into parcels of

four skins each, which are milled and dried on cords a second time, then a third: then oiled again and dried.

This process is repeated as often as necessity requires: when done, if there be any moisture remaining, they are dried in a stove, and made up into parcels wrapped up in wool: after some time they are opened to the air, but wrapped up again as before, till such time as the oil seems to have lost all its force, which it ordinarily does in twenty-four hours.

The skins are then returned from the mill to the chamoiser, to be scoured; which is done by putting them in a lixivium of wood-ashes, working and beating them in it with poles, and leaving them to steep till the lye have had its effect; then they are wrung out, steeped in another lixivium, wrung again, and this repeated till all the grease and oil be purged out. When this is done, they are half dried, and passed over a sharp-edged iron instrument, placed perpendicular in a block, which opens, softens, and makes them gentle: lastly, they are thoroughly dried, and passed over the same instrument again, which finishes the preparation, and leaves them in form of shammy.

Kid and goat skins are shammoised in the same manner as those of sheep; excepting that the hair is taken off, without the use of any lime; and that, when brought from the mill, they undergo a particular preparation, called ramalling; the most delicate and difficult of all the others.

It consists in this, that as soon as brought from the mill, they are steeped in a proper lixivium: taken out, stretched on a round wooden leg, and the hair scraped off with the knife; this makes them smooth, and in working casts a fine nap. The difficulty wholly consists in the scraping them evenly.

Explanation of Plate CXV. representing a mill for fulling the shammy.

Fig. 1. represents the mill drawn in perspective.

A B, is a vertical arbor carrying a horizontal wheel of forty-eight cogs. That vertical arbor is the center of motion, and is turned by the lever G, to which is fastened a spring-tree bar, for a horse.

The above wheel turns the lantern C, furnished with twenty rounds, and fixed upon the horizontal arbor CD, and elevated sufficiently for the horse to pass under it without the least obstruction.

At the extremity D of the above arbor is fixed a spur-wheel, furnished with forty-two cogs, and which turns the lantern E, furnished with twenty rounds. This lantern is fixed on the horizontal arbor E F. On this arbor the cranks 5, 6, &c. which raise the beetles or stampers 1, 2, 3, 4, &c. are fixed.

These beetles are supported in a strong cage of carpentry, as represented in the figure, and are suspended when not at work by the rolls a, b, on which the cords passing over the pulleys 8, 9, are wound, and the other end of them fastened to rings or staples fixed in the heads of the beetles.

The faces of these beetles are indented, and fall upon the skins placed in the troughs.

Fig. 2. is a plan of the mill, and exhibits more conspicuously the cranks which raise the beetles, 6, 7, 10, 5, 11, 12, 13.

The rollers a, b, are also here plainly represented. The other letters in this figure refer to the same parts, as the same letters in fig. 1.

SHANK, in the manege, signifies that part of a horse's fore-leg, which lies between the knee and the fetlock.

SHANKER, in medicine, a malignant ulcer, usually occasioned by the venereal disease.

Cockburn says any shanker may be cured with an ointment compounded of quicksilver and turpentine, without any further trouble, and Heister recommends the same method of practice.

SHARE of a Plough, that part which cuts the ground, the extremity forward being covered with a sharp-pointed iron called the point of the share; and the end of the wood behind the tail of the share.

The length of the whole share, from point to tail, according to Tull, should be three feet nine inches; at the top of the iron it has an upright piece called the fin, and,

near

near the iron at the other end, there is an oblong squared hollow, called the socket; the use of which is to receive the bottom of the sheat. Near the tail there is a thin plate of iron, well riveted to the wood; by means of this plate the tail of the share is held firmly to the hinder sheat of the plough by a small iron pin, with a skrew at the end, and a nut skrewed on it, on the inner or right side of the sheat.

The point of the share is that part in which it does not run up into the fin: this point is generally made of three inches and a half in length, and should be flat underneath, and round at the top, and the lower part of it must be of hard steel. The edge of the fin should also be well steeled, and should make an acute angle with the share.

The socket is a sort of mortise; it should be a foot long, and about two inches deep: the fore-end of it must not be perpendicular, but oblique, conformable to the end of the sheat which enters into it. The upper edge of the fore-part must be always made to bear against the sheat; but, if this end of the socket should not be quite so oblique as the sheat, it may be helped by paring off a small part of the wood at the point.

SHARK, in ichthyology, is the name of a very large fish, of which there are two species, distinguished by their different colours, blue and white.

The blue shark is a very terrible fish of prey; growing to seven or eight feet in length, and considerably thick in proportion; the mouth is capacious, and furnished with large broad teeth, some of them serrated at the edges.

The white shark is flat-backed, and is larger and has a greater number of teeth than the preceding, some of them weighing near a thousand pounds.

SHARP, in music, a kind of artificial semi-tone. See the article CHARACTER.

SHAW, a word used by our old writers, to signify a grove of trees.

SHEARING, or SHEERING, see the article SHEERING.

SHEAT of a Plough, that part of the plough which passes through the beam, and is fastened to the share.

The sheat, or as it is sometimes called the fore-sheat, there being another piece of timber behind it called the hinder sheat, should be seven inches wide, and fastened to the beam by a retch (a piece of iron with two legs) and by a wedge driven by it into the hole of the beam. The angle contained between the sheat and the beam of the plough should be about forty-two degrees.

SHEEP, *ovis*, in zoology, a well known species of cattle, and which are kept at the least expence of any to the farmer. They will thrive upon almost any ground, and for that reason are preferred by many before the larger cattle.

The best sort of sheep for fine wool are those bred in Herefordshire and Worcestershire, but they are small and black-faced, and bear but a small quantity.

Warwick, Leicestershire, Buckingham, and Northamptonshire breed a large-boned sheep, of the best shape, and deepest wool we have got. The marshes of Lincolnshire breed a very large kind of sheep, but their wool is not good, unless the breed be mended by bringing in sheep of other countries among them, which is a scheme of late very profitably followed there.

The northern counties in general breed sheep with long, but hairy wool: and Wales breeds a small hardy kind of sheep which has the best-tasted flesh, but the worst wool of all.

The farmer should always buy his sheep from a worse land than his own, and they should be big-boned, and have a long greasy wool, curling close and well. These sheep always breed the finest wool, and also are the most approved of by the butcher for sale in the market.

For the choice of sheep to breed, the ram must be young, and his skin of the same colour with his wool, for the lambs will be of the same colour with his skin. He should have a large long body, a broad forehead, round, and well rising, large eyes, and straight and short nostrils. The polled sheep, that is, those which have no horns, are found to be the best breeders. The ewe should have a broad back, a large bending neck,

small, but short; clean and nimble legs, and a thick deep wool covering her all over. To know whether they be sound or not, the farmer should examine the wool that none of it be wanting, and see that the gums be red, the teeth white and even, and the brisket skin red, the wool firm, the breath sweet, and the feet not hot. Two years old is the best time for beginning to breed, and their first lambs should not be kept too long, to weaken them by suckling, but be sold as soon as conveniently may be. They will breed advantageously, till they are seven years old.

The farmers have a method of knowing the age of a sheep, as a horse's is known, by the mouth. When a sheep is one shear, as they express it, it has two broad teeth before; when it is two shear, it will have four; when three, six; when four, eight; after this their mouths begin to break. The difference of land makes a very great difference in the sheep.

The fat pastures breed straight tall sheep, and the barren hills and downs breed square short ones; woods and mountains breed tall and slender sheep, but the best of all are those bred upon new plowed land, and dry grounds. On the contrary, all wet and moist lands are bad for sheep, especially such as are subject to be overflowed, and to have sand and dirt left on them. The salt marshes are, however, an exception to this general rule, for their saltness makes amends for their moisture; any thing of salt, by reason of its drying quality, being of great advantage to sheep.

As to the time of putting the rams to the ewes, the farmer must consider at what time of the spring his grass will be fit to maintain them and their lambs, and whether he has turneps to do it till the grass comes; for very often both the ewes and lambs are destroyed by the want of food; or, if this does not happen, if the lambs are only stunted in their growth by it, it is an accident that they never recover. The ewe goes twenty weeks with lamb, and according to this it is easy to calculate the proper time. The best time for them to year is in April, unless the owner has very forward grass, or turneps, or the sheep are field sheep, where you have not inclosures to keep them in, then it may be proper they should year in January, that the lambs may be strong by May-day, and be able to follow the dam over the fallows, and water furrows; but then the lambs that come so early, must have a great deal of care taken of them, and so indeed should all other lambs at their first falling, else, while they are weak, the crows and magpies will peck their eyes out.

When sheep are turned into fields of wheat or rye to feed, it must not be too rank first, for, if it be, it generally throws them into scowerings. Ewes that are big should be kept but bare, for it is very dangerous to them to be fat at the time of their bringing forth their young. They may be well fed indeed, like cows, a fortnight before-hand, to put them in heart. *Mortimer's Husbandry*.

The feeding sheep with turneps is one great advantage to the farmers, from the crops they raise of them: they soon fatten upon them, but there is some difficulty in getting them to feed on them; the old ones always refuse them at first, and will sometimes fast three or four days, till almost famished; but the young lambs fall to at once.

The common way, in some places, of turning a flock of sheep at large into a field of turneps, is very disadvantageous, for they will thus destroy as many in a fortnight, as would have kept them a whole winter. There are three other ways of feeding them on this food, all of which have their several advantages.

The first way is to divide the land by hurdles, and allow the sheep to come upon such a portion only at a time, as they can eat in one day, and so advance the hurdles farther into the ground daily, till all be eaten. This is infinitely better than the former random method, but they never eat them clean even this way, but leave the bottoms and outsides scooped in the ground; the people pull up these indeed with iron crooks, and lay them before the sheep again, but they are commonly so fouled with the creature's dung and urine, and with the dirt from their feet, that they do not care for them; they eat but

but little of them, and what they do, does not nourish them like the fresh roots.

The second way is by inclosing the sheep in hurdles, as in the former; but in this they pull up all the turneps they suppose the sheep can eat in one day, and daily remove the hurdles over the ground, whence they have pulled up the turneps: by this means there is no waste, and less expence, for a person may in two hours pull up all those turneps; the remaining shells of which would have employed three or four labourers a day to get up with their crooks out of the ground, trodden hard by the feet of the sheep; and the worst is, that as, in the method of pulling up first, the turneps are eat up clean; in this way, by the hook, they are wasted, the sheep do not eat any great part of them, and when the ground comes to be tilled afterwards for a crop of corn, the fragments of the turneps are seen in such quantities on the surface, that half the crop at least seems to have been wasted.

The third manner is to pull up the turneps, and remove them in a cart or waggon to some other place, spreading them on a fresh place every day; by this method the sheep will eat them up clean, both roots and leaves. The great advantage of this method is, when there is a land not far off which wants dung more than that where the turneps grow, which perhaps is also too wet for the sheep in winter, and then the turneps will, by the too great moisture and dirt of the soil, sometimes spoil the sheep, and give them the rot. Yet such ground will often bring forth more and larger turneps than dry land, and when they are carried off, and eaten by the sheep on plowed land in dry weather, and on green sward in wet weather, the sheep will succeed much the better; and the moist soil, where the turneps grow, not being trodden by the sheep, will be much fitter for a crop of corn, than if they had been fed with the turneps on it. The expence of hurdles, and the trouble of moving them is saved in this case, and this will counterbalance at least the expence of pulling the turneps, and carrying them to the places, where they are to be eaten. They must always be carried off for oxen. *Tull's Horse-hoeing Husbandry.*

SHEEP'S *Dung*, is one of the best manures we know. It succeeds better upon cold clayey lands, than any other dung whatever; but, as it is not so conveniently to be collected as the dung of larger animals, it is commonly conveyed to the land it is intended for, by folding the sheep upon it. The urine, as well as the dung, is thus given to the land, and is of very great advantage; but the farmer always should plow in this sort of manure as soon as he can, for the sun soon robs it of a great part of its virtue.

In Northamptonshire they begin to fold the sheep upon the lands that they would dung by them, after the month of July, and, the drier the lands are, the later they fold them. In Flanders they make many thousand loads of manure annually from their sheep: they cover the bottom of the folds considerably deep with some light and spongy earth, and, when this has received the dung and urine of the animals for seven or eight days, they remove it, and lay fresh in its place: the earth, thus impregnated, becomes an excellent improvement to land, and they raise large crops by means of it, in places where very little could be expected without it.

In England we have a contrivance like this, which is the covering the bottoms of the folds deep with sand, and changing it once in a week, or thereabouts: this is a kind of manure finely calculated for clayey lands, both the sand, and this peculiar kind of dung, being appropriated things for it.

SHEEP-NOSE *worms*, in natural history, a species of fly-worm, found in the noses of sheep, goats, and stags, and produced there from the egg of a large two-winged fly.

The frontal sinuses above the nose in sheep, and other animals, are the places where these worms live, and attain their full growth. These sinuses are always full of a soft white matter, which furnishes these worms with a proper nourishment, and are sufficiently large for their habitation; and when they have here acquired their destined growth, and come to the state in which they are fit to undergo their changes for the fly-state, they leave

their old habitation, and, falling to the earth, bury themselves there; and, when these are hatched into flies, the female, when she has been impregnated by the male, knows that the nose of a sheep, or other animal, is the only place for her to deposit her eggs, in order to their being hatched. *Reaumur's Hist. Insect.*

SHEERING, or SHEARING, in the woollen manufacture, implies the cutting off, with large sheers, the too long nap, in order to render the cloth more smooth and even.

SHEKEL, a coin in use among the ancient Jews, and worth two shillings and three-pence farthing sterling.

SHELF, among miners, implies the same with what they otherwise call soft ground, or fast country; being that part of the internal structure of the earth, which they find lying even, and in an orderly manner, and having evidently retained its primitive form and situation unmoved by the waters of the universal deluge, while the circumjacent and upper strata have plainly been removed from their original place.

SHELL, *Concha*, in natural history, a hard, and as it were stony covering, with which certain animals are defended, and thence called shell fish.

As to the formation of a shell, it is now generally allowed to be formed by a viscous fluid composed of glue, and several sandy particles of an exquisite fineness, which are transmitted through an infinite number of little channels to the pores where it transpires, condenses, and hardens. When the animal increases in bulk, and the extremity of her body is not sufficiently covered, it continues to evacuate and build in the same manner, finishing or repairing her habitation. This viscous matter is proved, by undeniable experiments, to arise from the body of animals, and not from the shell, as some have imagined. Those streaks and clouds which we observe most shells to be beautified with, proceed, probably, from the different disposition of the extreme parts of the animal's body that are visible at the aperture of the shell, where we may frequently discover some minute lobes or lines of flesh that differ from the rest in colour, containing, perhaps, different juices which may acquire a particular complexion in that place; and many other different causes may concur to paint, vein, and diversify the colours with a more or less lively glow. The quality of the food, the health or indisposition of the animal, the inequality of its constitution according to the several periods of her age, and the changes that may happen to the different perforation of her skin; in short, a thousand accidents may intervene, to heighten or diminish certain tints, and diversify the whole to infinity.

If the skill, in the variety of its colours, imitates the diversity of the animal's pores, it is still more apparent that it must assume the form of the body on which it is moulded. Thus we observe in all sea-shells, that if the animal has any swelling or inequality on its body, a tumor likewise rises in the corresponding part of the incrustation. When the creature displaces herself, and enlarges the dimensions of her dwelling, the same tumor which had already raised the shell in one part, swells it anew at a little distance, by which means you see the same species of inequality in a winding line round the shell. Sometimes these protuberances of the animal are so large, or so pointed, that those which rise them in the shell resemble horns. She afterwards fills the inside of these cavities; and then, by new evacuations of sweat, strikes out another set of horns, which protect her from such fishes as are fond of her flesh. If her body happens to be channelled, the shell that covers it has the same configuration: if the flesh rises in swellings winding round her in the form of a screw, the shell has likewise its elevations and depressions, carried on in a spiral line from her tail to the other extremity of her body.

Fossile SHELLS, those found buried at a great distance from the sea, in the bowels of the earth.

The number and variety of sea shells which are found far from seas buried at great depths in the earth, and often immersed in the hardest stones, is an object of great wonder.

Of these some are found remaining almost entirely in their native state, but others are variously altered by be-

ing impregnated with particles of stone, and of other fossils; in the place of others there is found mere stone or spar, or some other native mineral body, expressing all their lineaments in the greatest nicety, as being formed wholly from them, the shell having been first deposited in some solid matrix, and thence dissolved by very slow degrees, and this matter left in its place, on the cavities of stone and other solid substances, out of which shells have been dissolved and washed away, being afterwards filled up less slowly with these different substances, whether spar or whatever else: these substances, so filling the cavities, can necessarily be of no other form than that of the shell, to the absence of which the cavity was owing, though all the nicer lineaments may not be so exactly expressed. Besides these, we have, also, in many places, masses of stone formed within various shells; and these, having been received into the cavities of the shells while they were perfectly fluid, and having therefore nicely filled all their cavities, must retain the perfect figures of the internal part of the shell, when the shell itself should be worn away, or perished from their outside. The various species we find of these are, in many genera, as numerous as the known recent ones; and as we have in our own island not only the shells of our own shores, but those of many other very distant ones; so we have also many species, and those in great numbers, which are, in their recent state, the inhabitants of other yet unknown or unsearched seas and shores. The cockles, muscles, oysters, and the other common bivalves of our own seas are very abundant: but we have also an amazing number of the nautilus kind, particularly of the nautilus Græcorum, which, though a shell not found living in our own, or any neighbouring seas, yet is found buried in all our clay-pits about London, and else-where; and the most frequent of all fossil shells in some of our counties are the conchæ anomia, which yet we know not of in any part of the world in their recent state. Of this sort, also, are the cornua ammonis and the gryphitæ, with several of the echnatæ and others.

The exact similitude of the known shells recent and fossil, in their several kinds, will by no means suffer us to believe, that these, though not yet known to us in their living state, are, as some have idly thought, a sort of *lusus naturæ*. It is certain, that, of the many known shores, very few, not even those of our own island, have been yet carefully searched for the shell-fish that inhabit them; and, as we see in the nautilus Græcorum an instance of shells being brought from very distant parts of the world to be buried here, we cannot wonder that yet unknown shores, or the unknown bottom of deep seas should have furnished us with many unknown shell-fish, which may have been brought with the rest; whether that were at the time of the general deluge, or the effect of any other catastrophe of a like kind, or by whatever other means; to be left in the yet unhardened matter of our stony and clayey strata.

The vast beds of fossil shells, buried in many parts of the world, are not useless matter, but will serve to one of the greatest purposes of husbandry, the manuring of barren lands. The people of many parts of France, and in some places in our own country, dig up the masses of broken shells, connected into a sort of strata by marly, or other earths, for this purpose; and, spreading them upon the lands as dung, they soon moulder away, and are found extremely beneficial to the earth. Mr. Reaumur, desirous of knowing in what manner these fragments of shells fertilised land, at first conjectured that they did the same as the various species of marls, dissolving wholly away in time, and entering into, and fattening the earth; and carried it so far, as to believe that the common marls were a sort of earth, which owed its origin merely to such fragments of shells more perfectly dissolved; and consequently, that the rain and air, in some sort, converted these shells into marl upon the earth. But he was soon convinced of the error of this opinion, by the experience of the peasants, from whom he found that there was marl in the same pits whence they dug these shells, and that they used it also as manure, but to lands of a very different kind; those which received benefit from the marl being always injured by the shells, and, on the contrary, those which were meliorated by the

shells receiving no benefit from the marl. It might naturally enough be supposed that the salts, contained in these fossil shells, helped to fertilise the earth, in the same manner with the salts of the common sea plants, which are used as manure in many places. It is not impossible, but that the salts may indeed have their use in the whole, but the great good these shelly fragments do to the lands they are used on, is to be explained in a much easier manner, when the nature of the lands, on which they are employed, is considered.

These are usually cold clayey lands, on which nothing can grow but heath, and a few useless weeds, the common plants not shooting in any strength or perfection upon them; and they are always very wet upon the surface after any little rain, their texture being so close and compact, that the water cannot penetrate into them as it does into the spongy texture of the common fertile lands. This sort of manure, which is very light, and is no other than a mass of broken, and, as it were, half calcined shells, mixing with this earth, breaks its particles, and occasions a multitude of voids and little cavities in it, which reduce it to something like the common state of other earth, and the rain penetrates it as it does other mould.

The effects of this sort of manure are very lasting; a land well strewn with these shells is manured for twenty years, and the rain no longer wets its surface only, but penetrates its substance, and moistens the roots of plants sown in it. These find also an easier passage, and penetrate to a proper depth; while the plowman finds no less the benefit; his plough now easily turning up an earth, which before it was scarce able to cut. Some have imagined, indeed, that all these effects are owing to the salts in the shells operating in the manner of those of dung, and by that means breaking the connections of the more minute molecules; but ocular examination will shew the shells act, in this case, merely as particles of hard matter of that size and hardness, and do no more than fragments of stone of the same size would do; and the peasants are well acquainted with this, as they find it necessary to dung those lands, which they have before manured with shells, in the same manner as they do any others.

There are in many foreign countries, as well as in our own, lands of such a nature, that they never will become fertile, unless a large quantity of sand is dispersed over them. These lands are all of the same nature with those on which the farmers find their manure of shells to take effect. The sand, and this manure of shells, evidently act upon the same principle, in meliorating land, which is only by dividing its parts, when naturally too compact; but the shells are qualified to do it greatly the better of the two, because they are in themselves so considerably lighter. Somewhat analogous to this sort of manure is that of the throwing pebbles and rough fragments of stone on some earths, which are naturally tough and compact in a great degree. It is the general practice in husbandry to take off all the stones, as far as it can be done, from the lands: but these soils are apt to crack, and burst open in dry seasons, and the more stones are mixed with them, the less they are observed to crack, and what cracks they have are always the smaller and shorter. The earth is, by these stones, divided into so many separate parcels, that no very large and continued cracks can be formed; and always become the more fruitful the more stones it has upon it, provided they be not too large.

The manure of shells upon these lands, does not produce nearly so great an effect for the two first years, as it does in the succeeding ones: the reason of which is, that it is not at first sufficiently mixed, but in succeeding time it breaks itself into a number of very small particles, and these all become intimately blended with the molecules of the earth, and produce their effect more perfectly.

SHERIFF, an officer in each county of England, nominated by the king, invested with a judicial and ministerial power, and who takes place of every nobleman in the county, during the time of his office. His judicial authority consists in hearing and determining causes in his county court, and in keeping the peace of the county; he being by the common law the principal conserva-

tor of the peace there; for which reason he is to assist the justices, and raise the posse comitatus when occasion requires; and such persons, as on a hue and cry he shall apprehend upon suspicion of felony, he is to commit to prison; he may also imprison any one who breaks the peace in his presence. The ministerial office of the sheriff consists in proclaiming statutes, and making returns of writs for electing knights of the shire, &c. He collects the king's rents, seizes the profits of lands forfeited, and the goods of felons, levies the king's debts, fines, amercements, &c. and is accountable to the king for the profits of the county, on which account the sum of 4000 l. is set apart and annually allowed to the sheriffs of the several counties of England, to help them to pass their accounts, and to defray their expences at the assizes, &c. where no sheriff is obliged to keep a table for the entertainment of any persons but those of his own retinue; neither is he to have above forty servants in livery, or less than twenty attending him. It is also his office to execute the writs and processes out of the king's court; and no process is to be served but by the sheriff. He returns juries for trials, as well in civil as in criminal cases, except where there is cause of challenge against him, in which case they are to be returned by the coroner. And, lastly, the sheriff is to see that criminals are executed, and the order of law observed in putting them to death. A sheriff has usually under him an under-sheriff, bailiffs, and a goaler, for all of whom he is answerable. An under-sheriff ought always to have his deputy in the courts of justice, in order to receive their commands, and give an account of business, &c. All returns made by the under-sheriff are in the name of the high-sheriff; and for every default in the execution of his office, either by fraud or neglect, the high-sheriff is amerceable in the exchequer. On the death of any sheriff, the under-sheriff shall officiate in his name, till another is appointed, and also be answerable, &c.

SHIELD, a weapon of defence used by the ancients; it was in the form of a light buckler, and borne on the arm, in order to turn off the stroke of lances, darts, javelins, &c.

SHIELD, in heraldry, implies the escutcheon, or field, on which the bearings of coats of arms are placed.

SHILLING, an English silver coin, twenty of which are equal to a pound sterling. See **COIN**.

SHINGLES, among builders, are small pieces of wood, in the form of wedges, four or five inches broad, and eight or nine long. They are used instead of tiles or slates for covering the roofs, &c. of buildings.

SHINGLES, in medicine; see the article **HERPES**.

SHIP, a general name for all large vessels managed upon the sea by the assistance of sails and the helm.

A ship is known to be a great hollow machine composed of various parts and designed for various uses. The principal parts of which it is composed are the hull, masts, sails, and rigging: the principal ends for which it is formed are burden, passage, or war; so that the chief qualities required in the construction are capacity, velocity, and strength.

With regard to the invention and improvement of ships among the ancients, as well as their manner of equipping and conducting them; of arranging them in the order of battle and engaging in fight; of their sails and oars, their implements, and machines for war; we have already described these affairs at large in the articles **NAVAL Architecture**, **NAVAL Engagement**, and **NAVIGATION**.

A ship is navigated, or carried along, on the water by the action of the wind upon her sails, and the direction of her motion is governed by the effort of the helm, which acts upon her hind-part, like the tail of a fish.

The sails are expanded upon masts, to receive the current of wind; of these there are a great variety, according to the size of the ship, the place where she is built, or the force and direction of the wind. The form of sails are extremely different; but are generally either trapezias, or near the form of a square, or parallelogram, excepting stay sails and lateen sails, which are all usually triangular.

The masts are more or less in number, according to the size or figure of the ship, which also determines her name: and, as the effort of the wind on the sails strains the masts

considerably, it is necessary to support them by strong ropes, reaching from their tops to the ship's side, called shrouds; they are also sustained by other great ropes, from the fore part of the ship, called stays. See **MAST**, **SHROUDS**, **STAY**, and **SAILS**.

A mast, in large vessels, is usually composed of three pieces, the lower mast, the top-mast, and top-gallant-mast. See **MAST**.

Every ship has three masts, viz. the main-mast, fore-mast, and mizen-mast, besides the bowsprit. Each of these is furnished with three yards, viz. the lower yard, the top-sail-yard, and the top-gallant-yard. The bow-sprit has also two yards, viz. the sprit-sail and sprit-sail top-sail-yard. These are employed to extend the upper-edges of the sails. See **BOW-SPRIT** and **YARD**.

Amongst the variety of ships used in different countries, the principal are those of three masts, which are either known simply by the name of ships, which comprehends all the capital ones, or of galleons, galleasses, frigates, hag-boats, cats, fly-boats, barks, pinks, polacres, zebecks, which are all mentioned in their proper places.

Those of two masts are either snows, doggers, ketches, bilanders, brigs or brigantines, schooners, hermaphrodites, settees, gallies, barca-longas or shallops. See **SNOW**, **DOGGER**, &c.

And lastly those of one mast, are sloops, tartans, bean-cods, smacks, hoys, &c. All under this size are usually denominated boats. See the article **BOAT**.

With regard to the motion of a ship on the water, it is already treated of in the articles **NAVIGATION** and **SAILING**.

"A royal ship should appear noble, magnificent, and easy, in order to which, 1. She ought to stow or carry her stores, provision, ammunition completely. 2. She must be roomy for her number of men, to preserve their health, and make life comfortable, with apartments convenient for her officers, &c. 3. She should be easy at sea, and at anchor. 4. She should sail and work well." *O'Brien's Naval Evolutions*.

To illustrate what has been said on this subject, we have exhibited to our readers a representation of a first rate ship of war with all her masts, yards, and rigging, erect, and the several sails furled to their respective yards and stays.

Explanation of plate CXVI.

Parts of the hull.

- | | |
|-----------------------|-----------------------|
| A, the cat-head, | F, the hawse-holes, |
| B, the fore-chains, | G, the poop-lanterns, |
| C, the main-chains, | H, the cheff-tree, |
| D, the mizen-chains, | I, the head, |
| E, the entering-port, | K, the stern. |

Bowsprit and its rigging,

L, the bowsprit,

- | | |

|---------------------------------|----------------------------|
| 31, runner and tackle, | 42, jeers, |
| 32, 33, shrouds, | 43, yard-tackles, |
| 34, laniards, | 44, lifts, |
| 35, fore stay and laniard, | 45, braces and pendants, |
| 36, preventer-stay and laniard, | 46, sheets, |
| 37, woodings of the mast, | 47, tacks, |
| 38, fore-yard and sail, | 48, bow-lines and bridles, |
| 39, horses, | 49, fore bunt-lines, |
| 40, fore-top, | 50, fore leech-lines, |
| 41, crow-foot, | 51, fore-top rope, |
| | 52, futtock shrouds. |

O,

O, the fore-top-mast,

- | | |
|--------------------------|----------------------------|
| 53, 54, shrouds, | 62, horses, |
| 55, yard and sail, | 63, clue-lines, |
| 56, stay and sail, | 64, bow-lines and bridles, |
| 57, runner, | 65, reef-tackles, |
| 58, back-stays, | 66, sheets, |
| 59, haliards, | 67, bunt-lines, |
| 60, lifts, | 68, cross-trees, |
| 61, braces and pendants, | 69, cap. |

P, the fore-top-gallant-mast,

- | | |
|-------------------------------|--------------------------------|
| 70, 71, shrouds and laniards, | 77, braces and pendants, |
| 72, yard and sail, | 78, bow-lines and bridles, |
| 73, back-stays, | 79, flag-staff, |
| 74, stays, | 80, truck, |
| 75, lifts, | 81, flag-staff-stay, |
| 76, clue-lines, | 82, flag of lord high-admiral. |

Q, the main-mast,

- | | |
|----------------------------|-----------------------------|
| 83, 84, shrouds, | 96, lifts, |
| 85, laniards, | 97, braces and pendants, |
| 86, runner and tackle, | 98, horses, |
| 87, pendant of the garnet, | 99, sheets, |
| 88, guy of ditto, | 100, tacks, |
| 89, stay-sail, | 101, bow-lines and bridles, |
| 90, stay, | 102, crow-foot, |
| 91, preventer-stay, | 103, top-rope, |
| 92, stay-tackle, | 104, top, |
| 93, woodings of the mast, | 105, bunt-lines, |
| 94, jeers, | 106, leech-lines, |
| 95, yard-tackles, | 107, yard and sail. |

R, the main-top-mast,

- | | |
|---------------------------------------|-----------------------------|
| 108, 109, shrouds and laniards, | 117, lifts, |
| 110, yard and sail, | 118, clue-lines, |
| 111, futtock-shrouds, | 119, braces and pendants, |
| 112, back-stays, | 120, horses, |
| 113, stay, | 121, sheets, |
| 114, stay-sail and stay and haliards, | 122, bow-lines and bridles, |
| 115, runners, | 123, bunt-lines, |
| 116, haliards, | 124, reef-tackles, |
| | 125, cross-trees, |
| | 126, cap. |

S, the main-top-gallant-mast,

- | | |
|---------------------------------|-----------------------------|
| 127, 128, shrouds and laniards, | 134, braces and pendants, |
| 129, yard and sail, | 135, bow-lines and bridles, |
| 130, back-stays, | 136, clew-lines, |
| 131, stay, | 137, flag-staff, |
| 132, stay-sail and haliards, | 138, truck, |
| 133, lifts, | 139, flag-staff-stay, |
| | 140, flag-standard. |

T, the mizen-mast,

- | | |
|---------------------------------|-------------------------|
| 141, 142, shrouds and laniards, | 149, stay-sail, |
| 143, pendants and burtons, | 150, stay, |
| 144, yard and sail, | 151, derrick and span, |
| 145, crow-foot, | 152, top, |
| 146, sheet, | 153, cross-jack-yard, |
| 147, pendant-lines, | 154, cross-jack-lifts, |
| 148, peek-brails, | 155, cross-jack-braces, |
| | 156, cross-jack-slings. |

V, the mizzen-top-mast,

- | | |
|---------------------------------|-----------------------|
| 157, 158, shrouds and laniards, | 169, cross-trees, |
| 159, yard and sail, | 170, cap, |
| 160, back-stay, | 171, flag-staff, |
| 161, stay, | 172, flag-staff-stay, |
| 162, haliards, | 173, truck, |
| 163, lifts, | 174, flag-union, |
| 164, braces and pendants, | 175, ensign-staff, |
| 165, bow-lines and bridles, | 176, truck, |
| 166, sheets, | 177, ensign, |
| 167, clue-lines, | 178, poop-ladder. |
| 168, stay-sail, | 179, bower-cable. |

SHIP-BUILDING, the art of designing, constructing, and forming ships.

"It cannot be denied but that the art of ship-building, which is of so great an advantage to a state, is (although greatly improved) the most imperfect and most undetermined of all arts. The best builders have seldom any regard to other parts of a ship besides the two principal, viz. the head and stern; from hence it proceeds that the same builder, who builds two ships at the same time, and on

the same plan, often builds them so unequal, that we find their qualities extremely different.

"Chance has frequently so great a share in the construction, that we see ships, built with the greatest exactness and application, often prove the worst; and those which are built without any strict regard to rules, answer the purpose much better: so that the largest ships are sometimes the most defective; and we often find much better amongst the merchant ships, than amongst ships of war.

"It is true, that within these few years the French builders have endeavoured to bring their art to perfection. Some have begun by making plans, in which they have determined the several models, or draughts, of the fore and after parts of a ship; but as they want the necessary principles, they work with great uncertainty; their ships are not better than those which were built without the knowledge of reading and writing; neither sail better, nor bear so much sail, nor last so long. In a word, the builders in our days are of the same opinion with the ancients, that what agrees best with the sea, is yet undetermined.

"I doubt not several able builders have flattered themselves they have found in the practice of frequent and repeated essays, what they have not found in theory, but, I believe, they have been disappointed in the success; a ship is too complicated a machine, and there are too many things which must concur to render it complete, to leave its perfection to blind chance only. It very often happens in these cases, that when artists design to make their work complete, they spoil it, by endeavouring to rectify what before constituted its perfection: besides, the greater the essay or model, the greater will be the expence; and the smaller the model is formed, the more imperceptible will be the beauties or faults. We must however allow, that trials and experience are the beginning of all arts, when the works are yet but simple and undigested; but when they become more intricate or compounded, we must have recourse to theory, to develop that multitude of confused circumstances which perplex the artists, and lead them into numberless errors.

"I think the theory of ship-building ought to be reduced to the examination of three different articles: 1. Those which determine the figure of a ship. 2. Those which determine or contribute most to her solidity. 3. Those which best facilitate her plans." *L'Hoste's Theory of the Construction of a Ship.*

In the article NAVAL ARCHITECTURE, we have described the principal parts of a ship, and exhibited their disposition, and relation to each other in the plate thereto annexed. We shall here give some further account of the general rules observed in ship-building, and of the uniting those members so as to form a solid that shall possess the chief qualities for which the ship is designed.

Shipwrights, in delineating the models of ships, make use of three planes, which they call the sheer-plane, the floor-plane, and the body.

The sheer-plane is the same with that of elevation, being a section of a ship supposed to be cut by a plane passing through the middle line of the keel, stem, and stern-post. The floor-plane is the same with the horizontal, and is that on which the whole frame is erected. The body is the same with the profile; being a section supposed to cut the ship through the broadest place, and is perpendicular to the sheer and floor-planes.

The length of the keel, extreme breadth, depth in the hold, height between decks and in the waist, and sometimes the height of the wing transom, are agreed on by contract in the merchants service, from which dimensions the builder is to form a draught suitable to the trade the ship is designed for. The first thing that is generally done, is to lay down the keel, stem, and post, upon the sheer-planes: then to determine the proper station of the mid-ship timber, where a perpendicular is erected: it is generally about $\frac{2}{3}$ of the keel before the post. On this line the given depth of the hold is set off from the upper side of the keel; to obtain which point, the thickness of the timber and plank must be added to that agreed on by contract. This, being fixed, will enable us to determine the upper height of the extreme breadth at that place, which sometimes is the very point

point itself. The lower height of the breadth must likewise be determined at this place. Then we may form the two main heights of the breadth lines, which nearly unite abaft and afore. Abaft these curves end at the wing transom, or above it; and, afore, they are carried up sometimes as high as the hawse holes. The height of the breadth line of the top timber must likewise be formed. This is generally done by a bow, which makes nearly an arch of a circle. It is limited in midships by contract, afore and abaft only by the fancy and judgment of the artist, according to what sheer-plane he designs; we must also form a line for the rising of the floor; for which purpose we must determine the dead rising, which is that of the mid-ship timber. This limits it at that place, and, in the whole moulding, it is pretty near parallel to the lower height of the breadth lines. These lines must absolutely be drawn on the sheer-plane, and corresponding to the main and top timber height of breadth-lines; there must be two half breadth lines formed on the floor plane.

The main half breadth at the mid-ship timber is agreed on by contract, only observing that the thickness of the timber and plank must be deducted out of it, because it is the extreme breadth from outside to outside of the plank that is contracted for. Those in the draughts are called moulded half breadths. Then the breadth at the wing transom, if a square stern, is limited; it is generally about two thirds of the extreme breadth, but this is just as the artist shall think proper. He also fixes the breadth of the top timber, and then describes the two half breadth lines. In the due formation of these curves on the sheer and floor planes, the whole art of drawing chiefly consists, which must be acquired by practice, so that it will be scarce possible for one, that is not very well acquainted with drawing, to form them, without having recourse to some other draughts. After these are formed, the stations of the timbers are fixed; if the room and space, and the breadth of the midship timber, are agreed on by contract, this will determine the station of all the timbers; observing that the timbers abaft the mid-ships must be set off from the fore-side of the mid-ship timber; and the timbers before the midship from the aft side of it. At every third or fourth timber there must be perpendiculars drawn on the sheer and floor planes, to the line that represents the lower edge of the keel, which is the common section of these two planes; though sometimes the half breadth lines are described on the sheer plane, when there is not space to produce the perpendiculars till they be of sufficient length to contain the height of the breadth and half breadth.

After the timbers are stationed, and the perpendiculars for the frames drawn on the sheer and floor planes, we proceed to the body plane, and draw a line equal in length to the whole breadth moulded. This line may be called the base of the body plane. A perpendicular is erected at each end of it, and one in the middle, which may be produced at pleasure.

The next thing to be done, is to form the mid-ship frame; the limits of it are had from the sheer and floor planes; the lower, upper, and top timber heights of the breadth are taken from the sheer plane at the perpendicular, representing the midship frame, and set off on the middle line of the body plane from the base. Through these points, lines are drawn parallel to the base, and the respective half breadths, corresponding to each, are set off on these lines from the middle line in the body plane. The lower and upper main half breadths are limited by the perpendiculars already drawn at each end of the base. The half breadth of the top timber is had from the floor-plane on the perpendiculars representing the midship frame. The height of the dead rising is likewise taken from the sheer-plane, and set up from the base upon the middle line in the body-plane, through which point a line parallel to the base must be drawn, and upon this line the half breadth of the floor is set off from the middle line; at which point a perpendicular is erected. The center of the floor sweep is in this line, from which a circle must be described that shall just touch the rising line. A proper radius for the under breadth sweep is next to be found: the center of it is in the lower breadth line, from which

it is described to pass through the point which limits the half breadth. After which the radius, and center of a reconciling sweep to join the floor and under breadth sweeps, is found, and the circle described: and, to complete the frame below the breadth, the half breadth of the keel is set off from the middle line on the base; from which point, a straight line is drawn to touch the back of the floor sweep.

By this way of forming the frame, it is plain the centers and radii of the sweeps are arbitrary, but they must be determined before any of the other timbers can be formed; if by no other means, by repeated trials, till they are made to please the fancy and judgment of the artist. But there are various other ways of forming this frame; so that, though several ships may be of the same breadth, depth in the hold, and dead rising, they may all differ in the form of their timbers. After this midship timber is formed, a pattern or mould is made to fit exactly to the curve, and the dead rising line. By this, and a hollow mould, all the timbers are formed, so far as the rising line and lower height of the breadth line are parallel to one another in the sheer plane.

Having explained what the ship-wrights call whole moulding, we shall proceed to shew the method of forming the body by sweeps.

In ships of war the general dimensions are established by the authority of those appointed by the government for that purpose. The sheer and floor planes are laid down in this, exactly in the same manner as in that of the whole moulding. We may have a sufficient number of points from the dimensions settled by authority to determine the heights of the breadth and half breadth lines. A rising of the floor line must likewise be formed on the sheer draught. We may then go to the body plane, and form the midship bend or frame timber; the limits of which we have from the sheer and floor planes, and it must be formed in the same manner as before directed in whole moulding, either by two, three, or more sweeps, as the artists shall think most suitable to the service the ship is designed for. The lower, upper, and top timber heights of breadth, and risings of the floor are set up on the middle line in the body plane, as in whole moulding, and lines drawn through these points parallel to the base upon which the half breadths are set off. A mould may then be made for the midship frame as before, and laid upon the several risings in the same manner as in whole moulding, with this difference, that here an under breadth sweep is described to pass through the point which limits the half breadth of the timber; the center of which will be in the breadth line of that timber. The proper centers for all the frames being found, and the arches described, the bend mould must be so placed on the rising line of the floor, that the back of it may touch the back of the under breadth sweep. But the general practice is to describe all the floor sweeps with compasses as well as the under-breadth sweeps, and to reconcile these two by a mould which is an arch of a circle; its radius being the same with that of the reconciling sweep, by which the midship frame was formed. It is usual for all the floor sweeps to be of one radius; and, in order to find their centers, a line is formed on the floor plane for the half breadth of the floor: this, as was before observed, is only an imaginary one; for it cannot be described on the surface of the ship: instead of it some make use of a diagonal in the body plane, to limit the half breadth of the floor upon every rising line, and erect perpendiculars at the several intersections in the same manner as for the midship frame, as in the draught; where it is very plain the floor sweep constitutes no part of the after timbers abaft the square body. After the sweeps are all described, we must have recourse to moulds, or some such contrivance, to form the hollow of the timbers, much in the same manner as in whole moulding; and, when we have thus formed all the timbers, they must be proved by ribband and water-lines, as before directed; and altered, if needful, to make these lines fair; hence it is obvious, that the form of the ribband lines must be determined, before we can with certainty have the true form of the timbers. But there will be a necessity of determining at least, the form of three timbers, viz. the midship, foremast, and aftermost, before

Fig. 1. Ship building

before we can form a ribband line. These will give three points, through which the curve of each ribband must pass. The points in the intermediate timbers may be found by forming timbers as before directed; but by repeated trials, altering them till they make fair ribbands; for it is by them that the whole structure is regulated, when every frame is erected into its proper place.

The general dimensions being determined, and a scale adapted to the draught, take the half breadth with a pair of compasses, and placing one foot in the proper point for the half breadth of $\oplus$, which will be found in number V. open the sector till the other foot reaches to the same point in the corresponding line on the other leg. See the article SHIPWRIGHTS-Sector.

The sector being thus set, it will be indifferent whether we begin with the body or sheer plane: let it then be the sheer.

First, draw the line XZ (plate CXVII.) to represent the upper edge of the keel, and length of the gun-deck; but it may be produced to the aft side of the wing transom, and fore part of the stem.

Secondly, erect a perpendicular to the line XZ, upon which set up the heights of the wing transom to W; taken from N^o. IV. on the sector.

Thirdly, take the rake of the post from number VII. on the sector, and set it forward from the perpendicular of the wing transom to the point 7, where a perpendicular must be erected, which will be the station of that timber.

Fourthly, take the distance of the frames from number III. on the sector, and set it off from 7 to 8; and erect a perpendicular at that point for timber 8. Draw also a line from 8 to the wing transom, to represent the fore-part of the post.

Fifthly, take the height and rake of both counters, also the rake of the stern timber, from number II. The height of the stern timber is on number I. and by these form the counters, and upright of the stern.

Sixthly, station the timbers, by taking the distance between the perpendiculars at 7 and 8; which at eight times will reach to $\oplus$; and erect perpendiculars at 5, 3, and $\oplus$. Then, for stationing the timbers in the fore-body, we must turn the sector, and take the distance of the frames from number III. which, set eight times from $\oplus$, will reach to H. Erect perpendiculars at C, E, G, and H; and from G set off the distance of the gun-deck before G. It is in number I. on the sector, which will reach to Z; at which point erect a perpendicular, and set off the height of the gun-deck, taken from the sector; and from the gun-deck set up the height of the head of the stem, also its distance before G; both taken from number I. We may then form the stem. The center of the sweep is in the perpendicular of timber F, and the radius of the sweep is upon the sector between numbers III. and IV. which, set up from the point F, will give the center: so the sweep will just touch the upper edge of the keel in the point F. And, as the sweep will not reach to the gun-deck, we must make use of a mould to break in fair with the back of the sweep.

Seventhly, set up the heights of the lower, upper, and top timber breadth lines upon the perpendiculars erected for the stations of the several timbers. The points, corresponding to each, are on their proper lines on the sector.

Having thus finished the sheer plane, we may then go to the floor plane: and, producing all the perpendiculars for the timbers, we may upon them set off the main and top timber half breadths. The points corresponding to each are on their proper lines upon the sector; which must be set off from the line WK, representing the lower side of the keel, and may be produced both ways, as far as shall be needful. We must in the next place form all the ribband lines, which are the dotted ones in the draught; beginning with the fourth ribband. But it will be more expeditious, first, to draw all the diagonals in the body plane.

Let AB be the whole breadth, on the middle of which erect the perpendicular KO; so shall AK, or KB, be the half breadth. Upon the line KO, set up the several heights of the breadth lines, taken from the sheer plane, and draw lines parallel to the base, as has been already directed; and likewise set off the half

breadths corresponding to each, taken from the floor plane. We may also set off the height and half breadth of the wing transom; all which may be done without the sector; but we must have recourse to it for the dead rising. This is in number III. in the after body, and must be set off upon the line KO, from the lower height of breadth to i . Through i draw the line $r i s$, parallel to the base, and set off the one half breadth of the floor from i to r , and from i to s ; it is upon number VII. on the sector. Then, taking $r i$, set it up from i upon the line KO, to which point draw the dotted diagonal marked R 1st. This regulates all the other diagonals: for, if one line be drawn from the point of this intersection, with the middle line, to the half breadth of the wing transom; and another from the point r , its intersecting with the rising line, to the point $\oplus$, at the lower height of breadth; each of these may be divided into four equal parts by the dotted diagonals $2^d R^d$, $3^d R^d$, $4^d R^d$.

Note, the lines from the ends of the first diagonal to the lower height of breadth, and to the wing transom, were drawn only with a black lead pencil, and wiped out after the diagonals were drawn. The diagonals being thus drawn, we may form the midship frame, for which purpose we must find a point in each diagonal, through which the curve of the timber must pass. These points we have from the sector; which must be set off from the intersections of the diagonals with the line KO. That in the first diagonal is in number I. The point in the second diagonal is in number VI. The point in the third diagonal is in number V. And the point in the fourth diagonal is between numbers I and II. This last must be doubled, because the sector will not contain the whole length. The midship frame being formed, we must in the next place form the after and foremost timber; which the sector does, by giving the distance on every diagonal between these timbers, and the midship frame now formed: so that we shall have a point in each diagonal, through which the curve of the timber must pass. To find the point in the first diagonal for the after timber, extend 1st, from $\oplus R$ in number V. to the corresponding point on the other leg. Set off this distance from $\oplus$ on the first diagonal: do the same upon the second, third, and fourth diagonals. The point on the second diagonal is in number IV. That on the third in number VI. And that on the fourth in number VII. The curve must pass through these points, and likewise through the point for the half breadth, which was before set off from the sheer and floor planes; by which means we have determined the form of the after timber; and the foremost timber is to be formed by the same method. These two timbers being formed, we may find points in the diagonals for all the intermediate timbers. Thus, to find the point for timber 3 in the first diagonal, extend from the point 3 in the inner part of the line number V. to its corresponding point on the other leg. Set off this in the first diagonal from the after timber, already formed; which will give the point through which timber 3 must pass; and, to find the point in the second diagonal, we must extend from 3, in the inner part of the line number IV. and set off this distance in the second diagonal from the after timber. The same method must be used to find the points in the third and fourth diagonals. In like manner we may find a point in each diagonal for the timbers 5 and 7, which will be sufficient for the after body: and the same process must be used to find points in each diagonal for the timbers in the fore body.

Having now found the points, before we form the timbers, it may be proper, by them, to form the ribbands: for now we may take the distance of each point in the diagonal, from its intersection with the middle line KO, and transfer it to the floor plane upon the perpendiculars that represent the planes of the timbers, as before directed. In order to limit the ends of the ribband lines on the floor plane, we must set off half the thickness of the post, on one side of the middle line KO, and half the thickness of the stem on the other side of it, on the body plane; first deducting the depth of the rabbet out of it. We must likewise determine the inner part of the rabbet on the stem, and upon the post in the sheer plane. In the stem, it is generally in the middle between the lines that represent the outside of the rabbet. It may be

also so on the post, from the wing to the lower transom; and from thence the line may be continued fair to intersect the line that represents the after side of the rabbet, at the upper edge of the keel; for there the rabbet is cut square into the post.

Now it is obvious that, when the plane of any diagonal ribband is in its proper place and position, the line *W K* will be in the sheer plane, parallel to the upper side of the keel; and its height will be the same with that of the point where the diagonal intersects the middle line in the body plane. But by reason of its inclination, and of the half thickness of the stem and post, the height of the plane of the ribband upon the post and stem will be in the point where the diagonal intersects the line that represents the rabbet in the body plane. This then must be transferred from the body to the sheer plane, and set up from the upper edge of the keel upon a perpendicular that will intersect the line that represents the inside of the rabbet at that height. This perpendicular may be produced into the floor plane; and, if that part of the diagonal intercepted between the middle line, and the line that represents the inside of the rabbet, in the body plane, be set off upon the perpendicular, it will give the proper point for the end of the ribband line, as may be seen in the plate; where all the ribbands are dotted lines, and they are marked 1st *DR*, 2d *DR*, &c.

Note, the scale in the plate is so small, that we have taken the outside of the rabbet to limit the end of the ribband.

The ribbands being thus formed, we may from them form all the timbers below the breadth.

The next thing to be done, is to form the top timbers. We have the height and half breadth of each from the sheer and floor planes; and the timbers below the breadth are carried up by a sweep, which forms the lower part of the top timber. The center of this sweep is in the upper height of the breadth line of the timber, and may be taken from the sector: it is on number III. after body. The midship top timber has generally a hollow, which is left intirely to the artist; for some, especially small ships, have none. The general practice is to make a mould for this hollow, either by a sweep, or some other contrivance, and produce it considerably above the height of the top timber in a straight line, or very near one. The midship timber is formed by this mould, and so placed, that it breaks in fair with the back of the upper breadth sweep. All the other timbers are likewise formed by the same mould; observing to place it so that the straight part of it may be parallel to the straight part of the midship timber; and moved up or down in that direction till it just touches the back of the upper breadth sweep. Some begin at the after timber after the mould is made for the midship one, because they think it easier keeping the straight part of the mould parallel to this, than to the midship timber; and by this means the top side is kept from winding. Others again make a mark upon the mould where the breadth line of the midship timber crosses it, and with the same mould they form the after timber. This will occasion the mark that was made on the mould, when in midships, to fall below the breadth line of the after timber; and so another mark is made at the height of the breadth of the after timber.

The next thing to be done, is to lay the straight part of the mould obliquely across the breadth lines of the top timbers in such a manner that it may intersect the breadth line of the midship timber at one of these marks, and the breadth line of the after timber at the other mark. Then the several intersections of the breadth lines of the timbers are marked upon the mould. The mould, being thus marked, must be so placed in forming each timber, that the proper mark may be applied to its proper breadth; and the mould be turned about so as just to sweep the upper breadth sweep. Any of these methods may make a fair side; but it may be easily proved by forming another half breadth line.

Hitherto, we have considered the timbers, as having their planes perpendicular both to the sheer and floor planes. These are called square timbers: and, when they are all formed, we may from them form as many ribband and water lines as shall be necessary to form the cant timbers. Their planes are inclined to the sheer,

but perpendicular to the floor planes. The reason of canting these timbers is, that they may nearly be equally spaced at the breadth ribband: for, if the post has a considerable rake, and the timbers all square, there will be a great space at the breadth ribband, between timber 8 and the wing transom: besides, the timber may be so canted, that it may be square to some of the ribbands; whereas, if they were perpendicular to the sheer plane, they would intersect the ribband lines so as to form very oblique angles; which would occasion very great beveling. Another advantage that attends canting the timbers, is, that they will not require such compass timber.

It is usual to begin the cant timbers from the aftermost floor timber, and space them near equally on the breadth line to the wing transom: and, in order to space them upon the keel, the cant of the fashion piece must be determined. Now, if we suppose the plane of the fashion piece to intersect the sheer and floor planes in the point *F*, it must intersect the floor plane in the line *F P*, because the point *P* is supposed to be the end of the wing transom. So the angle *F P* will be its inclination to the sheer plane. It will intersect the sheer plane in a perpendicular erected from the point *F*; and, if the space between the point *F* and the foremost cant timber upon the keel, be divided into the same number of equal parts, that the space between the same timber, and the wing transom upon the breadth line, is divided into; this will determine the cant of all the timbers, only by drawing lines from all points in the line *W K*, to the corresponding points in the breadth line, in the same manner as the line *F P* determines the cant of the fashion piece.

It would be needless to draw all these lines in the plate, the only intent of drawing them being to shew how to form the timbers by them: and as one method serves for all the cant timbers, which are supposed perpendicular to the floor plane, it will be sufficient to shew the formation of the fashion piece. Before any of the cant timbers can be formed, there must be a sufficient number of water lines, or diagonal and horizontal ribband lines, formed from the square timbers: and, when these are absolutely determined, we may, with certainty, form all the cant timbers, either by water or ribband lines.

If we make use of the diagonal ribbands, which are distinguished by the dotted curves in the floor plane, we must form an horizontal ribband corresponding to each. We have only laid down one of these horizontals in the plate, viz. that corresponding to the third diagonal: it is marked 3^d *HR*. To form this ribband, fix one foot of the compasses in the point where the third diagonal intersects the midship frame in the body plane; and extend the other foot to touch the middle line *K O*; so that, if a line were drawn from one foot of the compasses to the other, it would be perpendicular to the line *K O*: this distance set off from the line *W K*, upon the perpendicular that represents $\oplus$ in the floor-plane, will give the point thro' which the curve must pass at that place. The same method must be used for finding the points on all the other timbers.

Now, though the diagonal and horizontal ribbands seem to be quite different curves in the plates, they will make but one line upon the timbers; for the one intersects them in a direction perpendicular to the sheer plane, and the other is so inclined as to intersect the timbers in the very same points. The horizontal one is too short upon the plate, but the true length of it might easily be had by transferring to the sheer plane the several heights at which the diagonal intersects the timbers in the body plane. By these we might form a height of breadth line to correspond to this horizontal ribband, which is only a half breadth line; and the length of this height of breadth line may be taken by a penning batten, and all the timbers marked upon it. Now, when the batten is applied to a straight line, and all the timbers transferred to this line from the batten, we may erect perpendiculars at each, and set off the same half breadths as before; by which means we may have the true length of the horizontal ribband: but, as this will be of no manner of service, we shall omit forming it. We only mention it, because several imagine these two curves to be as different

on the surface of the ship as they are upon the draught. The horizontal ribband corresponding to the first diagonal one is formed to timber 7, and marked 1st H R; but the horizontals for the second and fourth diagonals were formed by a black-lead pencil, and only the point in which they intersect the line F P, is in the plate; which is sufficient for our purpose.

There are likewise five water lines formed, four of which are represented by level lines in the body plane, and by lines parallel to the keel in the sheer plane: three of them represent the planes of the transoms in the sheer plane, viz. D^k. 1st, 2^d: but the plane of the third transom is perpendicular to the post. The lower water line is drawn parallel to the keel from the stem to the post, and produced into the body plane, as in the plate, where it is marked M N: the plane of the third transom intersects the timbers at different heights, which are transferred from the sheer to the body plane, where it forms a curve.

The water lines being now drawn in the sheer and body plane, our next business is to form them in the floor plane, where they will be curves. The points through which the curve of the lower water line is to pass, are had by transferring the several portions of the level line, intercepted between the line K O, and the curve of each timber, from the body plane to the corresponding perpendiculars in the floor plane, where it is marked *Wat* L. It must be observed that the line K O, in the body plane, represents the several perpendiculars that are drawn in the sheer plane to represent the planes of the timbers: for the spaces in the body plane, contained between the line K O and the curves of each timber, are so many different planes; and, when in their proper places, they will be parallel to one another, if perpendicular to the sheer and floor planes. Thus the plane contained between the line K O, and the curve of timber $\oplus$ is (when in its proper place) supposed to be erected perpendicular to the sheer plane, in the line which represents the plane of $\oplus$; and the like may be said of all the rest. The planes of the cant timbers will not be parallel to one another, because they are differently inclined to the sheer plane; but, as they are perpendicular to the floor plane, they will intersect the sheer plane in a line perpendicular to the keel: so the plane of the fashion piece intersects the sheer plane in the dotted perpendicular, erected from the point F, which is the same with the line K O, in the body plane. We thought it necessary to take notice of this, because some who are learning to draw, mistake the line K O; for they imagine it only represents the post or stem.

Another error which they frequently fall into, is about forming the water lines when their planes are not parallel to the keel. They imagine that the half breadths must be set off from the line W K, which represents the lower edge of the keel; whereas it is indifferent what straight line they are set off from, so the timbers be exactly spaced, and perpendiculars drawn to represent their planes. Now, when the water lines are supposed parallel to the keel, the timbers are properly spaced, and the perpendiculars ready drawn to the line W K; which is the reason it is used in such cases: tho' when the plane is in its true place, the line W K will be in the line M N. But the case will be quite different when the water lines are not parallel to the keel; for then their planes will intersect the sheer plane in a straight line, forming oblique angles with the planes of the timbers; this is the case in the plane of the third transom. The distances between the timbers will be more in this line than in the line W K; so the half breadths cannot be set off from the line W K, upon the perpendiculars that represent the planes of the timbers, unless they be properly spaced at the same distance they are upon the line that represents the plane of the third transom in the sheer plane; upon which account we have made use of that line to set off the half breadths from, and drawn the dotted perpendiculars at the points where it intersects the planes of the timbers 8, 7, and at the point where it intersects the lower height of the breadth line. The heights of the points of intersection are transferred from the sheer to the body plane; and the half breadths, at these heights, transferred from the body plane to the dotted perpendiculars before drawn: the half breadth to be set off upon the perpendicular where it intersects the lower height of the breadth line, is had from the floor plane,

and the dotted perpendicular *aa* will shew the place where the half breadth must be taken: this perpendicular, if produced, will intersect the plane of the third transom in the lower height of the breadth.

Having now formed four diagonal ribbands with their corresponding horizontals, and also two water lines; we may by these form the fashion piece, either upon the body plane or sheer plane; but, as the plane of the fashion piece is parallel to neither of these, it will require two operations.

Now the line F P will intersect all the ribband and water lines; but, because the diagonal ribbands are not in their proper position, the line F P will not intersect them in the point where the plane of the fashion piece intersects them.

The first thing then to be done, is to find the true place of the fashion piece on each diagonal ribband: and first, to find its place upon the fourth diagonal ribband, from the point *t*, where the fourth horizontal ribband intersects the line F P, let fall a perpendicular to the point *s*, and produce it to intersect the diagonal ribband in *r*; so shall *r* be the true place of the fashion piece upon that ribband; that part of the perpendicular between *t* and *s* is not drawn in the plate, to avoid the confusion of too many lines. The reason of this will be very evident, if we suppose the whole plane of the ribband to be turned round upon the axis W K; for then the point *r* will always be right over some point of the perpendicular *rt*; and, when the ribband is in its proper inclination, a perpendicular from *r* will fall into the point *t*, and the plane of the fashion piece will intersect the floor plane in the line *t* F, and the plane of the diagonal ribband in a straight line drawn from *r* to F: for it must be observed, that when the ribband is in its proper place, the line W K will be in the sheer plane, in a line parallel to the keel; the height of which may be had from the body plane. In this case it will be the distance between K and *r*, but it will be needless to draw this line in the plate.

Having now found the place of the fashion piece on the fourth diagonal ribband, we must by the same method find its place on the other diagonals, as in the plate, where lines perpendicular to W K are drawn to the points *o, o, o*, in the diagonal ribbands, from the points where the line F P intersects the corresponding horizontal ribbands.

These points being now found, we may take the nearest distance of each point to the line W K, and set off those distances on the proper diagonals in the body plane. Thus, for the fourth ribband, place one foot of the compasses in the point *r*, and the other in the point *s* in the floor plane; and set off that distance from *r* to *S*, on the fourth diagonal in the body plane: do the same by all the rest of the diagonals; and a curve intersecting the diagonals in these points would be the projection of the fashion piece in the body plane, but we have not drawn this in the plate; for, as the plane of the fashion piece is not parallel to that of the body plane, its projection will be less than the original: however, this may be found by the following method:

First, draw a perpendicular to the line K O, in the body plane, to pass through the point *S* to F.

Second, take the distance from *r* to F, in the floor plane, and set it off from *r* to F, in the body plane. In like manner draw perpendiculars to the line K O, in the body plane, through the points before found on the diagonals, as in the plate, where only that part of the perpendicular is drawn which lies without the diagonal; and take the several distances between the points *o* and F, in the floor plane, and set them off from the intersections of their corresponding diagonals, with the line K O, to the points *o, o*, in the body plane: so we have the points *o, o, F*, through which the curve must pass.

Thirdly, to find the point P in the body plane, thro' which the curve must pass, transfer the point P in the floor plane, to the point P, in the sheer plane, by a perpendicular to the line W K, to intersect the height of breadth line in the point P; and set off this height upon the line K O, in the body plane, which will be a little above W, the height of the wing transom: draw a perpendicular at this point, to the line K O, take the line F F, in the floor plane, and set it off upon this perpendicular, from

from the line K O, to the point P: so shall the curve P F be the form of the fashion piece.

These points may all be found without the diagonal ribbands, by half breadth lines and water lines, formed on the floor plane; as, for instance, to find the point F, place one foot of the compasses in *t*, the point where the horizontal ribband intersects the plane of the fashion piece, and the other in *s*; *t s* being perpendicular to W K: with that extent, move the compasses with one point in the line K O, and the other point perpendicular to it, till it intersect the fourth diagonal, in the point S; through which draw the perpendicular *t F*. Then take the distance from *t* to F, in the floor plane, which set off from *t* to F in the body plane; so shall F be the point required, as before: in like manner the points *o o*, may be found: but this, as well as the other method, requires two operations; whereas, if several water lines were formed, with their planes parallel to the keel, we might find the points by one operation.

Thus, suppose it was required to find a point in the level line, that represents the plane of the water line formed in the floor plane, which is marked *Wat L*, fix one foot of the compasses in the point *f*, where the line F P intersects the water line in the floor plane, and the other foot in the point F. Set off this upon the level line in the body plane, from the line K O to *f*, which will be the point required. All the other cant timbers, both in the fore and after body, are formed after the same manner as the fashion piece. We have formed but one more in the plate, which is abaft the fashion piece, to assist us in forming the transoms.

The transoms are fastened to the stern post, in the same manner that the floor timbers are to the keel; and, as the floor timbers have a rising, so likewise have the transoms, which is called the flight; and besides this flight, the wing transom has a round aft, and a round up, both which are arbitrary: the deck transom has a round up, the same with that of the beams: but, in forming the transoms, there is no regard had to the round up; for that may be done by the beam mould, after the transom is properly hewed the moulding way.

In forming the transoms, the first thing to be done, is to assign each its proper place upon the post, and then to determine the position of their planes with respect to the floor plane; for their planes are always perpendicular to the sheer plane. In the plate there are five transoms: their upper sides upon the post are in the points W, D^k, 1st, 2^d, 3^d: the planes of the wing, deck, first and second transoms, are supposed parallel to the floor plane, and represented in the sheer plane by lines drawn parallel to the keel from the post, till they intersect the lower height of the breadth line; and the plane of the third is represented by a line perpendicular to the post, as in the plate. So it will not be parallel to the floor plane.

The height and position of the transoms being determined, we have no more to do, but to form water lines for each. That for the third we have already formed: the rest, being supposed parallel to the floor plane, may be formed in the same manner as the water line there laid down: the only difficulty will be to find a sufficient number of points to determine their forms; because, in the deck and first transoms, their planes intersect the breadth; so that we could only have a point in timber 8, if the fashion piece and a timber abaft it had not been formed by the ribbands; but, now they are formed, we may have likewise a point in each of their planes, thro' which the curves of the water lines shall pass.

We shall begin with the wing transom. First, determine the round aft, which suppose the line W T, in the floor plane: take its height from the sheer plane, and set it up in the body plane from K to W, and draw the line W T: then take this line W T, and set it off on the floor plane, on the line F P, which will reach to the point *n*. A curve drawn through the point *n*, to break in fair with the breadth line, as in the plate, will intersect the line W T in T; so shall W T *n* be the aft side of the wing transom. Next, for the deck transom, draw a level line in the body plane at the point D to timber 8. Set off this distance upon timber 8, in the floor plane, from the line W K; which will give us a point through which the curve must pass; then take the distance in the

level line, between the line K O and the curve of the fashion piece: which set off from the point F, upon the line F P in the floor plane; and this will give another point thro' which the curve must pass: again, take the distance in the same level line, between the line K O and the curve of the timber abaft the fashion piece; which set off from the point G upon the line G g, in the floor plane; and we shall have a third point through which the curve must pass. Lastly, let fall a perpendicular to the line W K, from the point D^k upon the post, and produce it into the floor plane, upon which set off half the thickness of the post, allowing for the rabbet, which will limit the end of the water line that forms the deck transom. After the same manner are the first and second transoms formed, by drawing level lines in the body plane, at their heights upon the line K O.

Now some are apt to mistake these level lines for the lengths of the transoms: the reason, as was before observed, is because they imagine the line K O to be the stern post; whereas it is the perpendicular in which the plane of the fashion piece intersects the sheer plane; and so these lines are drawn upon the plane of the fashion piece.

All that now remains, is to determine the length of each transom; and this is done by the line F P, in the floor plane, which intersects the wing, deck, first and second transoms, to their proper lengths. But, before we can find the length of the third, the plane of the fashion piece must be projected upon the sheer plane: thus, take the nearest distance between any perpendicular in the floor plane, and the point where the line F P intersects the water line; and set that off from the same perpendicular upon the line that represents the same water line in the sheer plane. Now the curve P F will be found to be the projection of the aft side of the fashion piece upon the sheer plane: for the distance between the perpendicular of timber 8, and the point *f*, where the line F P intersects the lower water line in the floor plane, is equal to the distance between the same perpendicular and the curve P F, taken in the line M N. The distance between the perpendicular of timber 8, and the point where the line F P intersects the second water line in the floor plane, is equal to the distance between the same perpendicular and the curve P F, taken in the line that represents the second transom in the sheer plane. And by the same method, we find points in the lines that represent the deck and first transoms. The point P is transferred from the half breadth line in the floor plane, to the height of the breadth line in the sheer plane. The curve, being thus drawn, will intersect the line that represents the plane of the third transom, in the point *z*: from which point draw the perpendicular *z F*, to the curve of the dotted water line; so shall *z F*, be the true form of the third transom: and a line drawn from F to P will be the plane of the fashion piece. It must be observed that the ends of the transoms are let into the fashion piece; for which there must be a proper allowance left without the lengths found by the line F P. We have in the plate only laid down the half of each transom. Those who incline to lay down the whole transoms, may easily transfer the halves already described to the other side of the line W F.

Having now formed all the timbers, both square and cant, in the after body, we shall proceed to the fore body. The cant timbers are laid down in the same manner as those in the after body, by the diagonal and horizontal ribbands; where the dotted line K T represents the plane of the knuckle timber, canted upon the floor plane; from whence it is transferred to the body plane, and represented by the dotted curve between the timber H and G.

The hawse pieces are seldom laid down in the loft; it being the general practice to make moulds for them after the other timbers are put up, and the harpins are brought about.

As the harpins are levelled across, they will be formed by the section of a plane perpendicular to the sheer plane: but there is no necessity for these sections to be parallel to the keel. In the plate we have drawn only a straight line to represent the plane of the harpin above the wale. It is drawn from the stem to the timber E, and marked harpin.

A First Rate Ship of War, with Rigging &c.

harpin. Now, in order to form the curve of this harpin, it would be proper to form timber F, in the body plane: also to draw perpendiculars to the several points where the plane of the harpin intersects the planes of the timbers E, F, G, and H, in the sheer plane; and upon these to set off the half breadths corresponding to each, taken from the body plane. This would give us the points through which the curve must pass, which would be a water line. But, as this is performed exactly in the same manner as the water line that represents the third transom, we judge it unnecessary to form it in the plate.

The rails of the head are projected on the sheer plane, according to their true hangings: and, in order to find their true lengths, draw the dotted line S T, parallel to the keel at the height of the rails, upon the head. We must then determine the station of the cat-head upon the floor plane; and likewise the thickness of the head at the rail; and let fall a perpendicular from the point T, where the line S T intersects the cat-head in the sheer plane, to the point T in the floor plane; and likewise a perpendicular from S in the sheer, to S in the floor plane; and draw the line T S: S S, in the floor plane, being half the thickness of the head of the figure at the rail; so shall T S, in the floor plane, be the true length of the rail. Let the line T S, in the sheer plane, be divided into any number of equal parts: suppose into the points x, y, z; from which points draw perpendiculars to the line T S, to be limited by the rail. Divide the line T S, in the floor plane, into the same number of equal parts, in the points x, y, z. Draw perpendiculars to these points, and make them equal to the corresponding ones in the sheer plane; so we shall have the points through which the curve of the rail must pass.

We have now shewn different ways of forming all the timbers; where it must be observed, that we have always supposed every timber to be one intire piece of wood from the keel to the top of the side; whereas, in reality, they are in several different pieces; the head of the lower piece being cut square to join to the heel of the next above it: and, in order to support these joinings, another set of pieces are cut, and joined together in such a manner, that, if both the sets were fastened together, the joinings in one set would be nearly against the middle of the pieces in the other set. In this manner are all the frames fastened and erected, as if each was one piece of wood.

The pieces laid across the keel, to which they are fastened, are called floor timbers: the other pieces are called futtocks, except that which goes to the top of the side, which is called a top timber. Hence it is plain that the mould which serves for the floor timber, will serve for the lower part of the corresponding futtock. The mould for the upper part of the first futtock will be the same with that for the lower part of the second; and the mould for the lower part of the top timber will be the same with that of the upper part of the corresponding futtock. It is also of great importance, in building, to give proper scarps to the timbers. *Murray on Ship-building.*

SHIPWRIGHT'S *Sector*, the name of an instrument, invented by Mr. Mungo Murray, for forming the plane of a ship called the body.

This sector has seven lines on each leg, meeting at the center of the joint, numbered I, II, III, IV, &c. so that every line upon one leg has a corresponding one upon the other, both divided and numbered alike. The after body is upon one side, and the fore body on the other.

The lines for the after body are as follows. See plate CXVIII. *fig. 1.*

I. Has five divisions, viz. $\oplus$, 4, 1st dl, 8, ftⁿ; and marked at the end H B T^r, denoting the height of the top timber breadth line at four timbers; ftⁿ is the stern timber, and 1st dl, the first diagonal in the body plane.

II. Has eight divisions, viz. $\frac{LC}{U, A, A, U}$, $\frac{U^r C^r}{S, 8, 4}$, $\oplus$, and marked at the end $\frac{1}{2}$ B T^r, denoting the half breadth of the top timber at three timbers. L^r C^r signifies the lower counter, and U^r C^r the upper counter; U

denotes the height, and A the rake of the counters, both taken from the wing transom; Sⁿ is the rake of the stern timber, which is likewise taken from the wing transom at the height of the sheer rail.

III. Has eight divisions, viz. dⁿ, u^r S. R i s, $\oplus$, 3, 5, 7, 8: it is marked at the end L H B, for the height of the lower breadth line for five timbers: dⁿ is for the distance between the frames, and R i s, for the distance between the lower breadth line, and the dead rising in the body plane: u^r S. is the radius of the upper breadth sweep.

IV. Is in two parts. The innermost has four divisions, viz. 7, 5, 3, $\oplus$, expressing the points where these timbers intersect the second diagonal in the body plane: it is marked at the end 2 R for the second ribband.

The outermost part has six divisions, viz. $\oplus$, 3, 5, 7, 8, W T, and marked at the end U H B for the height of the upper breadth line at five timbers, and at the wing transom denoted by W T.

V. Is likewise in two parts. The innermost has four divisions, viz. 7, 5, 3, $\oplus$, expressing the points where these timbers intersect the first diagonal: it is marked 1st R, for the first ribband.

The outermost part has eight divisions, viz. T, 8, 7, 5, 3, $\oplus$, k l, and then marked M $\frac{1}{2}$ Bⁿ, for the main half breadth of five timbers; T for that at the wing transom, and k l for the half breadth of the keel in midships; without which there is another division marked 3^d dl for the third diagonal.

VI. Has four divisions, viz. 7, 5, 3, $\oplus$, for the points where those timbers intersect the third diagonal: it is marked 3d R, denoting the third ribband; without which there is another division marked 2d dl, for the second diagonal.

VII. Has five divisions, viz. 7, $\frac{1}{2}$ B F l, 5, 3, $\oplus$. $\frac{1}{2}$ B F l, denotes the half breadth of the floor: the other four are for the points where those timbers intersect the fourth diagonal: it is marked 4th R, denoting the fourth ribband; without which there is another division for the rake of the post marked R^k P.

The height of the gun-deck is between N^o. IV. and V. G D $\oplus$ for that in midships, and G D a for that at the post. There is likewise another division between N^o. I. and II. for the fourth diagonal: it is marked $\frac{1}{2}$ 4th dl, which must be doubled, because the length of the sector will not contain the whole.

The Lines for the Fore Body are.

I. Has three divisions, viz. H^r stem, $\frac{G^d, H^d}{\text{rake } f^r G}$ denoting the height of the stem; and its rake from timber G at the gun-deck and head.

II. Has four divisions, viz. d, b, and these marked H^r T^r, for the height of the top timber line at these timbers; and again d, b, for the $\frac{1}{2}$ breadth of those timbers; and the line marked $\frac{1}{2}$ B T R.

III. Has four divisions, viz. d^r F for the distance between the frames, and c, e, g; it is marked L H B, denoting

noting the height of the lower breadth line at these timbers.

IV. Is in two parts. The innermost has four divisions, viz. *g, e, c, ⊕*, for the points of intersection of these timbers with the second diagonal: it is marked 2^d R for the second ribband.

The outermost part has three divisions, viz. *c, e, g*: it is marked U H B, denoting the height of the upper breadth line at these timbers.

V. Is in two parts. The innermost has four divisions, viz. *g, e, c, ⊕*, for the points of intersection of these timbers with the first diagonal: it is marked 1st R for the first ribband.

The outermost part has four divisions, viz. *g, e, c, ⊕*: it is marked M $\frac{1}{2}$ Bth, for the main half breadth at these timbers.

VI. Has four divisions, viz. *g, e, c, ⊕*, for the points of intersection of these timbers with the third diagonal: it is marked 3^d R, for the third ribband.

VII. Has four divisions, viz. *g, e, c, ⊕*, for the points of intersection of these timbers with the fourth diagonal: it is marked 4th R for the fourth ribband. The sweep of the stem is between N^o. III. and IV; and the height of the gun-deck between IV and V.

The use of this instrument we have already given under the preceding article. *Murray's Treatise on Ship-building.*

SHIRE, the same with county, a division, or portion of the kingdom.

SHIVERY *Salt*, a name given by the salt workers to a sort of salt very different from the common brine salt, and formed among the common sort in the boiling pan.

SHOAD, in mining, a train of metalline stones mixed with earth, lying sometimes near the surface, and sometimes at considerable depths; but always affords a sure indication to the miner, that the load or vein of ore is not far distant. The deeper the shoad lies, the nearer generally the vein is.

SHOAD-STONES, a name given by the Cornish miners to those loose masses of stone usually found about the entrance of mines; and sometimes running from the load or vein of ore to the surface of the earth.

SHOAL, in the sea language, denotes a place where the water is shallow.

SHOALED, among tin-miners, signifies fragments of ore, which by rains, currents of water, &c. are torn from the load or vein of ore.

SHOAR, or SHORE. See the article SHORE.

SHOE, *Calceus*, a covering for the foot, usually made of leather.

Horse-SHOES. See HORSE.

SHORE, or SHOAR, a place washed by the sea, or by some large river.

Count Marfigli divides the sea-shore into three portions; the first of which is that tract of land which the sea just reaches in storms and high tides, but which it never covers; the second part of the shore, is that which is covered in high tides and storms, but is dry at other times; and the third is the descent from this, which is always covered with water.

The first part is only a continuation of the continent, and suffers no alteration from the neighbourhood of the sea, except that it is rendered fit for the growth of some plants, and wholly unfit for that of others, by the saline steams and impregnations: and it is scarce to be con-

ceived by any, but those who have observed it, how far on land the effects of the sea reach, so as to make the earth proper for plants, which will not grow without this influence; there being several plants frequently found on high hills and dry places, at three, four, and more miles from the sea, which yet would not grow, unless in the neighbourhood of it, nor will ever be found elsewhere.

The second part or portion of the shore is much more affected by the sea than the former, being frequently washed and beaten by it. Its productions are rendered salt by the water, and is covered with sand, or with the fragments of shells in form of sand, and in some places with a tartarous matter deposited from the water; the colour of this whole extent of ground is usually dusky and dull, especially where there are rocks and stones, and these covered with a slimy matter.

The third part of the shore is more affected by the sea than either of the others, and is covered with an uniform crust of the true nature of the bottom of the sea, except that plants and animals have their residence in it; and the decayed parts of these alter it a little.

SHORT ACCENT, in grammar, a mark which shews, that the syllable over which it is placed is short. It is marked thus (˘).

SHORT-SIGHTEDNESS, *Myopia*, in surgery. See the article MYOPIA.

SHOT, in military affairs, includes all kinds of balls or bullets, for fire-arms.

Trundle SHOT, an iron-shot, about seventeen inches long, and sharp-pointed at both ends, with a ball of lead fastened upon it, about a hand-breadth from each end.

SHOULDER BONE, *humerus*, in surgery. See HUMERUS.

SHOULDER - BLADE, *scapula*. See the article SCAPULA.

SHOULDER - PITCH, among farriers, a disease in a horse, when the pitch or point of the shoulder is displaced.

SHOULDER - SPLAIT, a hurt which a horse receives from some dangerous slip, whereby the shoulder is parted from the breast.

SHOULDERING PIECE, among builders, the same with a bracket. See BRACKET.

SHOWER, a cloud resolved into rain, and discharged upon a certain tract of ground. See the article RAIN.

SHREW - MOUSE, or *Hardy SHREW*, in zoology, a genus of quadrupeds, of the order of the glires; the upper fore-teeth of which are ffid, and lower ones serrated: the upper canine teeth are very small, and four in number.

The shrew-mouse is an extremely singular little animal, which greatly resembles the common mouse, but is somewhat smaller.

SHRIMP, in ichthyology, the English name of two different species of the squilla, viz. the common shrimp, and the smooth nosed shrimp.

The common shrimp is the long-tailed squilla, with the snout serrated above and tridentated below; the body is oblong and rounded above the beak or snout; which distinguishes it from all the other species: it is long, of a lanceolated figure, sharp-pointed, and has eight denticulations above and three below. The smooth nosed shrimp, or long-tailed squilla, with a smooth snout, grows to the same size with the common shrimp; however, the body is thick, and the snout is very short, without the spines or denticulations of the other.

SHRINE, in ecclesiastical history, a case to hold the relics of some faint.

The word is formed from the Latin, *scrinium*, a desk or cabinet.

SHROVE - TUESDAY, in the Christian church, is the Tuesday after Quinquagesima Sunday. It is so called from the old Saxon word *shrive*, which signifies to confess: it having been a custom formerly in the Romish church, to confess their sins on that day, in order to receive the eucharist, and thereby qualify themselves for a more religious observation of Lent.

In process of time, this custom was changed into that of mutual invitations, in order to take leave of flesh-meat

and other dainties; and this made way for sports and other merriments, which at present make up the whole business of the carnival, or season immediately preceding Lent.

SHROWDING of *Trees*, the cutting or lopping off the top branches; it is only practised on those trees which are designed for fuel, or some present use, not being fit for timber.

SHRUB, *Frutex*, a woody plant, of a size less than a tree, and which, besides its principal stem and branches, frequently from the same root, puts forth several other considerable sets or stems.

SHUTTLE, in the manufactures, an instrument used by the weavers, which with the thread it contains, either of woolen, silk, flax, or other matters, serves to form the woofs of stuffs, cloths, linens, ribbands, &c. by throwing the shuttle alternately from right to left, and from left to right, across between the threads of the warp, which are stretched out lengthwise on the loom.

SI, in music, a seventh note lately added by Le Maire to the six ancient notes invented by Guido Aretin, by means of which the difficulty attending the ancient scale is avoided.

SIBERIA, or **ASIATIC RUSSIA**, the most northern country of Asia, situated between the sixtieth and one hundred and thirtieth degree east longitude, and between the forty-seventh and seventy-second degree north latitude; being upwards of two thousand miles in length from east to west, and one thousand five hundred miles in breadth from north to south. We include the Calmuc Tartars within the limits of Siberia, as they acknowledge themselves subject to the empire of Russia.

SIBYLS, *Sibyllæ*, in pagan antiquity, certain women, said to have been endued with a prophetic spirit, and to have delivered oracles fore-showing the fates and revolutions of kingdoms. We have in the writings of the ancients mention made of ten of them, the eldest of whom being named Sibylla, all the rest of the same sex, who afterwards pretended to the like fatidical spirit, were called from her Sibyls. The most eminent of the ten, mentioned in history, was she, whom the Romans called Sibylla Cumæa or Erythræa. She was born at Erythræ in Ionia, from whence she removed to Cumæ in Italy, and there delivered all her oracles from a cave or subterraneous vault dug out of the main rock.

Justin Martyr, who had been upon the place, speaking of it, and the Sibyl, tells us, it was reported, that this Sibyl was a Babylonian by descent, and the daughter of Berofus, who wrote the Chaldaic history: but how she came into Italy, no one could tell. As to the cave, where she delivered her oracles, he tells us, it was a kind of chapel, or oratory, hewn out of the main rock. Here he was shewn three hollow places, in which she used to wash herself, and a high advanced seat, from which, they pretended, she delivered her oracles. This place continued to be seen many hundred years after, till the year 1539, when a violent earthquake utterly destroyed this chapel of the Cumæan Sibyl. But travellers are still shewn a vault, which they call the Grotto of the Sibyl to this day.

The Sibylline oracles, of which we hear so much in the Roman history, had their origin as follows. In the reign of Tarquin the second, a certain woman came to Rome, and brought with her nine books of oracles, which she offered to the king, demanding for them three hundred pieces of gold. Tarquin refusing to give her that price for them, she burnt three of the nine, and then offered him the remaining six at the same price. Being again rejected by the king, who thought her mad, she burnt three more of them, and then offering him the remaining three, persisted in demanding the same price for these, as she did at first for all the nine. At which strange procedure Tarquin being moved, consulted the augurs thereupon, who earnestly advised him to purchase the books. Hereupon the money being paid, and the books delivered to the king, the woman gave him strict charge to keep them safely, as containing oracles relating to the future state of Rome: after which she disappeared, and was never more seen. Tarquin, putting these books into a stone coffin, laid them up in a vault

under the Temple of Jupiter Capitolinus, and appointed two of the principal nobility to keep them, with strict orders to let no one peruse them.

After the dissolution of the regal power, the commonwealth made these books a main engine of state, for quieting the people in all disturbances. For, whenever any great misfortune befel them, or any prodigies affrighted them, these books were ordered to be consulted, and the keepers of them always reported such answers as served the purposes of the government. These guardians of the Sibylline books were at first but two, and were then called Duumviri: afterwards they were increased to ten, and were then called Decemviri: lastly, their number was augmented to fifteen, and then they had the name of Quindecemviri. They were always chosen out of the Patrician families, and held the office for life, being exempted from all burthens of the state both civil and military.

These books were carefully kept, till the civil wars of Sylla and Marius; when the Capitol being accidentally set on fire, and burnt down to the ground, the Sibylline oracles were burnt with it. This was eighty-three years before Christ. Seven years after, the Capitol being rebuilt, the senate resolved, if possible, to restore these oracles. Accordingly they sent ambassadors to Erythræ in Ionia, where the Cumæan Sibyl was born, and where many of that Sibyl's oracles were said to be preserved, to take copies of as many as they could find. These deputies, having collected together, from the papers of several private persons, about a thousand verses in the Greek language, pretended to be the prophecies of this and other Sibyls, brought them to Rome; and at the same time enquiry being also made at Samos, Ilium, and other cities in Greece, Sicily, Africa, and Italy, for the like oracles and prophecies of the Sibyls, great numbers that pretended to be such were gathered together, and laid up in the Capitol, to supply the place of those that were burnt. But the use which the Romans proposed to make of these oracles, being much defeated by their being vulgarly known, and in the hands of many persons, a law was made that all who had any copies of them, should bring them in to the pretor of the city, and all were prohibited under pain of death to retain them. Notwithstanding this, many, that had transcripts of these oracles, still kept them privately in their hands, and their number increased daily. For this reason, Augustus, when he took upon him the high-priesthood, revived the abovementioned law: whereupon so many copies of these pretended prophecies being brought in, as amounted to a great multitude of volumes, he ordered them to be strictly examined, and having burnt and destroyed all that were disapproved, repositied the rest for the use of the state. These afterwards Tiberius caused to be re-examined, and burnt many more of them, preserving only such as were of moment, and useful to the state.

To these Sibylline oracles, as long as Rome continued heathen, great recourse was had; and they remained in use to the year of our Lord 399, when they were utterly destroyed. For, not long before that time, a prophecy being given out by the heathen Romans, pretended to be taken from the Sibylline writings, which imported that Peter having by magic founded the Christian religion to last for the term of 365 years only, it was at the end of this time wholly to vanish, and be no more professed in the world, and this term expiring in the year of our Lord 398; Honorius the Roman emperor, taking the advantage hereof to convict these writings of manifest forgery and imposture, ordered them all to be destroyed; and accordingly, the next year, Stilico, by virtue of the imperial decree, burnt the Sibylline books, and demolished the temple of Apollo, in which they were repositied.

It was out of the Sibylline books that Virgil took that famous prophecy, which makes the subject of his fourth Eclogue. This prophecy the poet, with fine address, applies to the birth of the son of Pollio: but the ancient Christian writers generally understood it to be a direct prediction of the coming of the Messiah. And it was from the same source, that Suetonius derived what he says, "That in the time of Vespasian a constant and general

neral opinion prevailed throughout the whole East, that fate had decreed, that about that time should come forth out of Judea those who should obtain the empire of the world." Which prediction is likewise ascribed by the Christian writers to the birth of Christ, and the propagation of his religion over the whole world. Thus the Sibyls are supposed to have foretold the Messiah, and the establishment of the Christian religion.

Josephus the historian quotes, in his history, a passage from the Sibyls, which mentions the deluge. Clemens Alexandrinus assures us, that St. Paul in his preaching, often quoted the Sibylline books, and referred the Gentiles to them. And the ancient fathers of the church, as Justin Martyr, Athenagoras, Theophilus of Antioch, Tertullian, Lactantius, Eusebius, St. Jerom, St. Austin, and others, made good use of them against the pagans; which occasioned these writers to be distinguished by the name of Sibyllists.

There is still preserved, in eight books of Greek verses, a collection of oracles pretended to be the Sibylline. This collection must have been made after the year 138, because mention is made in it of the emperor Antoninus Pius; and before 167, because Justin Martyr several times quotes it. But whether this was a true collection of the Sibylline oracles, or a forgery occasioned by the pious fraud of some over-zealous Christian of those times, is a question among learned men. The generality of the critics look upon it as spurious, because it contains such an abstract of the doctrines of the Old and New Testament, as none but a Christian could write. Besides which, it carries several other marks of imposture; such as the notion of the Millenarians, which was not broached till the second century; and a succession of all the Roman emperors from Julius Cæsar to Antoninus Pius, in such a manner as shews it to have been written rather as a history of things past, than as a prophecy of future events. The learned author of the Connection of the Old and New Testament has sifted this matter to the bottom, and given his opinion concerning the Sibyls and their books at large. The substance of what he says upon this subject is as follows.

1. Who, or how many the Sibyls were, or when, or where they lived, various authors, as to these particulars, write variously of them; and the most that they say concerning them is manifestly fable and fiction.

2. How muchsoever they might pretend to prophecy, they could not have it by divine inspiration. For most of the oracles, that were produced from them, when consulted by the Romans, directed to the most idolatrous and abominable rites, such as human sacrifices.

3. Therefore, if they had the gift of prophecy, they must have received it from diabolical or evil spirits. Or, the world being too fond of prophecies, they might take advantage of this weakness, to impose false pretences under this name. That some of them were found to be such by the heathens themselves, appears from hence, that Augustus burnt two thousand volumes of these pretended oracles, and Tiberius many more of them.

4. The story of the three books of the Sibyls sold to Tarquin was, most probably, a state-trick, or fetch of politics:

5. None being allowed to inspect the Sibylline oracles, excepting only the sacred college, the members of which were enabled thereby to counterfeit such answers as best suited the exigencies of the government. Thus, when the Romans found it inconvenient for the state, to restore Ptolemy Auletes to his kingdom, though they had engaged to do it, an oracle was produced out of the Sibylline books to forbid the thing.

6. The burning of the first Sibylline books, and the earnest desire of the senate to restore them, was a fruitful source of forgeries of this sort.

7. The prophecies, which so plainly point out the coming of the Messiah, might come originally from the Jews themselves. For it is well known, that the Jews, at the time of the destruction of Jerusalem by the Romans, expected a temporal Messiah or deliverer. After the ruin of their city, being dispersed among the heathens, and talking much about those prophecies, which seemed to promise them such a prince, these predictions

might grow into reputation among the heathens, and be insensibly ingrafted among the oracles of the Sibyls, as if they had come from them. And God might permit this, that the coming of his Son might be foretold to the heathens.

8. A collection being made of the Sibylline oracles, and by some Grecian digested into Greek verses, about the time of our Saviour, and the abovementioned prophecies having been found therein, this operated much to the advantage of Christianity in the earliest times. And this is the reason why the Christian writers, in their disputes with the Pagans, so often appeal to the Sibylline oracles.

SICYANIA, or **GOURD-WORM**, in natural history, a genus of insects, being of an oblong form, flat on the belly, and rounded on the back; the skin is soft; and the mouth large, horizontal, and emarginated, or dented in the middle. It grows to two thirds of an inch in length, though more usually it is not half that size; its breadth is nearly two thirds of its length.

SIDE, *Latus*, the half of any thing, as an animal, a ship, &c. The sides of an animal are distinguished into the right and left side; but those of a ship, into the star-board and larboard side.

In geometry, the sides of a rectilinear figure are the lines which form its periphery.

SIDE of a Power, the same with its root. See the article **ROOT**.

SIDE-LAYS, among hunters, dogs that are let slip at deer, as he passes.

SIDES-MEN, or **SYNOD'S MEN**, persons who, in large parishes, are appointed to assist the church-wardens in their enquiry and presentments of such offenders to the ordinary, as are punishable in the spiritual court.

SIDERATION, a term used for a sphacelus or mortification.

Some also use the term sideration for the blasting or blighting of trees, plants, &c.

SIDEREAL YEAR. See **YEAR**.

SIDERITES, in natural history, the same with the magnet. See **MAGNET**.

SIDERITIS, Iron-wort, in botany, a genus of plants, with a monopetalous, labiated, and ringent flower; the seeds are four in number, and contained in the cup, which serves instead of a capsule; add to this, that the flowers grow in circles round the stalks, at the joinings of the leaves.

SIEGE, in the art of war, the encampment of an army round a place, in order to take it, either by formal attacks, or famine.

The word is French, and literally signifies a seat.

The method of encamping is very different in a siege, from that observed on a march; as in the former the army environs the place without cannon-shot, that nothing may enter. If the place be situated on a river, a detachment is sent to the other side, and bridges of communication made both above and below the town. The army also encamp with their backs to the town, with the battalions and squadrons interlined; and, having taken possession of all the heights, whence the enemy may be annoyed, the engineers trace the lines of circumvallation and contravallation, every regiment working at the place appointed them.

When the general has disposed his guards, as well towards the place as towards the country, and established the lieutenant-generals to command in the particular quarters, he goes with the engineers to view the place, and orders the attack in the place judged the weakest.

To form a siege, there must be an army sufficient to furnish five or six reliefs for the trenches, pioneers, guards, &c. also artillery, and magazines furnished with a sufficient quantity of ammunition and provisions; and an hospital, for taking care of the wounded.

To raise a siege, is to give over attacking a place; ordering the works and posts before it to be levelled.

SIEUR, a title of respect among the French, like *master* among us: it is much used by the lawyers, as also by superiors in their letters to inferiors.

SIGATI-GUSH, in zoology, the name of a Persian animal, of the lynx kind, and no way differing from the lynx itself, but in that it has no spots. Its ears have the

fine velvety black pencil of hairs at their top, which are the distinguishing character of the lynx; and these creatures differ so much in the variations and different dispositions of their spots, that probably this is no other than an accidental variety of the same species.

SIGHT, or **VISION**, in optics. See **EYE** and **VISION**.

SIGHTS, in mathematics, imply two thin pieces of brass, &c. placed perpendicularly on the two extremities of the index of a theodolite, circumferentor, &c. each of which has an aperture or slit in the middle, through which the visual rays pass to the eye, and distant objects are seen.

SIGILLATA TERRA, a name given to several earths or boles, to signify their being genuine; the principal is that dug in the island Lemnos.

SIGMOIDES, a word used by medicinal writers to express any thing that is in the shape of the letter sigma. The valves of the heart have this epithet applied to them: the coracoid process of the scapula is also expressed by the same word; the semicircular cavity of the cubit, at the articulation of the fore-arm with the humerus, is sometimes also called the sigmoidal cavity; and the cartilages of the sigmoidal circles of the aspera arteria, or wind-pipe, have their denomination from the same occasions.

SIGN, a sensible mark or character, denoting something absent or invisible.

SIGN, in algebra. See **CHARACTER**.

SIGN, in medicine, implies some appearance in the body, distinguishable by the senses, whence, by just reasoning, is inferred the presence, nature, state, event of health, a disease, or death.

Those which indicate the present condition of a body, whether sick or well, dying or the like, are called diagnostic signs. Those which foretell the future state thereof, are called prognostic signs. And that sign which is peculiar to the disease, and inseparable from it, as arising from the nature thereof, is called a pathognomonic sign.

SIGN, in astronomy, the twelfth part of the ecliptic, or a portion containing thirty degrees thereof.

The ancients divided the ecliptic into twelve segments, called signs, which they denominated from the constellations, which, at the time the names were imposed, were situated near those portions of the ecliptic. But the constellations, by the precession of the equinox, have changed their places, the constellation Aries being got into the sign Taurus, and the constellation Taurus into the sign Gemini, &c. The names and order of the twelve signs are as follow:

Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius and Pisces, the first six of which are called northern signs, and the latter southern signs.

SIGN-MANUEL, in law, is used to signify any bill, or writing, signed by the king's own hand.

SIGNAL, a certain sign agreed upon for the conveying of intelligence, where the voice cannot reach.

Signals are given for the beginning of a battle, or an attack, usually with drums and trumpets; at sea they are given by firing guns, by lights, sails, flags, &c.

Signals have been in use in all ages. The ancients, who had no regular couriers or posts, made use thereof to convey intelligence of what passed at a great distance. For which purpose they placed centinels on the eminences, from space to space; some mention whereof we find made by Homer himself, *Iliad*. *Od.* v. 553, &c. *Odyss.* *Æ.* v. 261. Those people, thus disposed, lighted fires, or flambeaux, in the night-time. In the *Agamemnon* of *Æschylus*, that prince, at his departure for Troy, promises *Clytemnestra*, that, the very day the city should be taken, he would apprize her of his victory by fires lighted express. He keeps his word, and tidings are brought the princess, that Troy is taken, and that *Agamemnon's* signals are seen. *Frontinus* observes, they were in use among the Arabs; and *Bonaventura Vulcanius*, in his *Scholia* on *Aristotle's* book *De Mundo*, adds, that while the Moors were masters of the greatest part of Spain, they built, on the tops of the mountains, an infinity of turrets, or watch-houses,

called, in the Arabic, *atalayas*, a word the Spaniards still retain; whence, by fires, they could immediately alarm the whole kingdom. Indeed the custom was much more ancient than the Moors in Spain. *Q. Curtius* observes, it was very frequent among the Asiatics, in the time of *Alexander*. *Livy* and *Cæsar* both mention it as used among the Romans. *Polydore Virgil* shews it of great antiquity in England; and *Boethius* adds, that, in several places in England, there are the remains of huge poles that have served for this purpose.

SIGNALS at Sea, are signs made by the admiral or commander in chief of a squadron of ships, either in the day or by night, whether for sailing, for fighting, or for the better security of the merchant ships under their convoy.

These signals are very numerous and important; being all appointed and determined by order of the lord high-admiral, or lords of the admiralty; and communicated in the instructions sent to the commander of every ship of the fleet or squadron before their putting out to sea.

SIGNALS by Day. When the commander in chief would have them prepare for sailing, he first looses his fore-top-sail, and then the whole fleet are to do the same. When he would have them unmoor, he looses his main-top-sail, and fires a gun, which in the royal navy is to be answered by every flag-ship. When he would have them weigh, he looses his fore-top-sail, and fires a gun, and sometimes haws home his sheets: the gun is to be answered by every flag-ship, and every ship to get to sail as soon as it can. If with the leeward-side, the sternmost ship is to weigh first. When he would have the weather-most and head-most ships to tack first, he hoists the union-flag at the fore-top-mast-head, and fires a gun, which each flag-ship answers; but, if he would have the stern-most and leeward-most ships to tack first, he hoists the union-flag at the mizen-top-mast-head, and fires a gun; and, when he would have all the whole fleet tack, he hoists an union, both on the fore and mizen-top-mast-heads, and fires a gun. When, in bad weather, he would have them wear, and bring to the other tack, he hoists a pendant on the ensign-staff, and fires a gun; and then the leeward-most and sternmost ships are to wear first, and bring on the other tack, and lie by, or go on with an easy sail, till he comes a-head: every flag is to answer with the same signal. If they are lying by, or sailing by a wind, and the admiral would have them bear up and sail before the wind, he hoists his ensign and fires a gun, which the flags are to answer: and then the leeward-most ships are to bear up first, and to give room for the weather-most to wear, and sail before the wind with an easy sail, till the admiral comes a-head. But if it should happen, when the admiral hath occasion to wear and sail before the wind, that both jack and ensign be abroad, he will haul down the jack, before he fires the gun to wear, and keep it down till the fleet is before the wind. When they are sailing before the wind, and he would have them bring to, with the star-board tacks aboard, he hoists a red flag at the flag-staff, on the mizen-top-mast-head, and fires a gun. But if they are to bring to with the lar-board tack, he hoists a blue flag at the same place, and fires a gun, and every ship to answer the gun. When any ship discovers land, he is to hoist his jack and ensign and keep it abroad, till the admiral or commander in chief answers him, by hoisting his; on sight of which, he is to haul down his ensign. If any discovers danger, he is to tack and bear up from it, and to hang his jack abroad from the main-top-mast cross-trees, and fire two guns: but, if he should strike or stick fast, then, besides the same signal with his jack, he is to keep firing, till he sees all the fleet observe him, and endeavour to avoid the danger. When any sees a ship or ships more than the fleet, he is to put abroad his ensign, and there keep it, till the admiral's is out, and then to lower it, as often as he sees ships, and stand in with them, that so the admiral may know which way they are, and how many; but if he be at such a distance, that the ensign cannot well be discovered, he is then to lay his head towards the ship or ships so descried, and to brail up his

low sails, and continue hoisting and lowering his top-sails, and making a waft with his top-gallant sails, till he is perceived by the admiral. When the admiral would have the vice-admiral, or he that commands in the second post of the fleet, to send out ships to chace, he hoists a flag, striped white and red, on the flag-staff, at the fore-top-mast head, and fires a gun. But, if he would have the rear-admiral do so, he then hoists the same signal on the flag-staff, at the mizen-top-mast-head, and fires a gun. When the admiral would have any ship to chace to windward, he makes a signal for speaking with the captain, and he hoists a red flag in the mizen-throwds, and fires a gun: but, if to chace to leeward, a blue flag; and the same signal is made by the flag in whose division that ship is. When he would have them give over chace, he hoists a white flag on his flag-staff at the fore-top-mast-head, and fires a gun: which signal is to be made also by that flag-ship which is nearest the ship that gives chace, till the chasing ship sees the signal. In case of springing a leak, or any other disaster that disables their ship from keeping company, they are to hawl up their courses, and fire two guns. When any ship would speak with the admiral, he must spread an English ensign, from the head of his main, or fore-top-mast, downwards on the throwds, lowering his main, or fore-top-sail, and firing guns, till the admiral observe him; and if any ship perceive this, and judgeth the admiral doth not, that ship must make the same signal, and make the best of his way to acquaint the admiral therewith, who will answer by firing one gun. When the admiral would have the fleet to prepare to anchor, he hoists an ensign, striped red, blue, and white, on the ensign-staff, and fires a gun, and every flag-ship makes the same signal. If he would have the fleet moor, he hoists his mizen-top-sail, with the clew-lines hawled up, and fires a gun. If he would have the fleet cut or slip, he looses both his top-sails, and fires two guns; and then the leeward ships are to cut or slip first, to give room to the weathermost to come to sail. So if he would have any particular ship to cut or slip, and to chace to windward, he makes the signal for speaking with that ship, hoists a red flag in the mizen throwds, and fires a gun: but, if the ship is to chace to leeward, he hoists a blue flag as before. If he would have the fleet exercise their small arms, he hoists a red flag on the ensign-staff, and fires a gun; but, if the great guns, then he puts up a pendant over the red flag.

SIGNALS by Night. — To be observed at an anchor, weighing anchor, and sailing, are as follow. When the admiral would have the fleet to unmoor, and ride short, he hangs out three lights, one over another in the main-top-mast throwds, over the constant light in the main-top, and fires two guns, which are to be answered by flag-ships: and each private ship hangs out a light in the mizen throwds. Note, That all guns, fired for signals in the night, must be fired on the same side, that they may make no alteration in the sound. When he would have them weigh, he hangs a light in the main-top-mast throwds, and fires a gun, which is to be answered by all the flags, and every private ship must hang out a light in his mizen-throwd. When he would have them tack, he hoists two flags on the ensign-staff, one over another, above the constant light in his poop, and fires a gun, which is to be answered by all the flags; and every private ship is to hang out a light extraordinary, which is not to be taken in, till the admiral takes in his. After the signal is made, the leeward-most and stern-most ships must tack as fast as they can, and the stern-most flag-ship, after he is about on the other tack, is to lead the fleet, and him they are to follow, to avoid running foul of one another in the dark. When he is upon a wind, and would have the fleet veer, and bring to on the other tack, he hoists up one light at the mizen-peek, and fires three guns, which is to be answered by the flag-ships, and every private ship must answer, with one light at the mizen-peek. The stern-most and leeward-most ships are to bear up as soon as the signal is made. When he would have them, in blowing weather, to lie a try, short, or a hull, or with the head-sails braced to the mast, he will form lights of equal height, and fire

five guns, which are to be answered by the flag-ships; and then every private ship must shew four lights: and after this, if he would have them to make sail, he then fires ten guns, which are to be answered by all the flags, and then the head-most and weather-most ships are to make sail first. When the fleet is sailing large, or before the wind, and the admiral would have them bring to, and lie by with their star-board tacks aboard, he puts out four lights in the fore-throwds, and fires six guns; but if with the larboard tacks aboard, he fires eight guns, which are to be answered by the flag-ships; and every private ship must shew four lights. The wind-most ships must bring to first. Whenever the admiral alters his course, he fires one gun, without altering his lights, which is to be answered by all the flag-ships. If any ship hath occasion to lie short, or by, after the fleet hath made sail, he is to fire one gun, and shew three lights in his mizen-throwds. When any one first discovers land, or danger, he is to shew as many signs as he can, to fire one gun, and to tack, or bear away, from it: and if any one happen to spring a leak, or any be disabled from keeping company with the fleet, he hangs out two lights of equal height, and fires guns till he is relieved by some ship of the fleet. If any one discovers a fleet, he is to fire guns, make false fires, put one light out on the main-top, three on the poop, to steer after them, and to continue firing of guns, unless the admiral call him off, by steering another course, and fire two or three guns; for then he must follow the admiral. When the admiral anchors, he fires two guns, a small space of time one from the other, which are to be answered by the flag-ships; and every private ship must shew two lights. When the admiral would have the fleet to moor, he puts a light on each top-mast-head, and fires a gun, which is to be answered by the flag-ships, and every private ship is to shew one light. If he would have them lower their yards and top-masts, he hoists one light upon his ensign-staff, and fires one gun; which is to be answered by the flag-ships, and every private ship must shew one light. And when he would have them hoist their yards and top-masts, he puts out two lights, one under the other, in the mizen-top-mast throwds, and fires one gun; which is to be answered by the flag-ships, and each private ship must shew one light in the mizen-throwds. If any strange ship be discovered coming into the fleet, the next ship is to endeavour to speak with her, and bring her to an anchor, and not suffer her to pass through the fleet. And if any one discovers a fleet, and it blow so hard that he cannot come to give the admiral notice timely, he is to hang out a great number of lights, and to continue firing gun after gun, till the admiral answers him with one. When the admiral would have the fleet to cut or slip, he hangs out four lights, one at each main-yard-arm, and at each fore-yard-arm, and fires two guns, which are to be answered by the flag-ships, and every private ship is to shew one light.

SIGNALS used, when a Fleet sails in a fog. — If the admiral would have them weigh, he fires ten guns; which every flag-ship is to answer. To make them tack, he fires four guns, which are to be answered by the flag-ships; and then the leeward-most and stern-most ships must tack first, and, after they are about, to go with the same sail they tacked with, and not to lie by, expecting the admiral to come a-head: and this is to avoid the danger of running foul of one another in thick weather.

When the admiral brings to, and lies with his head-sails to the mast: if with the star-board tack aboard, he fires six guns; but, if with the lar-board tack, he fires eight guns, which the flag-ships are to answer. And after this, if he makes sail, he fires ten guns, which the flag-ships must answer, and then the head-most and weather-most ships are to make sail first. If it grow thick and foggy weather, the admiral will continue sailing, with the same sail set that he had before it grew foggy, and will fire a gun every hour, which the flag-ships must answer, and the private ships must answer, by firing of muskets, beating of drums, and ringing of bells. But if he be forced to make either more or less sail than he had, when the fog began, he will fire a gun every

every half-hour, that the fleet may discern, whether they come up with the admiral, or fall a-stern of him; and the flags and private ships are to answer as before. If any one discovers danger; which he can avoid, by tacking and standing from it, he is to make the signal for tacking in a fog; but if he should chance to strike and stick fast, he is to fire gun after gun, till he thinks the rest have avoided the danger. When the admiral would have the fleet to anchor, he fires two guns, which the flags are to answer; and after he hath been half an hour at an anchor, he will fire two guns more, to be answered by the flags, as before; that all the fleet may know it.

SIGNALS for calling Officers on board the Admiral.—When the admiral puts abroad an union-flag in the mizen-shrowds, and fires a gun, all the captains are to come aboard him: and if, with the same signal, there be also a waft made with the ensign, then the lieutenant of each ship is to come on board. If an ensign be put abroad in the same place, all the masters of the ships of war are to come on board the admiral. If a standard on the flag-staff be hoisted at the mizen-top-mast-head, and a gun fired, then all the flag-officers are to come aboard the admiral. If the English flags only, then a standard in the mizen-shrowds, and fire a gun: if the flags and land general officers, then the admiral puts abroad a standard at mizen-top-mast-head, and a pendant at mizen-peek, and fires a gun. If a red flag be hoisted in the mizen-shrowds, and a gun fired; then the captains of his own squadron are to come aboard the admiral; and if, with the same signal, there be also a waft with the ensign, the lieutenant of each ship must come aboard. If he hoists a white-flag, as before, then the vice-admiral, or he that commands in the second post, and all the captains of his squadron, are to go on board the admiral: if a blue flag, &c. then the rear-admiral, and the captains of his squadron, must come on board; and if a waft, as before, the lieutenants. When a standard is hoisted on the ensign-staff, and gun fired, the vice and rear-admirals must come on board the admiral's ship. When the admiral would speak with the captains of his own division, he will hoist a pendant on the mizen-peek, and fire a gun: and if with the lieutenants, a waft is made with the ensign, and the same signal: for whenever he would speak with the lieutenants of any particular ship, he makes the signal for the captain, and a waft also with the ensign. When the admiral would have all the tenders in the fleet come under his stern, and speak with him; he hoists a flag, yellow and white, at the mizen-peek, and fires a gun. But if he would speak with any particular ship's tender, he makes a signal for speaking with the captain she tends upon, and a waft with the jack. If all the pinaces and barges are to come on board, manned and armed, the signal is a pendant on the flag-staff, hoisted on the fore-top-mast-head, and a gun fired; and if he would have them chase any ship, vessel, or boat, in view, he hoists the pendant, and fires two guns. The signal for the long boats to come on board him, manned and armed, is the pendant hoisted on the flag-staff and the mizen-top-mast-head, and a gun fired; and if he would have them chase any ship, vessel, or boat, in open view, without coming on board him, he hoists the pendant, as aforesaid, and fires two guns. When the admiral would have all the boats in the fleet come on board him, manned and armed, he hoists a pendant on the flag-staff, both on the fore-top-mast, and mizen-top-mast-head, and fires one gun: but if he would have them chase he hoists his pendants, as before, and fires two guns. When the admiral would speak with the victualler, or his agent, he puts an English ensign in the mizen-top-mast-shrowds; and when with him that hath the charge of the gunner's stores, he will spread an ensign at his main-top-sail-yard-arm.

SIGNALS for managing a Sea-Fight. When the admiral would have the fleet form a line of battle, one ship a-head of another, he hoists an union-flag at the mizen-peek, and fires a gun; and every flag-ship does the like. But when they are to form a line of battle, one a-breast of another, he hoists a pendant with the union-flag, &c. When he would have the admiral of the white, or he that commands in the second post, to tack, and endeavour to gain the wind of the enemy, he

spreads a white flag under the flag at the main-top-mast-head, and fires a gun; and when he would have the vice admiral of the blue do so, he doth the same with the blue flag. If he would have the vice-admiral of the red do so, he spreads a red flag from the cap, on the fore-top-mast-head, downward on the back-stay; if the vice-admiral of the blue, he spreads a blue flag, &c. and fires a gun. If he would have the rear-admiral of the red do so, he hoists a red flag at the flag-staff, at the mizen-top-mast-head: if the rear-admiral of the white, a white flag; if the rear-admiral of the blue, a blue flag, and under it a pendant of the same colour, with a gun. If he be to leeward of the fleet, or any part of it; and he would have them bear down into his wake or track, he hoists a blue flag at the mizen-peek, and fires a gun. If he would be to leeward of the enemy and his fleet, or any part of it to be to leeward of him; in order to bring these ships into the line, he bears down with a blue flag at the mizen-peek, under the union-flag, which is the signal for battle, and fires a gun: and then those ships, that are to leeward of him, must endeavour to get into his wake or track, according to their station in the line of battle. When the fleet is sailing before the wind, and he would have him, who commands in the second post, and the ship of the star-board quarter to clap by the wind, and come to the starboard tack, he hoists a red flag at the mizen-top-mast-head; but a blue one, if he would have ships of the larboard quarter come to the lar-board tack, with a gun. If the van are to tack first, he spreads the union-flag at the flag-staff, on the fore-top-mast-head, and fires a gun, if the red flag be not abroad; but if it be, then he lowers the fore-top-sails a little; and the union flag is spread from the cap of the fore-top-mast downwards; and every flag-ship doth the same. If the rear be to tack first, he hoists the union-flag on the flag-staff, at the mizen-top-mast-head, and fires a gun; which all the flag-ships are to answer. If all the flag-ships are to come into his wake or track, he hoists a red flag at his mizen-peek, and fires a gun; and all the flag-ships must do the same. If he would have him that commands in the second post of his squadron to make more sail, though he himself shorten sail, he hoists a white flag on the ensign-staff. But, if he that commands in the third post be to do so, he hoists a blue flag, and fires a gun, and all the flag-ships must have the same signal. Whenever he hoists a red flag on the flag-staff at the fore-top-mast-head, and fires a gun; every ship in the fleet must use their utmost endeavour to engage the enemy, in the order prescribed them. When he hoists a white flag at his mizen-peek, and fires a gun; then all the small frigates of his squadron, that are not of the line of battle, are to come under the stern. If the fleet be sailing by a wind in the line of battle, and the admiral would have them brace their head sails to the mast, he hoists up a yellow flag, on the flag-staff, at the mizen-top-mast-head, and fires a gun; which the flag-ships are to answer: and then the ships in the rear must brace first. After this, if he would have them fall their head-sails, and stand on, he hoists a yellow flag on the flag-staff of the fore-top-mast-head, and fires a gun, which the flag-ships must answer, and then the ships in the van must fall first, and stand on. If, when this signal is made, the red flag at the fore-top-mast-head be abroad, he spreads the yellow flag under the red. If the fleets being near one another, the admiral would have all the ships to tack together, the sooner to lie in a posture to engage the enemy; he hoists an union-flag on the flag-staves at the fore and mizen-top-mast-heads, and fires a gun; and all the flag-ships are to do the same. The fleet being in a line of battle, if he would have the ship that leads the van, hoist, lower, set, or haul, up any of the sails, he spreads a yellow flag, under that at his main-top-mast-head, and fires a gun, which signal the flag-ships are to answer; and then the admiral will hoist, lower, set, or haul up the sail, which he would have the ship that leads the van do; which is to be answered by the flag-ships of the fleet. When the enemy runs, and he would have the whole fleet follow them, he makes all the sail he can after them himself, takes down the signal for the line of battle, and fires two guns out of his forechase, which the flag-ships answer; and then every ship is to endeavour to come up with, and board the enemy.

enemy. When he would have the chace given over, he hoists a white flag at the fore-top mast-head, and fires a gun. If he would have the red squadron drawn into a line of battle, one a-breast of another, he puts abroad a flag, striped red and white, on the flag-staff at the main-top-mast-head, with a pendant under it, and fires a gun: if the white or second squadron is to do so, the flag is striped, red, white, and blue: if the blue or third squadron is to do so, the flag is a Genoese ensign and pendant; but if they are to draw into a line of battle, one a-head of another, the same signals are made without a pendant. If they are to draw into the line of battle one a-stern of another, with a large wind, and he would have the leaders go with the star-board tacks aboard by the wind; he hoists a red and white flag at the mizen-peek, and fires a gun: but if they should go with the lar-board tacks aboard by the wind, he hoists a Genoese flag at the same place; which signals, like others, must be answered by the flag-ships.

SIGNATURE, signing, a subscription, or the putting one's name at the bottom of an act or deed, in one's own hand-writing.

SIGNATURE of the Court of Rome, is a supplication answered by the pope, whereby he grants a favour, dispensation or collation to a benefice, by putting the fiat to it with his own hand; or the consensum is written in his presence. This signature at the bottom of the supplication, gives the name to the whole instrument.

SIGNATURE, in printing, is a letter put at the bottom of the first page, at least, in each sheet, as a direction to the binder, in folding, gathering, and collating them. The signatures consist of the capital letters of the alphabet, which change in every sheet: if there be more sheets than letters in the alphabet, to the capital letter is added a small one of the same sort, as A a B b; which are repeated as often as necessary. In large volumes it is usual to distinguish the number of alphabets, after the first three or four, by placing a figure before the signature, as 5B 6B, &c.

SIGNATURE is also used, by some naturalists, for the resemblance a vegetable or mineral bears to a part of the human body; which, by some fantastical people, is supposed to indicate its virtues and use.

SIGNET, one of the king's seals, used for sealing his private letters, and signing all grants which pass his majesty's hand by bill.

SIGNIFICATION, in general, denotes the meaning or import of a word, phrase, sign, device, emblem, or the like.

In law, it is used for the notifying an act, &c. to the opposite party, by a copy thereof given and attested by the proper officer.

SIGNIFICAVIT, in law, a writ which issues out of the court of chancery, on a certificate given by the ordinary of a person's standing excommunicated forty days, in order to have him imprisoned till he submits to the authority of the church.

SILENI, in antiquity, a sort of heathen demi-gods, the same with satyrs, which were called Sileni, when they came to be advanced in age.

SILIQUEA, in botany, the seed vessels, husk, pod, or shell of a plant of the leguminous kind.

SILIQUEOUS PLANTS, those which produce filiquæ, or seed pods.

SILK, *Sericum*, a very soft, fine, bright, delicate thread, the work of an insect called bombyx, or the silk-worm.

In the year 555, two monks brought from the East-Indies, to Constantinople, great quantities of silk-worms, with instructions for the hatching their eggs, rearing and feeding the worms, drawing out the silk, spinning and working it. Immediately manufactures were set up at Athens, Thebes, and Corinth. About 1130, Roger, King of Sicily, established a silk manufactory at Palermo, and another at Calabria, managed by workmen whom he brought from Athens, Corinth, &c. which that prince had conquered in his expedition to the Holy Land. By degrees the rest of Italy and Spain learned from the Sicilians and Calabrians, the management of the silk-worms, and the working of silk; and at length, a little before the reign of Francis I. began to imitate them.

The great advantage flowing from this new manufacture, made king James I. to be very desirous of its being introduced into England; accordingly it was recommended several times from the throne, and in the most earnest terms, to plant mulberry trees, &c. for the propagation of silk-worms, but unhappily without effect; though from the various experiments inserted in the Philosophical Transactions, and other places, it appears, that the silk-worm thrives, and works as well, in all respects, in England, as in any other part of Europe.

The silk-worm is an insect not more remarkable for the precious matter it furnishes for divers stuffs, than for the many forms it assumes, before and after its being enveloped in the rich cod or ball it weaves itself. From a small egg about the size of a pin's head, which is its first state, it becomes a pretty big worm, or maggot, of a whitish colour, inclining to yellow. In this state it feeds on mulberry-leaves, till, being come to maturity, it winds itself up into a silken bag, or case, about the size and shape of a pigeon's egg; and becomes metamorphosed into an aurelia: in this state it remains without any signs of life, or motion; till at length it awakes, to become a butterfly; after making itself a passage out of its silken sepulchre. And, at last, dying indeed, it prepares itself, by an egg, or seed it casts, for a new life; which the warmth of the summer weather assists it in resuming.

As soon as the silk-worm is arrived at the size and strength necessary for beginning his cod, he makes his web; for it is thus they call that slight tissue, which is the beginning and ground of this admirable work. This is his first day's employment. On the second, he forms his folliculus or ball, and covers himself almost over with silk. The third day he is quite hid, and the following days employs himself in thickening and strengthening his ball, always working from one single end, which he never breaks by his own fault, and which is so fine, and so long, that those who have examined it attentively, think they speak within compass, when they affirm, that each ball contains silk enough to reach the length of six miles.

In ten days time, the ball is in its perfection, and is now to be taken down from the branches of the mulberry-tree, where the worms have hung it. But this point requires a deal of attention, for there are some worms more lazy than others, and it is very dangerous waiting till they make themselves a passage, which usually happens about the fifteenth day of the month.

The first, finest, and strongest balls are kept for the grain, the rest are carefully wound; or if it is desired to keep them all, or if there be more than can be well wound at once, they lay them for some time in an oven moderately hot, or else expose them, for several days successively, to the greatest heats of the sun, in order to kill the insect, which, without this precaution, would not fail to open itself a way to go and use those new wings abroad, it has acquired within.

Ordinarily, they only wind the more perfect balls; those that are double, or too weak, or too coarse, are laid aside, not as altogether useless, but that, being improper for winding, they are reserved to be drawn out into skains. The balls are of different colours; the most common are yellow, orange-colour, isabella, and flesh-colour; there are some also of a sea-green, others of a sulphur-colour, and others white; but there is no necessity for separating the colours and shades to wind them apart, as all the colours are to be lost in the future scouring and preparing of the silk.

To wind SILK from off the Balls. Two machines are necessary, the one a furnace, with its copper; the other a reel, or frame, to draw the silk. The winder, then, seated near the furnace, throws into the copper of water over the furnace, first heated and boiled to a certain degree, which custom alone can teach, a handful or two of balls, which have been first well purged of all their loose furry substance. He then stirs the whole very briskly about with birchen rods, bound and cut like brushes; and, when the heat and agitation have detached the ends of the silks of the pods, which are apt to catch on the rods, he draws them forth, and joining ten or twelve,

or even fourteen of them together, he forms them into threads, according to the bigness required to the works they are destined for; eight ends sufficing for ribbands, and velvets, &c. requiring no less than fourteen. The ends, thus joined into two or three threads, are first passed into the holes of three iron rods, in the fore part of the reel, then upon the bobbins, or pullies, and at last are drawn out to the reel itself, and there fastened; each to an end of an arm or branch of the reel. Thus disposed, the workman, giving motion to the reel, by turning the handle, guides his threads, substitutes new ones, when any of them break, or any of the balls are wound out; strengthens them, where necessary, by adding others; and takes away the balls wound out, or that, having been pierced, are full of water.

In this manner, two workmen will spin and reel three pounds of silk in a day; which is done with greater dispatch than is made by the spinning-wheel or distaff. Indeed, all silks cannot be spun and reeled after this manner; either by reason the balls have been perforated by the silk-worms themselves, or because they are double, or too weak to bear the water; or because they are coarse, &c. Of all these together, they make a particular kind of silk, called *floretta*, which being carded, or even spun on the distaff, or the wheel, in the condition it comes from the ball, makes a tolerable silk.

As to the balls, after opening them with scissars, and taking out the insects, which are of some use for the feeding of poultry, they are steeped three or four days in troughs, the water whereof is changed every day to prevent their stinking. When they are well softened by this scouring, and cleared of that gummy matter the worm had lined the inside withal, and which renders it impenetrable to the water, and even to air itself, they boil them half an hour in a lye of ashes, very clear and well strained: and after washing them out in the river, and drying them in the sun, they card and spin them on the wheel, &c. and thus make another kind of *floretta*, somewhat inferior to the former.

As to the spinning and reeling of raw silks off the balls, such as they are brought from Italy and the Levant, the first is chiefly performed on the spinning-wheel; and the latter, either on hand-reels, or on reels mounted on machines, which serve to reel several skains at the same time.

As to the milling, they use a mill composed of several pieces, which may mill two or three hundred bobbins at once, and make them into as many skains.

The following is an account of a new improved *SILK Reel*, by the reverend Samuel Pullein, and it is hoped, will help to promote the culture of silk in our American colonies, and to bring it to that perfection which at present is scarce found in any country but Piedmont.

"When silk is reeled from the cocoons, the thread is smeared with the natural gum of the silk softened by the heat of the water out of which it is reeled. If the several rounds of this thread, as it falls on the reel, touch one another in their whole extent, it is then so glued together, as to be entirely useless for any perfection of manufacture, it being impossible to wind it off without tearing and breaking. This fault in the silk countries goes under the technical name of the *vitragé*; and there are many degrees of it, according to the cause by which it is produced.

"From the introduction of silk into Europe to this day, the preventing of the *vitragé* has employed some of the most knowing men in the countries where silk is produced.

"To change the position of the silk thread, that it might not always fall on the same part of the reel, the guide-stick was introduced. This received a progressive and regressive motion, by means of two wheels, the one fixed to the axle of the reel, and communicating its motion to the other by means of a band.

"To make these wheels perfect, certain determined and precise proportions are to be observed in the diameters of their grooves, otherwise, notwithstanding the motion of the guide-stick, there may be a total *vitragé* of the whole hank of silk; and, even when the proportion of the wheels is perfect, there may be reckoned up thirteen or fourteen accidents, any of which happening will cause a *vitragé*: but though these inconveniencies attend all

those reels which use a band, yet, because the ordinary sort of them are easily made, they are still used by the common people in most silk countries.

"No nation has brought its silk to a greater perfection than the Piedmontese: but it was only by slow degrees, and in a long tract of time, that they arrived at this. They first suppressed the old method of reeling the silk over a bobbin, which was found to give it a flat form; and they substituted in its stead that excellent method of the *croissure*, which renders it round and compact. They then applied themselves to correct the imperfections of the guide-stick, and to establish proper proportions between the wheels which gave it motion: but, notwithstanding these and other improvements, they still found, that, so long as these wheels were turned by means of a band, they could not arrive at the perfection necessary to make silk fit for organcine or warp, because the inaccurate motion of the band made the most just proportion which they could establish between the wheels quite ineffectual, and constantly produced a *vitragé*.

"It was on this account that they totally suppressed the usage of the band, and substituted in its place four wheels, with a determined number of teeth, whose revolutions, being uniform, gave the guide-stick a proper motion for preventing the *vitragé*. This, and some other regulations are established by laws, which are rigorously put in execution, lest the common people should, through indolence, relapse into their old customs. By adhering to this reel, the Piedmontese are able to give that perfection to their raw silk, which fits it to be thrown into organcine or warp; and to raise the value of each pound of silk reeled in this manner to one third more than it would have, if reeled otherwise.

"The French were desirous of making raw silk fit for organcine or warp among themselves, which hitherto they have had from Piedmont. Whether they thought the Piedmontese reel could not easily be brought into common use, or whether a little vanity hindered them from copying or improving the inventions of other nations, I will not determine. However that be, they applied themselves wholly to the improvement of the band-reel.

"Two persons, viz. M. St. Priest of Languedoc, and M. Vaucançon of the Academy of Sciences at Paris, have, within these nine or ten last years, brought the band-reel to the greatest perfection of which it is capable. Either of their reels will make raw silk fit for organcine or warp, provided they are accurately made; but a small error in their construction destroys their perfection. I have now in my possession a reel made according to M. Vaucançon's method; where I can shew, that in two wheels, whose diameters differ but very inconsiderably, one shall reel the silk properly, and the other throw it into a total *vitragé*. I have, however, given a description and plate of this reel, in a treatise on the culture of silk, which I published some time ago, because its contrivance is more simple than that of M. St. Priest, and performs as well.

"The Piedmontese reel is free from the inconveniencies of all those reels which use a band; the maker cannot easily err in the construction; the weather cannot affect its operation; nor is it subject, during its work, to the many irregularities of the band-reel. The chief objections which have hindered its being commonly used are, that four toothed wheels are more difficult to be made than two plain grooved ones; and that being made only of wood they are easily broken. So that it is necessary to have a double set of them, in order to prevent those delays which might happen by their breaking; because any delay in the reeling of silk occasions a considerable detriment.

"Our happier constitution doth not admit such rigorous laws as that of Piedmont. To make the common people adopt any new contrivance, they must not only know that it is the best, but they must also feel that it can be easily practised. Those who superintend public filatures in our colonies may indeed, for the present, keep their workmen to the Piedmontese reel; but public filatures can no more produce large quantities of silk than public spinning houses could produce the vast quantities of linen-yarn which are now raised from private family-wheels:

and when the management of silk-worms becomes more common in our colonies, and people find that, by reeling their own cocoons, their profit will be nearly doubled, and this with much less labour than was used in rearing the worms; when this I say, shall happen, and it is to be hoped it soon will, then the making of the Piedmontese reel more simple, and more familiar to the common people, will I believe appear a thing of considerable importance to our silk manufactures.

"I sometime ago turned my thoughts to the effecting of this; and should before now have put them in execution, had I not distrusted my own abilities to perform a thing, which the Piedmontese themselves had not attempted. I have now constructed a reel, which, without any additional mechanism, performs the work of the Piedmontese reel, and uses but two wheels with teeth instead of four wheels. It has been examined by some gentlemen in the silk-trade, who are well acquainted with the reels of that country, and allowed to work with much more simplicity, and greater perfection. Nor can I account why this improvement was not before attempted, but from the strong bias of habit confining the powers of invention.

"Some advantages, which this reel seems to have above the present Piedmontese reel, are, 1. that by a new proportion struck between the wheels, the silk thread will not be laid in the same place on the reel till after the winding of near six hundred yards: by which means, the thread having time to dry, all vitrage is avoided; whereas those now used do not reel above an hundred and fifty yards till the thread is laid in the same place.

"Secondly, I have added to this reel an improved method of making the double croissure in as easy a manner as the Piedmontese now make the single one; the double croissure giving a considerable perfection to the silk above what it obtains from the single one.

"As the limits to which I purpose confining this account will not allow of a more extended description, which, to gentlemen not versed in these matters, may already be thought too long, I shall avoid a greater trespass on your attention, by a brief reference to the annexed figure. (See plate CXVIII. fig. 2.)

"Fig. 1. represents the present Piedmontese reel. The position of the four wheels is shewn at A, B, C, and D: the toothed wheel A is fixed upon the axle of the reel; and, as the reel turns, it gives motion to the two wheels B and C, which are fixed upon one common arbre. The wheel C moves the wheel D, which is placed horizontal; and this, as it revolves, makes the guide-stick E F play forward and backward in a groove made in the upright G, the guide-stick playing freely on a pin E fixed in this wheel. Two threads of silk, drawn from two parcels of cocoons, which lie in the copper of hot water R, are passed through the two loops of the stop-wires K and L: they then are twisted round each other at M, which is the single croissure of the Piedmontese. At M they are again separated, and pass each through its own guide wire at N and P; and from these they go to the reel, where, as the reel turns, the motion of the guide-stick continually varies their position, and hinders them to be laid on the same place.

"Fig. 3. exhibits the new construction which I have given to this reel. The two wheels C and D of fig. 2. are laid aside as superfluous: the arbre Q passes through a nich in an upright supporter R, and, by a winch at its end A, gives motion to the guide-stick. The plane of its motion in the Piedmontese reel is horizontal, but here it is perpendicular. This perhaps made them think that the effect would not be the same; but it doth not cause any essential difference; and if it had, there was a most easy remedy for it.

"Here therefore the expence and trouble of making and adjusting two wheels and two sets of teeth are saved, the hazard of breaking and going out of order lessened, and the machine made more simple, and more familiar to the understanding.

"A shews the manner in which I have made a winch D, fixed in the arbre Q A, and answers the same purpose as the two wheels with teeth, which are used in the Piedmontese reel; by which the mechanism is rendered more simple, and the guide-stick F moved to the same advan-

tage as with the wheels. At *bb* are fixed two little ivory or brass wheels with smooth acute angled grooves in them to receive the threads which come from the two stop-wires *bb*. One end of the swivel cross K is somewhat broad, and rests upon the guide-stick F, directly in the middle between the two guide-wires *cc*. Here it moves and plays freely on a pin fixed in the guide-stick, the pin passing through the nich *m*. The other end of the swivel M contains the stop-wires *bb*, and is attached to the end of the rod O, which projects from the front bench of the reel. This attachment is made by means of a piece of packthread, with a knot on its end; which packthread passes through a hole in the swivel and in the piece O, and being fixed to a peg P, which turns in the under part of the piece O, is drawn to a proper degree of tension to allow, the swivel to obey all the motions of the guide-stick.

"The manner of making the double croissure is thus: the two silk threads are passed through the two stop-wires *bb*, and through the two guide-wires *cc*, and so are fastened to the reel. Then either of the two threads is taken in that part of it which lies between the stop-wire and guide-wire, and turned two or three times round the other thread; and then each thread is placed in the groove of the pulley at *bb*, taking care to place each in the groove of that pulley which lies on the side of its own stop-wire. The threads will then appear in the situation represented in the figure, twisted round one another in the two points *o* and *p*.

"The great advantage of this method is the taking off the pressure of the threads, by making them pass over two pulleys instead of two hooks; and by the swivel complying with all the motions of the guide-stick, which keeps the angles of the croissure constantly the same: without this, the bearing of the threads and the variation of the angles will make them so liable to break, that, from many experiments which I have made, I might venture to say, that though the double croissure has many advantages in compacting the silk thread, and shaking off its moisture, yet without such contrivance it will scarce ever be put in practice. I must also take notice, that this contrivance is vastly more simple than that which M. Vaucançon uses, though his has no one of these advantages." See the *Phil. Transf. for 1759. page 21.*

Raw SILK, that taken from the ball without fire, and wound without any coction; such is most, if not all, that is brought into England from the Levant.

Boiled SILK, that which has been boiled in water, to facilitate the spinning and winding.

Spider SILK.—In the year 1710, Mr. Bonn discovered a method of procuring and preparing silk of the webs of spiders, and using it in several manufactures.

After the death of Mr. Bonn, the French academy appointed the celebrated Reaumur to make a farther enquiry into this new silk work, who has raised several objections and difficulties against it, which are inserted in the *Memoirs of the Academy for the year 1710*. The sum of what he has urged amounts to this: the natural fierceness of the spiders, renders them unfit to be bred and kept together: four or five thousand being distributed into cells, 50 in some, 100, or 200 in others; the big ones kill and eat the less, so that in a short time there were left only one or two in each cell: and to this inclination of mutually eating one another Mr. Reaumur ascribes the scarcity of spiders, considering the vast number of eggs they lay.

But this is not all: he even affirms, that the spider's bag is inferior to that of the silk-worm, both in lustre and strength; and that it produces less matter to be manufactured. The thread of the spider's web only bears a weight of two grains without breaking; that of the bag bears 36. The latter, therefore, in all probability, is eighteen times thicker than the former; yet is it weaker than that of the silk-worm, which bears a weight of two drams and a half. So that five threads of the spider's bag must be put together to equal one thread of the silk-worm's bag.

Now, it is impossible these should be applied so justly over one another, as not to leave little vacant spaces between them, whence the light will not be reflected; and,

and, of consequence, a thread, thus compounded, must fall short of the lustre of a solid thread. Add to this, that the spider's thread cannot be wound off, as that of the silk-worm may; but must, of necessity, be carded; by which means being torn in pieces, its evenness, which contributes much to its lustre, is destroyed. In effect, this want of lustre was taken notice of by M. de la Hire, when Mr. Bonn presented a pair of stockings to the academy.

Again, spiders furnish much less silk than the worms: the largest bags of these latter weigh four grains; the smaller three grains; so that 2304 worms produce a pound of silk. The spiders bags do not weigh above one grain; yet, when cleared of their dust and filth, lose two thirds of their weight. The work of twelve spiders, therefore, only equals that of one silk-worm; and a pound of silk will require at least 27648 spiders. But as the bags are wholly the work of the females, who spin them to deposit their eggs in; there must be kept 52296 spiders, to yield a pound of silk. Yet will this only hold of the best spiders, those large ones ordinarily seen in gardens, &c. scarce yielding a twelfth part of the silk of the others. 280 of these, he shews would not do more than one silk-worm; and 663552 of them would scarce yield a pound.

SILK, in medicine, is very little used for medicinal purposes, though if the bags were burnt in a close vessel, they would undoubtedly prove a medicine of similar, and probably of superior virtue. They yield a larger quantity of volatile salt, than any other animal substance we know of; and the spirit of raw silk, rectified with some essential oil, makes the medicine known by the name of English drops.

SILLON, in fortification, an elevation of earth made in the middle of the moat, to fortify it, when too broad. It is generally called envelope.

SILVER, *Argentum*, in natural history, the finest and most fixed of all metals, except gold.

Silver is a soft, flexible metal, of little or no elasticity: by hammering it becomes moderately hard, elastic, and sonorous; more so than gold, less than copper or iron. Its specific gravity is to that of water nearly as 10 $\frac{1}{4}$ to 1. It melts in a bright red heat, a little sooner than gold; and when in fusion, appears a perfect speculum. Like gold, it continues ductile when heated as well as when cold; loses a little of its ductility by sudden cooling; proves brittle when heated by hammering; and regains its pristine malleability on being nealed, that is, slightly ignited and suffered to cool very leisurely. It seems to be perfectly fixed in the greatest degree of culinary fire; the small diminution, which in some experiments of this kind has happened at first, being apparently not of the silver itself, but of some other metal with which it had been debased.

Silver is the most perfect, ductile, and fixed in the fire, of all metals after gold. A single grain has been drawn into a wire three yards in length; and the wire flattened into a plate an inch broad. In common fires, it suffers no diminution of its weight; and kept in the vehement heat of a glass-house furnace for a month, it loses no more than one sixty-fourth. In the focus of Tschirnhaus's large burning-glass, it smokes for a long while, then contracts a greyish ash on the surface, and at length is totally dissipated. The proper menstruum of silver is the nitrous acid; which if well dephlegmated, will dissolve equal its own weight: the solution stains the skin black. It likewise stains hair, bones, and other solid parts of animals, and different kinds of wood, of all the intermediate shades, from a light brown to a deep and lasting black. The liquors commonly sold for staining hair brown or black, are no other than solutions of silver in aqua fortis, so far diluted with water as not sensibly to corrode the hair.

It gives a permanent stain likewise to sundry stones; not only to those of the softer kind, as marble; but to some of considerable hardness, as agates and jaspers. The solution, for this purpose, should be fully saturated with the metal; and the stone, after the liquor has been applied, exposed for some time to the sun. M. du Fay observes, in a paper upon this subject in the French Memoirs for the year 1728, that if the solution be repeat-

edly applied, it will penetrate, in the whitish agate or chalcedony, about one twelfth of an inch: that the tincture does not prove uniform, on account of veins in the stone: that the colours thus communicated by art are readily distinguishable from the natural, by their disappearing upon laying the stone for a night in aqua fortis; that on exposing it afterwards to the sun for some days, the colour returns: that the solution gave somewhat different tinctures to different stones; to the oriental agate a deeper black than to the common chalcedony; to an agate spotted yellow, a purple; to the jade-stone, a pale brownish; to the common emerald, an opaque black; to common granate, a violet unequally deep; to serpentine-stone, an olive; to marble, a reddish, which changed to a purple, and fixed in a brown: that on slates, talcs, and amianthus, it had no effect. Some have thought to increase the strength of the acid, by drawing it over from a quantity of fresh nitre; and been surprised to find, that instead of acting more powerfully upon silver, it would not now dissolve that metal at all, only corroding it into a white powder; and that on the other hand, it now proved a menstruum for gold, which before it had no effect upon. These alterations depend wholly upon the nitre containing sea salt; whose acid is expelled in the distillation by a part of the nitrous, and forced over along with the rest: pure spirit of nitre, drawn over from pure fresh nitre, dissolves silver, and leaves gold untouched, at first.

Solution of silver, evaporated a little, shoots in the cold into crystals, intensely bitter and corrosive, and hence called by some *fel metallorum*, the gall of metals: the crystallization is promoted by dropping in a little spirit of wine before the liquor is set to shoot. The crystals, or the solution inspissated to dryness, melt in a small heat, and form on cooling a dark-coloured mass still more corrosive, their phlegm having been dissipated in the fire. This mass is the lunar caustic or infernal stone of the shops: for the greater conveniency of using it as a caustic, it is commonly cast, in proper moulds, into slender cylindrical pieces. The crystals have been given internally, as purgatives and diuretics, and hence named catharticum lunare, and hydragogum angeli salæ: they are a medicine of great activity, too great to be taken with safety.

If solution of silver be diluted with pure water, a considerable quantity of pure mercury added, and the whole set by in a cold place; there will form by degrees a precipitation and crystallization resembling a little tree, with its root, trunk, and branches, called arbor Dianæ, or the philosophic silver-tree. Lemery gives another method of making an arbor Dianæ, by adding to solution of silver some warm distilled vinegar.

Crystals of silver readily dissolve in water; and by the assistance of warmth, in spirit of wine. Exposed for some time to a moderately strong fire, they part by degrees with all the acid, and return into silver again; though scarcely without some little loss, unless borax or alkaline fluxes are added, to collect or reunite the particles of the metal. If laid on a burning coal, the nitrous acid, deflagrating with the inflammable matter, as this acid in all its combinations does, is quickly consumed, and the silver revived. I have not, says Mr. Lewis, observed in this experiment any considerable volatilization of the silver; though in the *Acta Naturæ Curiosorum*, tom. VI. there is a remarkable history of silver dissolved in the nitrous acid being volatilized in close vessels by means of charcoal. Four ounces of pure silver being dissolved in aqua fortis, and the solution set, to distil in an earthen retort; a white transparent butter arose into the neck, and nothing remained behind: by degrees the butter liquefied, and passed down into the phlegm in the receiver: the whole being now poured back into the retort, the silver arose again along with the acid: on adding sea salt to this volatilized solution, the silver was precipitated into a luna cornea. The volatilization being attributed to the liquor having stood in an elaboratory where charcoal was bringing in, the experiment was repeated with a fresh solution of silver mixed with a little powdered charcoal, with the same event.

Another kind of artificial vegetation, as it is called, may be produced, by spreading a few drops of solution

of silver upon a glass-plate; and placing in the middle a small bit of any of the metals that precipitate silver, as particularly of iron. The silver quickly concretes into curious ramifications all over the surface of the plate. Other metallic solutions afford also vegetations on the same treatment; but none so elegant ones as that of silver.

Silver is precipitated from aqua fortis by all the metals which dissolve in that acid, readily and copiously at first, but slowly and difficultly towards the end. The menstruum generally retains some portion of the silver, as the silver almost always does of the metal which precipitated it. The refiners, for recovering the silver from aqua fortis after parting, employ copper. The solution, diluted with water, is put into a copper vessel, or into a glass one with thin plates of copper, and set in a gentle warmth; the silver begins immediately to separate from the liquor in form of fine grey scales or powder; a part of the copper being dissolved in its place, so as to tinge the fluid more and more of a bluish green colour: the plates are now and then shaken, that such part of the silver, as is deposited upon them, may fall off and settle to the bottom. The digestion is continued, till a fresh bright plate kept for some time in the warm liquor, is no longer observed to contract any powdery matter on the surface; when the liquor is poured off, and the precipitate washed with fresh parcels of boiling water. The small portion of silver, which the acid commonly still retains, may be precipitated by common salt: the copper which the silver retains may be in part scorified and separated by fusion with nitre. It is observable, that though the acid, in this process, saturates itself with the copper in proportion as it lets go the silver; yet the quantity of copper which it takes up, is not near so great as that of the silver which it deposits. One dram of copper will precipitate three of silver, and saturate all the acid that held the three drams dissolved.

Absorbent earths, as chalk, or quick-lime, throw down a part of the silver, but leave a very considerable part suspended in the liquor. If the earth be moistened with the solution into the consistence of a paste, and exposed to the sun, it changes its white colour to a dark purplish black: distinct characters may be exhibited on the matter, by intercepting a part of the sun's light by threads, slit paper, &c. placed on the outside of the glass. Culinary fire does not affect its colour: after the mass has been exsiccated by this, it changes as before upon being exposed to the sun.

Volatile alkaline spirits, added to a solution of silver, precipitate little. Pure fixed alkalies, and alkalies rendered caustic by quick-lime, throw down the whole. Fixed alkalies impregnated with inflammable matter, by calcination with animal coals, occasion at first a considerable precipitation, but if added in larger quantity, take up great part of the metal again. Mr. Marggraf relates, that adulterated calces of silver totally dissolve both in a lixivium of these alkalies, and in volatile spirits; and that the marine acid precipitates the silver from the volatile, but not from the fixed alkaline solution. Kunckel reports, that the calx precipitated by volatile spirits made with quick-lime, fulminates or explodes in the fire: and that by inspissating a solution of pure silver, melting the dry residuum, pouring on it spirit of urine, supersaturated with salt, and setting the mixture in a gentle warmth, a blood-red mass is produced, so tough as to be wound about the fingers.

The marine acid does not dissolve silver, but precipitates it from the nitrous. Upon adding to a solution of the metal made in aqua fortis, either the pure acid of sea salt, or the salt in substance, or sal ammoniac, the liquor instantly becomes milky, and, on standing, deposits the silver now combined with the marine acid into a white powder. This, when sufficiently washed with water, proves insipid, though containing so much acid as to weigh one fourth more than the silver employed. It does not dissolve in water, spirit of wine, aqua fortis or aqua regis; but is in some small degree red hot, and on cooling forms a ponderous brownish mass, which if cast into thin plates proves semi-transparent, and somewhat flexible, like horn: whence its name *luna cornea*. A stronger fire does not expel the acid from the silver; the whole

concrete either arising in fumes, or sinking through the vessel without any separation of its parts: it may be sublimed like arsenic, with which it has, in many respects, a great analogy. If mixed with fixed alkaline salts, or inflammable substances, as oil or tallow, and melted in a crucible, the acid is absorbed or expelled, and the silver recovered pure.

The vitriolic acid also precipitates silver from the nitrous; but does not act upon silver in its metallic state, unless highly concreted and assisted by a boiling heat. The marine acid precipitates silver from the vitriolic, in the same manner as from the nitrous.

Luna cornea is most commodiously prepared, by diluting a solution of silver with ten or twelve times its quantity of water, and adding, by degrees, a solution of sea salt, so long as it occasions any turbidness or milky hue. The whole is then to be set by till the white powder has settled; when the clear liquor is to be poured off, and the precipitate washed with fresh parcels of boiling water. If the silver contained any portion of copper, which it always does after the common methods of purification, that metal will here be separated, and left dissolved in the liquor; pure sea salt precipitating no metallic body but silver, lead, and mercury. Hence silver is brought, by this process, to a degree of purity scarce procurable by any other known means.

The silver may be recovered from the luna cornea, by fusion with alkaline and inflammable fluxes, or with certain metallic bodies; but in these operations, there happens always a considerable loss of the silver; a part of the volatile calx being dissipated by the fire, before the alkali or metal can absorb its acid. Mr. Marggraf has discovered a method of reviving the silver with little or no loss; mercury, assisted by volatile salts, imbibing it by trituration without heat. One part of luna cornea and two of volatile salt are to be ground together in a glass mortar, with so much water as will reduce them to the consistence of a thin paste, for a quarter of an hour or more: five parts of pure quicksilver are then to be added, with a little more water, and the triture continued for some hours. A fine amalgam will thus be obtained; which is to be washed with fresh parcels of water, so long as any white powder separates. Nearly the whole of the silver is contained in the amalgam, and may be recovered perfectly pure by distilling off the mercury: the white powder holds also a small proportion, separable by gentle sublimation; the matter which sublimes is nearly similar to mercurius dulcis.

Luna cornea totally dissolves in volatile alkaline spirits, without any separation of the metal. Exposed to the fire in a close copper vessel, it penetrates the copper, and tinges it throughout of a silver colour. Kunckel observes, that when carefully prepared, melted in a glass vessel, and suffered to cool slowly, to prevent its cracking, it proves clear and transparent, may be turned in a lathe, and formed into elegant figures. He supposes this to be the preparation which gave rise to the notion of malleable glass.

Mercury very readily amalgamates with silver leaf. It easily unites likewise with the calx of silver, precipitated by copper: but does not touch the calces precipitated by salts.

The vapours of sulphureous solutions stain silver yellow or black. Sulphur melted with silver debases its colour to a leaden hue, renders it more easily fusible than alone, and makes it flow so thin, as to be apt, in a little time, to penetrate the crucible: in a heat just below fusion, a part of the silver shoots up, all over the surface, into capillary efflorescences. Aqua fortis, the solvent of pure silver, does not act upon the silver in this compound; but fixed alkaline salts, the menstruum of sulphur, may be made to absorb that ingredient; the alkali, however, when combined with the sulphur, will take up the silver again. If the sulphurated silver be mixed with mercury sublimate, and exposed to the fire, the mercury of the sublimate will unite with the sulphur, and carry it up in the form of cinnabar, whilst the marine acid of the sublimate unites with the silver into a luna cornea, which remains at the bottom of the glass: fire alone, continued for some time, is sufficient to expel the sulphur from silver.

Silver is purified from the baser metals by cupellation with lead. It always retains, however, after that operation, some small portion of copper, sufficient to impregnate volatile spirits with a blue tincture, which some have erroneously supposed to proceed from the silver itself. It is purified from this admixture by melting it twice or thrice with nitre and borax: the scorix, on the first fusion, are commonly blue; on the second, green; and on the third, white, a mark of the purification being completed. But the most effectual purification is the revival of silver from luna cornea.

Silver is purified and whitened extremely by boiling in a solution of tartar and common salt. This is no other than an extraction of the cupreous particles from the surface of the silver, by the acid of the tartar acuated with the common salt.

The silver employed for coins and utensils have always an admixture of copper, which improves its hardness and sonorousness. Its degree of fineness is expressed among us by loths or half ounces: a marck contains sixteen half ounces; the silver is said to be of sixteen loths, when all the sixteen half ounces are pure silver; of fifteen, when only fifteen half ounces are pure silver, and the other copper, &c. — Most of the other metallic bodies render it brittle; one part of tin destroys the malleability of above an hundred parts of silver; and regulus of antimony has this effect in a still greater degree. Both regulus of antimony and arsenic render a part of the silver volatile in the fire.

Silver discovers, in some circumstances, a great attraction to lead; though it does not retain any of that metal in cupellation, as gold does. If a mixture of silver and copper be melted with lead, in certain proportions, and the compound afterwards exposed to a moderate fire, the lead and silver will melt out together, bringing very little of the copper with them: by this method, silver is often separated from copper in the large works. The effect does not depend wholly upon the different fusibility of the metals; for if tin, which is still more fusible than lead, be treated in the same manner, with a mixture of copper and silver, there will be no eliquation; the three ingredients here strongly attracting one another, so as to come all into fusion together. Again, if silver be melted with iron, and lead added to the mixture, the silver will forsake the iron to unite with the lead, and the iron will float by itself on the surface.

Precipitates or calces of silver melted with vitreous substances, impart to them a yellow colour. Kunckel observes, that when the glass is strongly stirred in fusion with an iron rod, or blown into vessels, it changes its uniform tinge into an opaque milkiness, variegated with yellow and other colours: the preparation of silver he employs is luna cornea. This, or the other precipitates, spread upon a glass plate, adhere and stain it yellow by ignition with fusion: hence their use in painting on glass.

The most beautiful enamel for porcelane hitherto discovered, communicated in the Philosophical Transactions, and the Swedish Acts, owes its colour to silver. A glass made from three parts of litharge and one of flint, is reduced into gross powder, and a solution of about one twentieth its weight of silver poured upon it: the mixture is stirred together, exsiccated and melted again, and when in thin fusion poured out. This composition, ground into fine powder, is applied on the porcelane previously heated; and the ignition continued under a muffle, till the powder melts, which is known by its glistening. The ware is then taken out of the furnace, and, whilst it continues red-hot, held over the smoke of burning vegetables, which calls forth the beautiful colour.

Silver is found in all countries; but most plentifully in America, particularly in Peru and Potosi, from whence large quantities are brought annually into Europe. It is met with either in its perfect metallic state, or in the form of ore, or blended in the ores of other metals.

Native malleable silver occurs not unfrequently in different stones, earths, and in most kinds of sands, in small pieces, of different figures, chiefly filaments or scales. It generally contains somewhat arsenical, but never holds any gold, though native gold is seldom free from silver.

The principal ores of silver are, 1° Ganskoethig ertz, goose-dung ore, so called from its colour; this is surrounded, and penetrated with efflorescences of capillary silver. 2° Glassertz, composed of silver and sulphur: this ore is of an irregular figure, sometimes cubical, sometimes of eight or more sides. When pure, it may be hammered or cut almost like lead; but if penetrated by foreign matters, it falls in pieces from a blow; the pieces singly prove malleable. There are some sorts brittle throughout, probably from an admixture of arsenic; its colour is blackish, sometimes brighter and sometimes darker: there is one sort of a grey colour, almost like the fallow ore, but differing from that ore in containing no copper: it melts in the fire as soon as it begins to grow red-hot: its yield of silver is variable, but always large, amounting commonly to about three-fourths of its weight. 3° Hornertz, horn ore; externally irregular, internally composed of fine leaves laid together, and semi-transparent like horn. It yields like the foregoing both to the hammer and the knife: its colour is whitish, yellowish, or brownish: it is commonly foul on the outside, but may be easily distinguished by cutting or bending it. In the fire it emits both an arsenical and sulphureous fume, and commonly affords two thirds its weight of silver. 4° Rothgulden ertz, red silver ore, is sometimes of a deep transparent red, and sometimes darker: it is distinguished from cinnabar by its colour inclining not to an aurora or brick red, but to the garnet or ruby red, or a purple red; though there are red silver ores also of a dull brick hue: the colour of cinnabar is improved, but that of the silver ores debased, by grinding them into fine powder. This ore is very ponderous, melts in the fire before it becomes red-hot, and emits thick fumes smelling strongly of arsenic. It consists of silver and arsenic, with a little sulphur; and with these ingredients, or with equal parts of arsenic and native silver, it may be imitated by art. The quantity of silver in the deep red sorts is commonly from sixty to sixty-two pounds on the hundred: the yield of the darker kinds is inconstant: these last hold commonly a little iron. 5° Weissguldenertz, white silver ore, is of a bright grey colour, ponderous and brittle; when pure, it contains seven pounds of silver on the hundred, but a larger quantity of copper. It consists of silver, copper, antimony, arsenic, and sulphur: several sorts contain likewise iron, and hold but very little silver, as two ounces on the hundred-weight; these are of a paler and brighter colour than the others, and called plain Weissertz, white ore. The white silver ores have a great resemblance in colour to the paler cobalts; these last however are sensibly whiter, and incline a little, like bismuth, to a reddish or yellowish cast. 6° The Fahlerz and Fahlguldenerts, fallow ore and fallow copper ore, are ranked among the ores of silver, though they belong more properly to those of copper. Their colour is a dark grey; they are found among and sometimes blended with copper ores and copper pyrites: they hold from four ounces to some pounds of silver upon the hundred. 7° Federertz, feather ore, is composed of extremely fine fibres or hairs: it holds two ounces of silver on the hundred-weight, and contains both arsenic and sulphur, for it yields on sublimation a yellow arsenic. 8° Rufs, sooty ore, consists of a fine soft black dust, which is commonly lodged in clefts: it is very rich in silver, yielding sometimes half its weight.

The method of extracting SILVER from the Ore.—In order to extract silver from the ore, they first break it into pretty small pieces, and then grind it with iron pestles, weighing about two hundred pounds, and which commonly are moved by water. The ore, when pounded, is passed through a sieve of iron or copper, and then kneaded with water to a paste, which they leave to dry a little; afterwards they knead it a second time with sea salt; and at last they throw some mercury upon it, and knead it a third time, in order to incorporate the mercury with the silver; being what they call an amalgama. Eight or ten days are sufficient for this process in temperate places; but in cold countries it sometimes requires a month or six weeks: they then throw the paste into large tubs or lavatories. In order to facilitate the operation, they constantly stir the paste with their feet, that when the water

comes clear out of the basons, there may remain at the bottom only silver and mercury amalgamated together; and this is what they call pigna. They endeavour to extract the mercury which is not incorporated with the silver, by pressing the pigna, beating it strongly, or bruising it in a press or mill. There are pignas of different sizes and different weights; they commonly contain a third of silver, and two thirds of mercury. They lay the pigna upon a trevet, placing under it a vessel full of water; and cover the whole with earth, in form of a cap, which they surround with burning coals. The action of the fire causes the mercury to evaporate from the pigna, and falls into the water, where it is condensed. The interstices which the mercury occupied in the pigna continue empty, and there remains only a porous and light mass of silver, compared with its former bulk.

Silver is likewise extracted from the ore in the following manner: they first break the ore, and sometimes wash it, to separate the stony particles which have been reduced to a powder: after this they calcine it, in order to extract from it the sulphur and arsenic: this is what they call roasting the ore; after which they wash it again, to free it from the calcined powder. The ore being thus prepared, they fuse it with lead or litharge, or with copel-heads that have been used before; they employ granulated lead for this purpose, when the work is but small. The harder the ore is to melt, the more lead they mix with it, about fifteen or twenty parts of lead to one of ore. This process is called scorifying: the scorizæ consist of lead vitrified with the stone, and with whatever else is not gold or silver in the ore; and the metal precipitates into a regulus. If this regulus look pretty fine, and of a metallic colour, they put it into the copel; but, if it still be mixed with scorizæ, and black, they melt it over again with a small quantity of glass or lead.

In order to separate the silver from the mercury, with which it is amalgamated, they have a furnace with an aperture at the top; this aperture they cover with a sort of dome made of earth in a cylindrical form, which may be kept on or taken away at pleasure. When they have put the mass of silver and mercury into the furnace, laid on the cover, and lighted the fire, the quicksilver rises in the form of vapours, and adheres to the dome, from whence they collect it, and use it again for the same purpose.

When the silver is well purified, so that all heterogeneous matter, either metallic or other, that might be mixed with it, is extracted, they say it is twelve carats fine. This is the expression they use to denote the quality of the purest silver, without any mixture or alloy; but, if there should remain any, they deduct the weight of the mixture from the principal weight, and the remainder shews the value of the silver. The carat consists of twenty-four grains: so that, when to the weight of twelve carats there are twelve grains of mixture, the value of the silver is eleven carats twelve grains: and so of any other.

Refining of SILVER. See REFINING.

SILVER-LEAF, that beaten out into fine leaves for the use of the gilders, which is performed in the same manner as gold leaf.

Shell-SILVER, is made with silver leaf ground with new honey, and, after pouring a small quantity of aqua fortis on it, the menstruum is poured off, and the silver kept for use.

SILVERING, the covering of any thing with silver. It is usual to silver metals, wood, paper, &c. which is performed either with fire, oil, or size. Metal-gilders silver by the fire; painter-gilders all the other ways.

To silver copper or brass: 1. Cleanse the metal with aqua-fortis, by washing it lightly, and immediately throwing it into fair water; or by heating it red-hot, and scouring it with salt and tartar, and fair water, with a small wire-brush. 2. Dissolve some silver in aqua-fortis, in a broad-bottomed glass vessel, or of glazed earth, then evaporate away the aqua-fortis over a chaffing-dish of coals. 3. Put five or six times its quantity of water, or as much as will be necessary to dissolve it perfectly, on the remaining dry calx; evaporate this water with the like heat; then put more fresh water, and evaporate

again; and if need be, the third time, making the fire towards the latter end so strong, as to leave the calx perfectly dry, which, if your silver is good, will be of a pure white. 4. Take of this calx, common salt, crystal of tartar, of each a like quantity, or bulk, and mixing well the whole composition, put the metal into fair water, and take of the said powder with your wet fingers, and rub it well on, till you find every little cavity of the metal sufficiently silvered over. 5. If you would have it richly done, you must rub on more of the powder, and in the last place wash the silvered metal in fair water, and rub it hard with a dry cloth.

SILVESTRE, or **SYLVESTRE**, *granum*, or *coccus SYLVESTRI*, a term used by some authors, to express the *coccus Polonicus*, and by others, for a coarse or bad kind of cochineal, produced in the province of Guatemala, in New Spain: it is by some supposed to be the seed of the plant; but it is, in reality, a true insect as the cochineal is; only that the scarlet colour it yields, is greatly inferior to the other.

SIMATIUM, or **SIMAISE**, in architecture. See **CYMATIUM**.

SINNA, the **MONKEY**. See the article **MONKEY**.

SIMILAR Arches of a Circle, are such as are like parts of their whole circumferences.

SIMILAR Bodies, in natural philosophy, are called such as have their particles of the same kind and nature one with another.

SIMILAR plane Numbers, are those numbers which may be ranged into the form of similar rectangles: that is, into rectangles whose sides are proportional, such are 12 and 48; for the sides of 12 are 6 and 2, and the sides of 48 are 12 and 4. But $6:2::12:4$, and therefore those numbers are similar.

SIMILAR Polygons, are such as have their angles severally equal, and the sides about those angles proportional.

SIMILAR Rectangles, are those which have their sides about the equal angles proportional.

1. All squares are similar rectangles.

2. All similar rectangles are to each other as the squares of their homologous sides.

SIMILAR Right-Lined Figures, are such as have equal angles, and the sides about those equal angles proportional.

SIMILAR Segments of a Circle, are such as contain equal angles.

SIMILAR Conic Sections. Two conic sections of the same kind are said to be similar, when any segment being taken in the one, we can assign always a similar segment in the other.

SIMILAR Diameters of two Conic Sections. The diameters in two conic sections are said to be similar, when they make the same angles with their ordinates.

SIMILAR Solids, are such as are contained under equal numbers of similar planes, alike situated.

SIMILAR Triangles, are such as have all their three angles respectively equal to one another.

1. All similar triangles have the sides about their equal angles proportional.

2. All similar triangles are to one another as the squares of their homologous sides.

SIMILAR DISEASE, in medicine, denotes a disease of some simple, solid part of the body; as of a fibre with regard to its tension or flaccidity; of a membrane; a nervous canal, or the like.

SIMILAR-PARTS, in anatomy, are those parts of the body which at first sight appear to consist of like parts, or parts of the same nature, texture, and formation; of these we usually reckon ten, viz. the bones, cartilages, ligaments, membranes, fibres, nerves, arteries, veins, flesh, and skin. See **BONE**, **CARTILAGE**, &c.

SIMILE, or **SIMILITUDE**, in rhetoric and poetry, a comparison of two things, which, though different in other respects, yet agree in some one. — As, "He shall be like a tree planted by the water-side, &c."

SIMILITUDE, in arithmetic, geometry, &c. denotes the relation of two things similar to each other.

SIMONICAL, is applied to any person guilty of simony.

SIMONIANS,

SIMONIANS, in church history, a sect of ancient heretics, so called from their founder Simon Magus, or the magician.

Simon Magus was a Samaritan, born in the village of Gitton. St. Philip the deacon, coming to preach at Samaria, converted several persons there, and among the rest this Simon, who believed, and was baptized. When the apostles St. Peter and St. John came to Samaria, and had conferred the Holy Ghost on such as had been baptized by Philip, Simon, full of amazement at seeing the wonderful effects of the apostles imposition of hands, offered them money, on condition they would give him the same power: for which he received a very sharp and severe rebuke from St. Peter. The author of the Acts of the Apostles adds, that Simon had before addicted himself to the practice of magic, and by his impostures and enchantments had seduced the people of Samaria, who all followed him as a person endowed with a divine and supernatural power.

After St. Peter's reproof, and refusal to sell him the power of imparting the Holy Ghost, Simon fell into much great errors and abominations, applying himself to magic more than ever, and taking a pride in withstanding the apostles. For this purpose he left Samaria, and travelled through several provinces, seeking out such places where the Gospel had not yet been preached, that he might prejudice the minds of men against it. At Tyre in Phœnicia, he bought a public prostitute, named Sclene or Helene, whom he carried about with him wherever he went, pretending she was that Helen who had occasioned the Trojan war.

Having run through several provinces, and gained the admiration of a vast number of persons, he came to Rome, in the time of the emperor Claudius, about the year of Christ 41. It is said, he was honoured as a god by the Romans, and that the senate decreed a statue to be erected to him in the isle of the Tyber, inscribed **TO SIMON THE HOLY**. The fact however is disputed by the best critics, who think that Justin Martyr mistook an image of Semo Sanctus, a Pagan deity, for one erected to Simon Magus.

St. Peter, coming to Rome some time after the arrival of Simon Magus, soon reversed all that the impostor had been doing there. However, Simon did not quit that city, but continued to spread his errors, and, under the reign of Nero, again acquired a great reputation by his enchantments. He pretended to be the Christ, and that he could ascend into heaven. And we are told, he raised himself up into the air in a fiery chariot, by the assistance of magic art. But St. Peter and St. Paul at the same time betaking themselves to prayer, his charms failed him, and falling to the ground he broke his legs. Being carried to Brundisium, he there threw himself from the top of the house where he lodged, and died on the spot.

The heresies of Simon Magus were principally, his pretending to be the great power of God, and thinking that the gifts of the Holy Ghost were venal, and to be purchased with money. He is said to have invented the *Æons*, which were so many persons, of whom the Godhead was composed. His concubine Helen he called the first intelligence, and mother of all things; and sometimes he called her Minerva, and himself Jupiter.

Simon Magus had gained a great number of followers, who embraced all the principles of their master, and indulged themselves in all sorts of vices and irregularities. They paid divine worship to Simon and Helen, offering to them victims and libations of wine. There is no doubt that, when St. John, St. Peter, and St. Paul, in their epistles, warn the Christians against heretics, false apostles, and false teachers, the Simonians are principally intended. And indeed, as they were the earliest heretics, so were they the source of most of the other heretics, which soon after sprung up in the church.

The sect of the Simonians continued down to the fourth century. Origen tells us, they were reduced to about thirty persons; and elsewhere, that they were quite extinct.

SIMONY, in ecclesiastical law, the crime of buying or selling spiritual gifts or preferments. In the antient

Christian church, this crime was always thought to be committed when men either offered or received money for ordinations. The apostolical canons lay a double punishment both of deposition and excommunication, on such of the clergy as were found guilty of it. This was the first sort of simony, and that which was most properly so called; and to this the antients reduced the exacting of any reward for administering the eucharist or baptism, or for any spiritual offices. A second sort of simony consisted in buying the spiritual preferments of the church; this was punished with deposition in any bishop who promoted any church-officer for the sake of lucre; and the persons so promoted, were to be degraded from their office. By the laws of Justinian, every elector was to depose upon oath, that he did not chuse the person elected for any gift or promise, or friendship, or any other cause, but only because he knew him to be a man of the true catholic faith, of unblameable life, and good learning. This last sort of simony was, when men by ambitious arts and undue practices got themselves invested in an office or preferment to which they had no regular call, or when they intruded themselves into other mens places, which were legally filled before. The casuists for the church of Rome maintain, that all compacts or bargains in which benefices are concerned, are simoniacal, when it is done without the pope's concurrence; but that, once obtained, gives a sanction to the thing, which they found upon this universal proposition, that the pope cannot commit simony in beneficiary matters, since he hath a power so absolute over all the ecclesiastical goods and benefices, that he can unite, divide, and bestow them in whatever manner he pleases.

Against the corruption of simony, there have been many canons made in our own church, which punish the offender with deprivation, disability, &c. and by a statute of the 31 Eliz. it is enacted, that if any person for any sum of money, reward, gift, profit, or benefit, or by reason of any promise, agreement, grant, bond, covenant, or other assurance, shall present, or collate any person to any benefice with cure, dignity, or living ecclesiastical, every such presentation, or collation, and every admission or induction thereupon, shall be utterly void, and the crown shall present for that turn; and the person that shall give or take any sum of money, &c. shall forfeit double the value of one year's profit of any such benefice; and the person so corruptly taking any such benefice, shall from thenceforth be disabled to have and enjoy the same.

SIMPLE, something not mixed or compounded; in which sense it stands opposed to compound.

Thus we say, simple form, simple mode, simple fee, simple force, simple equation, simple anomaly, simple glands, simple vision, simple flank, simple fraction, &c.

SIMPLE, in botany, is a general name given to all herbs and plants; as having each its particular virtue, whereby it becomes a simple remedy.

SIMPLE CONCORDS, are those wherein we hear at least two notes in consonance; as a third and fifth; and, of consequence, at least three parts.

SIMPLE COUNTER-POINT, is a harmonical composition, wherein note is set against note; in opposition to figurative counter-point.

SIMPLEX BENEFICIUM, signifies an inferior dignity in a cathedral or collegiate church, a sine-cure, pension, or any ecclesiastical benefice, opposed to a cure of souls, and which therefore is consistent with any parochial cure, without coming under the denomination of pluralities.

SIMPLIFYING, in ecclesiastical matters, is the taking away the cure of souls from a benefice, and dispensing the beneficiary from residence.

SIN, a breach or transgression of some divine law, or command.

SINAPI, or **SINAPIS**, mustard, in botany, a genus of plants, the corolla of which consists of four cruciform, roundish, plane, patent, and entire petals, with erect linear unguis, and scarcely the length of the cup; the fruit is an oblong, rough pod, consisting of two valves

valves, and containing two cells: the seeds are numerous and globose.

Mustard-seed is an attenuant and resolvent in a very high degree; it warms the stomach, and excites an appetite; but its principal medicinal use is external in sinapisms, applications made to certain parts when irritation is intended, but not blistering. It is usually mixed with horse-radish root, and other ingredients of the same kind, for this purpose.

SINAPISM, in pharmacy, is a cataplasm of mustard-seed applied with a view of exciting a heat and redness of the skin.

SINCIPUT, in anatomy, the fore-part of the head, reaching from the forehead to the coronal suture.

SINDON, in surgery, a little round piece of linen, silk, or lint, used in dressing a wound after trepanning.

SINE, or *right SINE of an Arch*, in trigonometry, is a right-line drawn from one end, or termination of an arch, perpendicular to the radius drawn to the other termination of the arch; being always equal to half the chord of twice the arch. Thus, SR , plate CXIX. *fig. 1.* is the right sine of the arches SA and SD . See CIRCLE.

Whole SINE, *sinus totus*, the sine of 90 degrees, being equal to the radius or semidiameter.

SINE Complement, or *co-SINE of an Arch*, is that part of the diameter intercepted between the center and sine, and is equal to the sine of the complement of that arch. Thus CR is the co-sine of the arch AS , and equal to HS , the sine of its complement BS .

Verfed SINE of an Arch, is the part of the diameter intercepted between the sine and the periphery. Thus, RA is the verfed sine of AS , and of BS .

SINE-CURES, ecclesiastical benefices without cure of souls.

SINEW properly denotes what we call a nerve; though, in common speech, it is rather used for a tendon.

SINGING, the action of making divers inflexions of the voice, agreeable to the ear, and correspondent to the notes of a song, or piece of melody.

The first thing to be done in learning to sing, is to raise a scale of notes by tones and semi-tones to an octave, and descend by the same notes; and then to rise and fall by greater intervals, a third, fourth, fifth, &c. and to do all this by notes of different pitch. Then these notes are represented by lines and spaces, to which the syllables *fa, so, la, mi*, are applied, and the pupil taught to name each line and space thereby; whence this practice is called *sol-faing*.

SINGULAR NUMBER, in grammar, the first manner of declining nouns, and conjugating verbs; used when we only speak of a single person or thing.

The Latins, French, English, &c. have no number but the singular and plural; the Greeks and Hebrews have likewise a dual.

SINGULTUS, in medicine, a convulsive motion of the midriff, commonly called hiccup. See the article HICCUP.

SINICAL QUADRANT. See the article *Sinical QUADRANT*.

SINISTER, something on, or towards, the left hand. Hence, some derive the word *finister a sinendo*, because the gods, by such auguries, permit us to proceed in our designs.

SINISTER, in heraldry. The sinister side of an escutcheon is the left hand side; the sinister chief, the left angle of the chief; the sinister base, the left hand part of the base.

SINISTER ASPECT, among astrologers, is an appearance of two planets happening according to the succession of the signs, as Saturn in Aries, and Mars in the same degree of Gemini.

SINISTRI, a sect of ancient heretics, thus called, because they held the left hand in abhorrence, and made it a point of religion not to receive any thing therewith.

SINKING FUND, a provision made by parliament, consisting of the surplussage of other funds, intended to be appropriated to the payment of the national debts; on the credit of which very large sums have been borrowed for public uses.

SINOPLE, or SENOPLE, in heraldry, denotes vert, or the green colours in armories.

SINUATED LEAF, in botany, a leaf which has a number of sinuses on its side, but those separated by lobes, not very long, nor themselves indented, or notched at the edges. *Sinuato-dentated-leaf*, expresses a leaf like the former, but with the lateral lobes of a linear figure.

SINUOSITY, a series of bends and turns in arches, or other irregular figures, sometimes jetting out, and sometimes falling in.

SINUOUS ULCER. See ULCER.

SINUS, in anatomy, denotes a cavity in certain bones, and other parts, the entrance of which is very narrow, and the bottom wider and more spacious. Of these sinuses we find several in divers parts of the body, particularly in the internal surface of the os occipitis; in adults, there is a cross, to which adheres the sinuses and processes of the dura mater, the use of which is to carry the blood from the brain, by a very peculiar mechanism, under the sella equina, or turcica of the os sphenoides; there is also a sinus called the sphenoidal sinus; this is sometimes double, and opens into the nostrils; sometimes it is totally wanting.

Sinus of an artery is used, by some, for any part of an artery where its sides are stretched out beyond the ordinary proportional dimensions elsewhere. Morgagni has observed four such sinuses in the aorta, three of them answering to the semilunar valves; and the fourth is all that part of the aorta between the former sinuses, and the origin of the common trunk of the right subclavian and carotid arteries. Sinus of the womb is used for any cavity within its substance. See UTERUS.

SINUS, in surgery, a little cavity, or sacculus, frequently formed by a wound or ulcer, wherein pus is collected.

A sinus is properly a cavity in the middle of a fleshy part, formed by the stagnation and putrefaction of the blood or humours, and which has wrought itself some vent or exit.

SIPHON, or SYPHON, in hydraulics, a bended pipe, one end of which being put into a vessel of liquor, and the other hanging out of the said vessel over another, the liquor will run out from the first into the last, after the air has been sucked out of the external or lower end of the siphon, and that as long as the liquor in the upper vessel is above the upper orifice of the siphon. Thus, HDS , plate CXIX. *fig. 2.* is a siphon whose two parts HD , DS , are called its legs, and by its operation, the water is drawn out of the upper vessel $ABCD$, into the lower ab . When you have sucked out the air at S , the water follows, coming in at H , going in the direction $HGDS$, and out at S , as long as the surface EF is above IH ; the level of the mouth of what is called the driving leg of the siphon, being that in which the water goes up, as that through which it goes down is called the issuing leg, and is always longer than the driving leg. Now, the cause of the siphon's running is this. The air which presses into the vessel $ABCD$, represented by the column KL , sustains the column of water LD , in the short leg of the siphon, pressing against that air with its perpendicular height DF , whilst the column of air MS , pressing upwards against the hole of the long or issuing leg DS , which acts according to the height DC , must yield and suffer the water to run out as long as the leg DS is longer, or rather higher in perpendicular than DG . For since K and M are supposed at top of the atmosphere, the column KL and MS are equal in height and pressure, the height of L above S being of no account in the height of the atmosphere as long as MS is acted upon by the descending water DS , whose height is from D to S , suppose fifteen inches, an height superior to that of the column DG , suppose of seven inches, supported by the column of air KL , the column MS must yield to the water issuing out at S ; and however the surface of the water $E-F$ descends, the column KL , by its pressure, will always overcome the resistance of the column MS , because it has a less height of water to sustain than MS has. If the mouth of the issuing leg had been at T , the water would hang in equilibrio, filling both legs of the siphon, when

when the water is come down in the upper vessel to I H T, because then the two columns of air K L and M S will be acted against by an equal height of water in the legs of the siphon; but if then you raise the issuing end of the siphon, now supposed at T, up to the level of π V above I H, the water will run back up from V to D; and so out at H, in the upper vessel, because then the column M S having only the height V D to sustain, will be acted against with less force than the column K L, which is pressed against by the whole height D H, superior to V D. See the articles FLUID, ENGINE, AIR, &c.

Since the pressure of the air is the cause of the water being pushed up into the siphon, and the difference of its pressure, as one column is acted against by the water in the short leg more weakly than another column of air is acted upon by the water in the long leg, is the cause of its running continually from one vessel into another, when once set a-going, it follows, that the bend D of the upper part of the siphon must not be above thirty-two feet higher than the water in the upper vessel, because the air cannot sustain a column of water, whose height exceeds thirty-two feet. If therefore there was a crane, or siphon, A C E D B (fig. 3.) of about forty feet high, reckoning from A to E, with cocks A and B at its lower ends, and an hole at the top E, to be stopped with a cork upon occasion, there might be made the following experiment; water being poured into the vessels A and B, let the cocks A and B be shut; then with a funnel pouring in water at E, till both legs of the siphon are full, stop the hole E, and open the two cocks at once. The water, instead of running from the vessel A into B, which it would do if the height C A was much under thirty-two feet, will in the two legs fall back to C and D thirty-two feet above A and B, where it will hang, the air not being able to sustain the water above those heights, and consequently to drive it up over the bend E. Nay, unless the water be purged of air before the experiment, the top of the water at C and D will not be quite thirty feet above the water in the vessels A and B, because air will extricate itself out of the water, and getting into the cavity C E D, press a little on the top of the water at C and D, so that its height will be less to ballance the pressure of the atmosphere.

Mercury will run in a siphon in the same manner as water, but then the bend of the siphon must not be more than thirty inches and eight tenths above the stagnant mercury in the upper vessel; because, as it is near fourteen times specifically heavier than water, it will be lifted up by the pressure of the air but the fourteenth part that water is lifted.

To prove further, that a different pressure against the orifices of the unequal legs of a siphon, is the cause of a liquor running through that instrument from a higher into a lower vessel, we may make use of any other fluid, lighter than the fluid to be brought over, instead of air, and leave the bend of the siphon open to the air, as in the following experiment: A B C D (fig. 4.) is a pretty large glass jar with a little water, tinged red to make the experiment the more conspicuous, in its bottom, to the height of an inch, as at E F. On a stand between F and G in the great jar, there is placed a little jar, G H K I, almost full of the said red water; let down the siphon S L M G, open at S, M, and G, into the vessel, so that the end S of the long leg stands in the water at the bottom of the great jar; and G, the end of the short leg in the little jar, at the bottom of its water; pour in oil of turpentine into the great jar up to L, so that the water in the little jar may also be covered with it, and the water will first rise up in both legs of the siphon, so as to meet at the bend L, then it will run out of the little jar into the great one through the siphon, in the direction G H L S, as long as there is any water in the little jar above G.

Instead of hanging a siphon over the side of a vessel, it may be adapted to a cup; so that the short leg being in the cup, the long leg may go down through the bottom of the cup; and then it is called Tantalus's cup.

There are some siphons through which the water will run out of a vessel without sucking the air from them, or

making them in the manner of a waste pipe: but these must be made of capillary tubes whose bore must not be bigger than one tenth of an inch; and as soon as they are put into a vessel of water T S (fig. 5.) they will begin to run, and so continue as long as there is any water above the driving leg. This happens because the attraction of cohesion, which makes water rise up in small tubes, draws the surface V to W in the siphon; where being lower than the surface of the water in the vessel, it must run down; because the column of water W S, is longer or higher than the column S V; and the air pushing down at V, must overcome the resistance of the air pushing upwards at S. For the same reason, a piece of list of cloth, A D, will make the water come out of the vessel and fall down in drops at E; as this piece of cloth is in effect a bundle of capillary siphons made by its interstices. But if the surface of the water in the vessel was at $g h$, the siphon being put in the water, would not run out, but only rise in the siphon up to $e f$, the height to which a tube of that bore would raise the water by the attraction of cohesion. Whenever the vessel is full, this experiment will succeed in vacuo.

SIRE, a title of honour in France, now given to the king only, as a mark of sovereignty. In all placets and petitions, epistles, discourses, &c. to the king, he is addressed under the title of sire.

SIRE was anciently used in the same sense with *sieur* and *seigneur*, and applied to barons, gentlemen, and citizens.

SIREN, *Σειρήν*, in antiquity, a mermaid; a name given to a kind of fabulous beings, represented by Ovid, &c. as sea monsters with womens faces and fishes tails; and by others decked with a plumage of various colours. They are supposed to have been the three daughters of the river Achelous, and called Parthenope, Ligea, and Leucosia. Homer only makes mention of two Sirens, but others reckon five. Virgil places them on rocks, where vessels are in danger of splitting. Pliny makes them inhabit the promontory in Sicily, near cape Pelorus: Claudian says, they inhabited harmonious rocks; that they were charming monsters; and that sailors were wrecked on their rocks without regret, and even expired in rapture. Artedi supposes it to constitute a peculiar genus of cetaceous fishes. The character he gives of it are the following: it has no pinnated tail; the head, neck, and breast, down to the navel, represent those of the human species; there are only two fins on the whole body, and those stand on the breast. Bartholine, in his History of Curiosities, describes such a fish as this, under the name of Syrene, and Barchewitz under the name of *homo marinus*. This author says that he saw one at sea, and that it is wholly different from the manati, and from all other fishes. The Philosophical Transactions also contain an account of a sea-man seen in the American seas, and several other writers of credit give countenance to the story. Their description tells us, that from the navel to the tail it is one shapeless mass of flesh, without any appearance of a finny tail, or any other part of the structure of a fish. The pectoral fins resemble hands, and are composed of five bones, or fingers, joined by a membrane. With these it swims. It were much to be wished, that some accurate ichthyologist might have an opportunity of seeing and examining this creature, if it really exists different from the other animals of the sea. Artedi seems to doubt the truth of the accounts, but thinks it better not to judge of a thing not yet seen, than to pronounce any thing rashly against the accounts of creditable authors.

SIRIUS, in astronomy, the dog-star; a very bright star, of the first magnitude, in the mouth of the constellation canis major, or the great dog.

SISON, corn-parsley, or bishop's-weed, in botany, a genus of plants, the general corolla of which is uniform: the partial corolla is formed of five equal lanceolated inflex petals: there is no pericarpium: the naked fruit is oval, striated, and separable into two parts: the seeds are two, oval, convex, striated on one side, and plane and smooth on the other. The seed of this plant is one of the four lesser hot seeds of the shops, and is an attenuant, aperient, and carminative. It is prescribed in flatulencies

R r

and

and colics, and against obstructions of the menses; and is said also to be a lithontriptic.

SISTRUM, or **CISTRUM**, a kind of antient musical instrument, used by the priests of Isis and Osiris. It is described by Spon as of an oval form, in manner of a racket, with three sticks traversing it breadth-wise, which playing freely by the agitation of the whole instrument, yielded a kind of sound which to them seemed melodious. Mr. Malcolm takes the sistrum to be no better than a kind of rattle. Oisellus observes, that the sistrum is found represented on several medals and on talismans.

SISYMBRIUM, water-creffes, in botany, a genus of plants, the corolla whereof consists of four cruciform, oblong, erecto-patent petals, oftentimes less than the cup, with a great number of unguis: the fruit is a long, crooked, cylindrical pod, consisting of two valves, and containing two cells: the seeds are numerous and small.

The young leaves of this plant are frequently eaten in spring as a sallad: the whole plant is of an acid taste, and is a powerful attenuant and resolvent. It is recommended as a kind of specific in the scurvy, and is eaten in large quantities for that intention with great success. It is good against obstructions of the viscera, and consequently in jaundices, and many of the chronic diseases. It is also a powerful diuretic, and promoter of the menses: the best way of using it is in manner of a sallad, or by drinking the expressed juice, which is at present much a custom with us in spring with that of brook-lime, &c.

SITE, or **SCITE**, *Scitus*, denotes the situation of a house, messuage, &c. and sometimes the ground-plot, or spot of earth it stands on.

In logic, *situs* is one of the predicaments declaring a subject to be so and so placed: and in geometry and algebra, it denotes the situation of lines, surfaces, &c.

SITOPHYLAX, in Grecian antiquity, an Athenian magistrate who had the superintendence of the corn, and was to take care that nobody bought more than was necessary for the provision of his family.

The word is formed from the Greek, *σιτος*, corn, and *φυλαξ*, keeper.

SIUM, water-parsnip, skirret, and ninzin, in botany, a genus of plants, the general corolla of which is uniform: the partial one consists of five inflex equal petals: the fruit is naked, and of an oval or roundish figure, small, striated, and separable into two parts: the seeds are two, roundish, striated, and convex on the one side, and plane on the other.

The leaves of this plant, eaten either crude or boiled, are said to break and expel the stone; to excite urine and the menses; to promote the expulsion of the foetus; and to be good in a dysentery.

SIXAIN, **SIXTH**, *sexagena*, in war, an ancient order of battle, wherein six battalions being ranged in one line, the second and fifth were made to advance, to form the van-guard; the first and sixth to retire, to form the rear-guard; the third and fourth remaining on the spot, to form the corps, or body, of the battle.

The word is French, where it signifies the same thing.

SIXTH, *Sexta*, in music, one of the simple original concords, or harmonical intervals.

The sixth is of two kinds, greater and less, and therefore is esteemed one of the imperfect concords, though each of them arise from a different division of the octave: the greater sixth is a concord resulting from the mixture of the sounds of two strings, that are to each other as 3:5: the less from those of two strings, in the ratio of 5:8.

The less sixth is composed diatonically of six degrees, whence its name, and five intervals, three of which are tones, and two semi-tones; chromatically of eight semi-tones, five of which are greater, and three less: it has its form, or origin, from the *ratio super tri-partiens quinta*.

The greater sixth is diatonically composed like the other, of six degrees and five intervals, among which four are tones, and one semi-tone; chromatically, of nine semi-tones, five of which are greater and four less; consequently, it hath a less semi-tone more than the for-

mer. It has its origin from the *ratio super bi-partiens terttia*.

Anciently the sixth had only one duplicate, which was the thirteenth; but in the modern system of music it has the twentieth for its triplicate, the twenty-seventh for its quadruplicate, &c. every one of which are indifferently marked in thorough base by the figure 6. And even the sixth itself both greater and less, when natural, is not expressed any otherwise, than by a simple 6: but when it is greater or less, by accident, the characters of sharp or flat are set along with the 6.

Besides these two kinds of sixths, which are both good concords, there are two others that are vicious and dissonant; the first, called the defective sixth, composed of two tones and three semi-tones, or of seven semi-tones, five of which are greater, and two less; the second is the redundant sixth, composed of four tones, a greater semi-tone, and a less; whence some call it pentatonon, as comprehending five tones. These two, being both dissonant, should never be used in melody, and very rarely in harmony.

As to the two consonant sixths, they were anciently used very sparingly: at present they are allowed to be used as often as one pleases, as is the case with thirds: the sixths being in reality no other than inverted thirds: but care is usually taken that the first sixth that occurs be a less, the last a greater; and from the greater we rise to the octave; and from the less, fall to the fifth.

SIZE, the name of an instrument used to find the bigness of fine round pearls withal. It consists of thin pieces or leaves, about two inches long and half an inch broad, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second, for pearls from eight grains, or two carats, to five carats, &c. and those of the third, for pearls from six carats and a half to eight carats and a half.

SIZE is also a sort of paint, varnish, or glue, used by painters, &c.

The shreds and parings of leather, parchment, or vellum, being boiled in water and strained, make size. This substance is used in many trades. Mr. Boyle mentions, among other uses, that fine red stands and hanging shelves are coloured with ground vermilion tempered with size, and when dry are laid over with common varnish. There is also a size made of ising-glass, in the same manner, and for the like purposes; but this size will not keep above three or four days, so that no more should be made of it at once than present occasion requires.

The manner of using size is to melt some of it over a gentle fire, and scraping as much whiting into it as may only colour it, let them be well incorporated together; after which you may whiten frames, &c. with it. After it dries, melt the size again, and put more whiting, and whiten the frames, &c. seven or eight times, letting it dry between each time: but before it is quite dry, between each washing, you must smooth and wet it over with a clean brush-pencil in fair water.

To make gold-size take gum animi and asphaltum, of each one ounce; minium, litharge of gold, and umber, of each half an ounce; reduce all into a very fine powder, and add to them four ounces of linseed-oil, and eight ounces of drying-oil; digest them over a gentle fire that does not flame, so that the mixture may only simmer, but not boil; for fear it should run over and set the house a-fire, keep it constantly stirring with a stick till all the ingredients are dissolved and incorporated, and do not leave off stirring it till it becomes thick and ropy; and being boiled enough, let it stand till it is almost cold, and then strain it through a coarse linnen-cloth and keep it for use.

To prepare it for working, put what quantity you may have occasion to use in a horse-muscle shell, adding so much oil of turpentine as will dissolve it, and making it as thin as the bottom of your seed-lac varnish; hold it over a candle, and then strain it through a linnen-rag into another shell; add to these so much vermilion as will make it of a darkish-red: if it is too thick for drawing,

drawing, you may thin it with some oil of turpentine: The chief use of this size is for laying on metals.

The best gold-size for burnishing is made as follows: take fine bole, what quantity you please, grind it finely on a marble, then scrape into it a little beef-suet: grind all well together; after which mix a small proportion of parchment-size with a double proportion of water, and it is done.

To make silver-size: take tobacco pipe clay, in fine powder, into which scrape some black lead and a little Genoa-soap, and grind them all together with parchment-size, as already directed.

SKELETON, σκελετον, in anatomy, an assemblage or arrangement of all the bones of a dead animal, dried, cleansed, and disposed in their natural situation, and kept in that order by means of wires, &c.

The skeleton of the human body being of great use in learning its osteology, we have given a figure of it in plate CXX. where *fig. 1.* represents part of the os frontis covered with its periosteum, the arteries of which are injected. A, the branches which come from the orbit; the other small trunks of the arteries to be observed in several places, are sent from the common teguments to the periosteum.

Fig. 2. The parietal bone of the human foetus, to shew the radiated fibres of a flat bone proceeding from the first ossified point A.

Fig. 3. The thigh-bone of a human foetus, to shew the parallel fibres of a cylindrical bone. A, the part which first ossifies. B B, the two extremities in a cartilaginous state.

Fig. 4. A, A, A, A, the plates of the thigh-bone separated. B, B, the cancelli.

Fig. 5. The transverse section of a bone burnt till it is white, to shew the longitudinal canals of the bones.

Fig. 6. Marrow viewed with a microscope.

Fig. 7. The thigh-bone sawed longitudinally through the middle. B, B, the union of the bone with its epiphyses.

Fig. 8. The os ilium sawed through the middle.

Note, by comparing *fig. 7* and *8*, the different internal structure of round and broad bones is seen.

Fig. 9. A, the head of the thigh-bone of a child. B, the round ligament connecting it to the acetabulum. C, the circular ligament with its arteries injected. D, the numerous vessels of the mucilaginous gland injected.

Fig. 10. The skeleton of a man. A, the frontal bone; B, the parietal bone; C, the temporal bone; D, the occipital bone; E, the bones of the nose; F, the os malarum; G, the superior maxillary bone; H, the lower jaw; I, the teeth; K, the seven vertebræ of the neck, with their cartilages between them; L, L, L, &c. the twelve vertebræ of the back; M, the five vertebræ of the loins; N, the cartilages between the vertebræ of the loins; O, the os sacrum; P, the os coccygis; Q, the os ilium; R, the os pubis; S, the os ischium; T, the seven true ribs; U, the five false ribs; V, the sternum; X, the clavicles; Y, the scapula; Z, the humerus, or arm-bone; a, the ulna; b, the radius; c, the carpus; d, the metacarpus; e, the phalanges digitorum; f, the thigh-bone; g, the rotula; h, the tibia; i, the fibula; k, the tarsus; l, the metatarsus; m, the phalanges of the toes; n, the head of the radius; o, the head of the ulna; p, the bones of the carpus; q, the lower appendix, which receives the head of the radius; r, the lower appendix, which receives the head of the ulna; s, the upper head of the os femoris, which is received into the acetabulum or coxendix; g, the outer trochanter; i, the trochanter minor; k, l, the two lower heads of the thigh-bone; p, the head of the tibia.

Fig. 11. A view of the lower part and side next the nose of the left os maxillare, with the palate-bone, and os turbinatum inferius. γ, the nasal process. δ, the great tuber. ε, the palate-plate. ζ, the nasal spine. η, the orifice of the antrum maxillare. x, the os spongiosum or turbinatum inferius. λ, the two dentes incisores. μ, the caninus. ν, the five dentes molares.

Fig. 12. The palate-bone. A, the superior side of its palate-plate. B, its posterior edge. C, the anterior edge. D, the nasal spine; i, the nasal plate. H, the

ridge on which the os spongiosum inferius rests. E, the process applied to the sphenoid bone. F, the orbiter process.

Fig. 13. A view of the surface next to the mouth of the right side of the lower jaw; 1, the substance in the middle of the chin; 2, the base of the jaw; 3, the angle; 4, the corone; 5, the condyle; 6, the rough print of the internal pterygoid muscle; 7, the entry of the channel for the nerve and blood vessels; 8, the five grinders.

Fig. 14. A tooth cut perpendicularly, viewed with a microscope; A, the fibres of the cortical part; B, the bony part; C, the entry at the point of the root to D, the channel for the nerve and blood vessels.

Fig. 15. The internal side of the right temporal bone. b, the edge which forms the squamous suture. c, the prints of the convolutions of the brain. d, the mammary part. e, the ridge of the os petrosum. f, the internal auditory hole. g, the extremity of the os petrosum, where the internal carotid artery enters the skull.

Fig. 16. An internal view of the sphenoid bone. 1, 1, the wings. 2, 2, the transverse spinous processes. 3, 3, the anterior clinoid processes. 4, the posterior clinoid process. 5, the print of the conjoined optic nerves. 6, the sella turcica. 7, the posterior part, which joins the occipital bone. 8, 8, the holes for the optic nerves. 9, 9, the foramina lacera. 10, 10, the round holes for the second branch of the fifth pair of nerves. 11, 11, the oval holes for the third branch of that pair of nerves. 12, the holes for the arteries of the dura mater. 14, the internal pterygoid process. 15, the external pterygoid process.

Fig. 17. An exterior view of the ethmoid bone. E, the cristagalli. F, the nasal plate. G, the right superior os turbinatum. H, the right os planum. L, the posterior part which is joined to the sphenoid bone.

Fig. 18. A posterior view of the two nasal bones. A, their superior sides. B, their exterior sides. C, their inferior sides.

Fig. 19. The side of the os unguis next the nose. A, the orbiter part. B, the lacrymal part. C, the furrow between those two convex parts.

Fig. 20. A posterior view of the left os malarum. A, the orbiter process. B, the inferior orbiter process. C, the malar process. D, the zygomatic process. E, the internal orbiter process. F, the hollow made by the temporal muscle.

SKIN, Cutis, in anatomy. See the article CUTIS.

SKIN, in commerce, is particularly used for the membrane stripped off the animal to be prepared by the tanner, skinner, currier, parchment maker, &c. and converted into leather, &c.

Skins and the hair of beasts manufactured become parchment and vellum; leather, of which are made shoes and boots, saddles, harnesses, and furniture for horses, gloves and garments, coaches and chairs, household-stuff, covers of books, drinking vessels, &c. and furs for cloathing, hats, caps, &c. Those branches of trade that are derivable from the skin-trade, render it a very great mercantile concern, and well deserving preservation as much as we can within ourselves. The English have greatly increased their quantity of furs and skins of all sorts from their northern colonies, since they planted northward towards Nova-Scotia, Annapolis, and other places towards the river Canada.

The several sorts of skins brought to Europe from those parts are the following kinds, viz. deer-skins, bear, beaver, otter, racoon, fox, elk, cat, wolf, martin, mink, musqueth, fisher, &c.

The Indians in Carolina and Virginia dress buck and doe skins in this manner: the felt being taken off, they strain them with lines, or otherwise, much like the clothiers racks, in order only to dry them. When the hunting time is over, the women dress the skins, by putting them in a pond, or hole of water, to soak them well; then with an old knife, fixed in a cleft stick, they force off the hair, whilst they remain wet. This done, they put them into a kettle, or earthen-pot, and a proportion of deer's brains, dried and preserved for this purpose, is put in along with them; this vessel is set on the fire till they are more than blood-warm, which will

make

make them lather and scour clean; after this, with small sticks, they wrest and twist each skin as long as they find any wet to drop from them, letting them remain so wrested for some hours; and then they untwist and stretch each of them in a sort of a rack, so that every part is extended: and, as the skin dries, they take a dull hatchet, or some such instrument, and rub them well over, to force all the water and grease out of them, till they become perfectly dry, and then their work is done.

In this manner one woman, for the men never employ themselves in this work, will dress eight or ten skins in a day, that is, begin and finish them.

SKINNER, one who works and deals in skins.

SKIRMISH, in the art of war, a disorderly kind of combat, or encounter, in presence of two armies, between small parties, or persons, who advance from the body for that purpose, and introduce to a general and regular fight.

SKULL, *Cranium et Calvaria*, in anatomy, that part of the head which forms its great bony cavity; and in a living subject contains the brain.

The shape of the skull is oval: its exterior surface is convex: and its interior, concave; its round figure is an advantage to its capacity: it is a little depressed and longish, advancing out behind and flatted on the two sides that form the temples, which contributes to the enlargement of the sight and hearing: it is of unequal thickness in the several parts, and is composed of two lamellæ, or tables, an exterior and interior, laid or applied over each other, between which there is a diploë, or medullium, being a thin spongy substance, made of bony fibres detached from each lamina, and full of little cells of different bignesses: the tables are hard and solid, the fibres being close to one another: the diploë is soft, in regard the bony fibres are here at a greater distance; a contrivance whereby the skull is not only made lighter, but less liable to fractures; the external lamina is smooth, and covered with the pericranium: the internal is likewise smooth, abating the furrows made by the pulsation of the arteries of the dura mater before the cranium be arrived at its consistence: it has several holes, thro' which it gives passage to the spinal marrow, nerves, arteries, and veins, for the conveyance and reconveyance of the blood, &c. between the heart and the brain.

The bones of the skull are eight, viz. the os frontis, the two parietal bones, the two bones of the temples, the occipital, the sphenoides, and the ethmoides; each of which are described under their several names.

All the bones of the cranium are found to be imperfect in new-born infants: the sinus and its medullium are almost wholly wanting; the bony fibres in the formation of almost all of them, are carried in form of rays from a center towards the circumference; and most of them are not single, as in adults, but composed each of several frustules, or little pieces; nor are the sutures at that time formed, and frequently there are triquetrous little bones between them.

In adults the several bones of the skull are in general joined by sutures: these sutures are either common or proper; the proper sutures are distinguished into the true and the false or spurious; they are called true sutures when the bones are joined together by means of a multitude of unequal denticulated eminences, forming an appearance somewhat like the edge of a saw: these denticulations enter mutually into each other's sinuses, and on the outside are most plainly visible: of this kind are those called the coronal, sagittal, and lambdoidal sutures.

The false or spurious sutures are those squamose ones of the temporal and parietal bones, and of the os frontis and sphenoides, in the angle where they unite with the parietal ones. The common sutures are the transversal one, which joins the os frontis with the bones below it, the sphenoidal, the ethmoidal, and the zygomatic; but these are of little moment. Some authors mention the having met with skulls in which there were no sutures at all. Between the sutures, particularly the lambdoidal and sagittal, there are found, in many skulls, certain small bones; these are called, by some, ossa triquetra, from their figure; by others, ossa wormiana: they are uncertain in their figures and situation, and are

joined to the others by futures: these bones are by some esteemed a great medicine in epilepsies.

The use of the sutures is, 1. That the dura mater may in those parts be very firmly joined to the cranium and pericranium. 2. That, in infants, the head may the more easily be extended in its growth from the several bones being at that period disunited at these places. 3. That the transpiration from the brain may be the more free and easy at that time of life in which they are open, and at which also the habit is more humid. 4. That very large fractures of the skull might in some measure be prevented: and finally, there is another advantage in their openness in children; namely, that medicinal applications to the external part of the head may penetrate and do service.

The foramina in the cranium are numerous, and their uses important: these are divided into the external and internal: by the external are meant those which are easily discovered on the external surface of the skull; and by the internal are meant those which are most obvious in the internal surface. Of the larger internal foramina we count eleven pair, affording passage to the arteries, veins, and nerves of the brain; besides these, we are to remark one which is single, namely, the great foramen of the occipital bone, that gives passage to the medulla spinalis, and with it to the accessory spinal nerves, and to the vertebral arteries. Particular regard is to be had to the first pair of these foramina, which may indeed be more properly called a congeries of the foramina of the os cribrosum; these give passage to the filaments of the first pair of nerves, called the olfactory nerves: the second pair are in the sphenoidal bones, and give passage to the optic nerves: the third pair are called the unequal and lacerated foramina, and give passage to the third and fourth pair of the nerves, to the first branch of the fifth pair, and to the sixth pair; as also to the emissary of the receptacles of the dura mater: the fourth pair are in the sphenoidal bone, and give passage to the second branch of the fifth pair of nerves, which is distributed to the several parts of the upper jaw: the fifth, or oval foramina, give passage to the third branch of the fifth pair, and to the emissary of the dura mater: the sixth is a very small foramen, and admits of an artery, which is distributed over the dura mater, and is that which forms the impressions of little shrubs or trees on the parietal bones: the seventh is placed between the sella equina and the petrose apophysis, and it transmits no vessels, but is shut up by the dura mater: the eighth pair of foramina give passage to the carotid arteries, whence it is called the carotid foramen; and the intercostal nerve has its egress also at this opening: through the ninth, which is in the os petrosum, passes the auditory nerve: through the tenth, which is between the os petrosum and the occipital bone, pass the par vagum and the lateral sinuses of the dura mater, together with the spinal nerve: the eleventh is in the os occipitis, near the edge of the foramen magnum; and through this pass the ninth pair of nerves, called the lingual.

Besides these foramina, there are a number of little ones in the os petrosum, often very visible; one of these carries back a branch of the auditory nerve to the dura mater; and the other principal one transmits the sanguiferous vessels to the labyrinth, or the internal organ of hearing. See the article EAR.

Of the external foramina, there are two proper ones of the os frontis, a little above the orbits; these are, from their situation, called supra orbitalia: they give passage to the ophthalmic nerve of Willis. Besides these, there are four other foramina common to the os frontis, and to the plane or papyraceous bones of the orbit; two of these are placed on each side, and they transmit little nerves and vessels to the sinus of the ethmoidal bone. In the parietal bone there is one, which serves for the passage of a vein from the cutis of the cranium into the sagittal sinus of the dura mater, or from the sagittal sinus to the external veins of the head; but this is often wanting. In each of the ossa temporum there are three common foramina; the first of these is the foramen jugale, which serves for the passage of the crotophite-muscle; the second is large, in which is the sinus of the jugular vein; and the third is the ductus Eustachii, situated be-

tween

tween the petrosus and the sphenoides, and leading from the mouth into the internal ear. Besides these common foramina of the ossa temporum, there are also three proper ones: 1. The meatus auditorius. 2. The aquæduct of Fallopius, situated between the mastoide and styloide process, and transmitting the hard portion of the auditory nerve. 3. A foramen behind the mastoide process, serving for the ingress of a vein into the lateral sinus, or for the egress of one from the lateral sinus into the veins of the occiput. In the occipital bone there are two foramina, situated behind the condyloide apophyses, and serving to give passage to the vertebral veins, into the lateral sinuses of the dura mater: these, however, are wanting in many skulls. In the sphenoides, besides the internal ones already described, are the apertures of the sinuses into the nostrils, common to them with the bones of the palate, and which are the apertures of the nares and fauces: there is another canal in the upper part of the pterygoide processes, serving for the passage of the novum emissarium of the dura mater. In the os ethmoides there are, 1. Those common to this bone with the os frontis, situated in the interior side of the orbit, and already described. And, 2. The apertures of the ethmoidal sinuses into the nostrils. In the examination of different skulls, other foramina, besides these, will occasionally be found in different places; but these are either extraordinary and *lusus naturæ*, as is often the case; or they are otherwise such as serve only to give passage to vessels serving for the nutrition of the bones in which they stand.

Concealed Injuries and Wounds of the SKULL. When a blunt instrument is the occasion of any injury of the cranium, if the injured part does not sufficiently appear of itself, great industry is necessary to discover it. Where the common integuments appear tumid and soft, they are in this case to be divided to the bone; but in making the incision, care must be taken not to lay too much stress upon the knife, lest splinters of the fractured cranium should, by that means, be forced upon the brain. The best way to make this incision, according to Heister, is in form of the letter X, and about an inch and half in length, lifting up the skin at each angle, and leaving the bone bare. The blood that is spilt, may be taken up by a sponge, and dry lint stuffed between the skin and the cranium: and having thus found out the injured part of the cranium, the trepan is to be applied, if it be found necessary. If splinters of the bone are now found, they must be removed either with the fingers or forceps, or, when they hang to the pericranium, with scissars; but when they adhere pretty firmly to the neighbouring parts of the cranium, it is more advisable to replace them, than to endeavour to remove them by violence.

In wounds of the cranium, or skull, the first business is to find whether they are terminated in the external parts of the cranium, or whether they penetrate into its cavity: this is to be known, 1. By the eye. 2. By the probe; which, however, must be gently used here, for fear of bringing on farther mischief. 3. By examining the instrument with which the blow was given, and considering the degree of force with which it was impelled. And, lastly, the presence or absence of very bad symptoms: for a violent blow upon the head will always be attended with vomitings and vertigos, and blood will be discharged from the nose, ears, and mouth, and the wounded person will lose his speech and senses. These disorders will appear, sometimes sooner and sometimes later, but are always most violent, when the wound is by a fall, or by some blunt instrument; in which cases the cranium is usually much shattered. The blood which discharges itself by the wound, that is made by a sharp instrument, will insinuate itself between the common integuments and the cranium: in the contusions that are made with blunt instruments, sometimes it will be concealed under the cranium; and, by corrupting the periosteum and the cranium, will bring on ulcers and caries of the bone, and frequently occasions fevers, convulsions, and death.

SKY, the blue expanse of air, or atmosphere.

Sir Isaac Newton attributes the azure colour of the sky to vapours beginning to condense therein, which have attained consistence enough to reflect the most reflexible

rays, viz. the violet ones; but not enough to reflect any of the less reflexible ones. M. de la Hire attributes it to our viewing a black object, viz. the dark regions beyond the limits of the atmosphere, through a white or lucid one, viz. the air illuminated by the sun: a mixture of black and white always appearing blue. But this conjecture is not originally his, being as old as Leonardo da Vinci.

SKY-COLOUR. To give this colour to glass, set in the furnace a pot of pure metal of frit from rochetta, or barilla, but the rochetta frit does best; as soon as the metal is well purified take for a pot of twenty pounds of metal six ounces of brass calcined by itself; put it by degrees, at two or three times, into the metal, stirring and mixing it well every time, and diligently scumming the metal with a ladle: at the end of two hours the whole will be well mixed, and a proof may be taken; if the colour be found right, let the whole stand twenty-four hours longer in the furnace, and it will then be fit to work, and will prove of a most beautiful sky-colour.

SLAB, an outside sappy plank or board sawed off from the sides of a timber-tree: the word is also used for a flat-piece of marble.

SLABS of Tin, the lesser masses, which the workers at the tin mines cast the metal into: these are run into moulds made of stone.

SLACKEN, in metallurgy, a term used by the miners to express a spongy and semi-vitrified substance, which they use to mix with the ores of metals, to prevent their fusion. It is the scoræ or scum, separated from the surface of the former fusions of metals. To this they frequently add lime-stone, and sometimes a kind of coarse iron-ore, in the running of the poorer golden ores.

SLATE, a bluish fossil stone, very soft when dug out of the quarry, and therefore easily cut or sawed into thin long squares, to serve instead of tiles for the covering of houses; also for making tables, &c.

The ancients were unacquainted with the use of slate, instead of which they covered their houses with shingles, as we read in Pliny. Besides the blue slate we have also in England a greyish slate, called also Horsham stone, from a town in Sussex of that name, where the greatest quantities of it are found.

The blue slate is very light and lasting, but chargeable withal, because the roof must be first boarded over, the slates hung with tacks, and laid with finer mortar than tiles. The grey slate is chiefly used in covering churches, chancels, &c.

SLAVE, a person in the absolute power of a master; either by war or conquest.

Menage and Vossius derive the word from *Sclavus*, the name of a Scythian people, whom Charlemagne condemned to perpetual imprisonment; whence the Italians formed their *schlavo*, the Germans their *schlave*, the French their *esclave*, and we *slaves*.

SLAUGHTER. See the articles **MAN-SLAUGHTER**, **HOMICIDE**, &c.

SLAUGHTER-SKINS, a term used by our curriers and leather-dressers for the skins of oxen, or other beasts, when fresh, and covered with the hair: such as they receive them from the slaughter-houses, where the butchers flay the carcase.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, &c.

This is also the name of a large smith's hammer, to be used with both hands. Of this there are two sorts; the uphand-sledge, which is used by under-workmen, when the work is not of the larger sort; it is used with both the hands before, and they seldom raise it higher than their head; but the other, which is called the about-sledge, and which is used for battering or drawing out the largest work, is held by the handle with both hands, and swung round over their heads at their arm's end, to strike as hard a blow as they can.

SLEEP, that state wherein the body appearing perfectly at rest, external objects move the organs of sense as usual, without exciting the usual sensations.

Every one knows that in sleep there is a cessation from action. When waking, we walk, discourse, move this or that limb, &c. but, in natural and undisturbed rest, there is nothing of all these; that is, whereas, being awake,

awake, we perform several motions by the voluntary contraction of our muscles; when asleep, those muscles only are contracted, whose action is, in a manner, involuntary, or to which the mind has always so constantly determined the spirit, that it does it by a habit, without the intervention of the reasoning faculty; such are those of the heart and breast. So that there is, at this time, a relaxation or looseness of the moving fibres of the several members, or, at least, such a quiet position and state of them, by which all the antagonist muscles are in an æquilibrium and equality of action, not overpowering one another. For this, indeed, seems to be one great design of sleep, to recover to the parts overstretched with labour their former tone and force; and, therefore, we do naturally, when composing ourselves to rest, put our body into that posture which most favours the particular wearied limbs, and conduce to this end.

In the next place, it is very plain that there is in sleep, not only a rest and suspension from acting of most of our bodily organs, but even of our thinking faculty too; that is, to prevent cavils, a ceasing from such thoughts as when waking we are exercised about, which we do reflect upon, and will, to employ our mind with: for, though dreams are thoughts, yet they are but imperfect and incoherent ones, and are, indeed, either so faint and languid representations, as to be consistent with our sleep, as some may be; or else, if they be strong and lively, they are, as every one knows, the interruption and disturbance of it.

From hence it will follow, that the motion of the arterial fluid must be, *cæteris paribus*, more sedate, even, and regular in the time of sleeping, than waking; for, besides the various alterations which, in the latter state, this receives from the several passions of the mind, the very contractions of the muscles themselves, in exercises of the body, do differently forward its course; whereas, in sleep, the force of the heat and pectoral muscles, being more constant and uniform, gives it a more calm and equally continued impulse.

Hence, also, it will come to pass, that the influx of the liquor of the nerves into the organs of the body, as also its reflux towards the brain, is, in sleep, either none, or very inconsiderable; that is, that this fluid has, at this time, but little or no motion: for it is muscular action and sensation that require it to be thus determined, this way or that, which are now hardly any: and yet, by the arrival of the blood at the brain, this juice will still be separated there, fit to be derived into its canals or tubes: so that, by this means, there will be a kind of accumulation, or laying up in store of spirits for the offices and requirements of waking.

Thus we may, in short, look upon this time as the time of wearing out, or the destruction of the animal fabric; and the time of sleep, as that in which it is repaired and recruited; and not only on the account we have just mentioned concerning the nervous liquor, but also with respect to all the other parts, as well fluid as solid; for action does necessarily, by degrees, impair the springs and organs; and in motion something is continually abraded and struck off from the distractile fibres, which cannot be otherwise restored, than by their being at rest from tension. Besides that, such a regular and steady course of the blood as we have observed to be in sleep, is by far more fit and proper for nutrition, or an apposition of parts to the vessels, which an uneven hurry of it is more apt to tear off and wash away.

SLEEPER, or the **GREAT SLEEPER**, in zoology, the hairy-tailed mus with red feet.

This animal is of the size of the rat, but more corpulent; the head is short and thick; the opening of the mouth small; the nostrils flesh-coloured; the eyes large, black, and prominent; and the ears large and naked. It is frequent in many parts of Europe, and retires in winter into caverns under the ground, where it carries however a considerable store of nuts and other fruits.

SLEEPERS, in natural history, a name given to some animals which sleep all the winter: such are bears, marmotes, dormice, bats, hedge-hogs, swallows, &c. These do not feed in winter; have no sensible evacuations, breathe little, or not at all, and most of the viscera cease

from their functions. Some of these creatures seem to be dead, and others to return to a state like unto that of the foetus before birth. In this condition they continue, till by length of time maturing the process, or by new heat, the fluids are attenuated, the solids stimulated, and the functions begin where they left off.

SLEEPERS, in the glass trade, are the large iron bars crossing the smaller ones, and hindering the passage of the coals, but leaving room for the ashes.

SLICH, in metallurgy, the ore of any metal, particularly of gold, when it has been pounded, and prepared for farther working.

SLIDING, in mechanics, is when the same point of a body, moving along a surface, describes a line on that surface.

SLIDING Rule. See **RULE**.

SLING, *Funda*, an instrument serving for casting stones with great violence. The inhabitants of the Balearic islands were famous in antiquity, for the dexterous management of the sling: it is said they bore three kinds of slings, some longer, others shorter, which they used according as their enemies were either nearer or more remote. It is added, that the first served them for a head-band, the second for a girdle, and that the third they constantly carried with them in the hand.

SLIPPING, among gardeners, the pulling off a sprig from a branch, or a branch from an arm of the tree. And so a slip may have its rinds double and treble slipped, or its stalks ragged.

SLITTING MILL. See the article **SMITHERY**.

SLOATH, or **SLOTH**, in natural history, an animal remarkable for its slow motion.

The face of this creature is covered with hair; the claws are of a subulated form; there are no ears, nor are there any middle teeth. This is a very extraordinary animal, both in figure and qualities. It is hard to say to what other it is equal in size, since it is like none in shape; the length of the body is about a foot, and when well fed its thickness is equal to its length; the feet are flatted or plain, in the manner of those of the bear or monkey, but are extremely narrow; the claws are very long and sharp; the head is small and round; and the face something resembling that of the monkey; the colour of the whole animal is a pale greyish brown. This creature is so very tedious in all its motions, that it will be three or four days in climbing up and coming down a tree, and does not go the length of fifty paces upon even ground in a day.

SLOUGH, a deep muddy place. The cast skin of a snake, the damp of a coal-pit, and the scar of a wound, are also called by the same appellation. The slough of a wild boar is the bed, or mire, wherein he wallows, or in which he lies in the day time.

SLOUTH, or **SLOUGHT**, in hunting, is used for a company of some sorts of wild beasts, as a slouth of bears.

SLOW-WORM, in zoology, the English name of the *cæcilia*, called also the blind-worm, and by some the deaf adder: it is very venomous, and its bite often fatal.

SLUDS, a term used by the miners in Cornwall for half-roasted ores.

SLUICE, in hydraulics, a frame of timber, stone, earth, &c. serving to retain and raise the water of the sea, a river, &c. and on occasion to let it pass; such is the sluice of a mill, which stops and collects the water of a rivulet, &c. in order to discharge it at length, in greater plenty, upon the mill-wheel: such also are those used in drains, to discharge water off lands; and such are the sluices of Flanders, &c. which serve to prevent the waters of the sea overflowing the lower lands, except when there is occasion to drown them.

Sometimes there is a canal between two gates or sluices, in artificial navigation, to save the water, and render the passage of boats equally easy and safe, upwards and downwards; as in the sluices of Briare in France, which are a kind of massive walls, built parallel to each other at the distance of twenty or twenty-four feet, closed with strong gates at each end, between which is a kind of canal or chamber, considerably longer than broad, wherein a vessel being inclosed, the water is let out at the first gate, by which the vessel is raised fifteen

teen or sixteen feet, and passed out of this canal into another much higher.

By such means a boat is conveyed out of the Loire into the Seine, though the ground between them rise above one hundred and fifty feet higher than either of those rivers.

Construction of SLUICES. The construction of sluices ought to be conducted by an able engineer, who is well acquainted with the action of fluids in general; and particularly with the situation of the place, the nature of the soil, &c. where the sluice is to be erected: if on the sea-shore, he ought to be perfectly well acquainted with the effects of the sea, on that coast, and the seasons when it is calm or stormy, that he may be able to prevent the fatal accidents thence arising: and, if in a river, it is necessary to know whether it usually overflows its banks, and at what seasons of the year its waters are highest and lowest. The machines for driving the piles should be placed about forty yards from the side of the sluice, above and below it. As to the depth of the sluices, it must be regulated by the uses for which they are designed: thus, if a sluice is to be erected at the entrance of a basin for shipping, its depth must correspond with the draught of water of the largest ship that may, at any time, have occasion to enter thereby. The rule usually observed, is to make the surface of the bottom of the canal on a level with the low-water-mark: but if the bottom of the harbour and canal be such, as to be capable of becoming deeper by the action of the water, Belidor very justly observes, that the bottom of the sluice-work should be made deeper than either.

When a sluice is to be placed at the bottom of an harbour, in order to wash away the filth that may gather in it, by means of the waters of a river or canal; in this case the bottom of the sluice-work should be two feet or eighteen inches higher than the bottom of the harbour, that the water may run with the greater violence.

An engineer ought always to have in his view, that the faults committed in the construction of sluices are almost always irreparable. We shall therefore lay down some rules, from Belidor, for avoiding any oversights of this kind: 1. In order to adjust the level of the sluice-work with the utmost exactness, the engineer ought to determine how much deeper it must be than a fixed point: and this he should mark down in his draught, in the most precise terms possible. 2. When the proper depth is settled, the foundation is next to be examined; and here the engineer cannot be too cautious, lest the apparent goodness of the soil deceive him: if the foundation is judged bad, or insufficient to bear the superstructure, it must be secured by driving piles, or a great work of carpentry. 3. There should be engines enough provided for draining the water; and these should be entirely under the direction of the engineer, who is to take care that they be so placed as not to be an obstacle to the work; and also cause proper trenches to be cut, to convey the water clear off from the foundation. 4. When the sluice is to be built in a place where the workmen will be unavoidably incommoded by the waters of the sea, &c. all the stones for the mason-work, as well as the timbers for that of carpentry, should be prepared beforehand; so that when a proper season offers for beginning the work, there remains nothing to be done, but to fix every thing in its place. 5. In order to shew the state of the work, an exact journal should be kept of the materials employed, to be signed every week by the chief engineer and undertaker; observing to distinguish the different pieces of materials, and the places where they were employed. 6. When an undertaker is found, who is not only able to be at the expence of providing all the materials, but likewise vigilant and active to execute whatever is judged necessary for the perfection of the work, it would be the worst of policy to give the preference to others, who through ignorance, or dishonesty, bring in estimates lower than it is possible to execute the work as it ought. However, that the conditions of the contract may be properly executed, the chief engineer, or other persons of unquestionable understanding and honesty, commissioned for that purpose, should take care that able workmen be employed, and that they execute their several parts in a proper manner.

Sluices are made different ways, according to the uses they are intended for: when they serve for navigation, they are shut with two gates, presenting an angle towards the stream; but when made near the sea, there are two pair of gates, one to keep the water out, and the other to keep it in, as occasion requires: the pair of gates next the sea present an angle that way, and the other pair the contrary way; the space inclosed by these gates is called a chamber.

When sluices are designed to detain the water in some parts of the ditch of a fortress, they are made with shutters to slide up and down in grooves; and when they are made to cause an inundation, they are then shut by means of square timbers let down into cullises, so as to lie close and firm.

Particular care must be taken, in the building of a sluice, to lay the foundation in the securest manner possible; to lay the timber grates and floors in such a manner, that the water cannot penetrate through any part, otherwise it will undermine the work; and, lastly, to make the grates of a proper strength, in order to support the pressure of the water; and yet to use no more timber than is necessary.

As a general construction is much preferable to a particular one, we shall here give the description of a large sluice, with two pair of gates, from Mr. Muller's Fortification; which may be adapted to any particular case, provided a proper allowance be made for the various circumstances in regard to their use and situation, as already observed.

To construct then the plan of a sluice, suppose half its width, OC, (plate CXIX. fig. 6.) to be divided into six equal parts, or the whole breadth into twelve: these parts serve for a scale whereby the dimensions of the several parts of the work are determined. Through the point O, draw the line AB at right angles to OC, and take OB = 30 of the above parts; or, which is the same, equal $2\frac{1}{4}$ the width; through the points A and B, draw the lines AR, BS, at right angles to AB; and let the lines passing thro' the point C, and parallel to AB, meet those last lines in M and Q: then, if MN and PQ be taken each equal to nine parts, and each of the lines MR and QS equal to six, the lines NR and PS will determine the wings of the sluice and NP the body: and if the lines AR, BS, be produced, so that the parts RV and ST be each six parts, they will determine the faces.

The part of the length, OB, exceeds the other part OA, by $\frac{1}{4}$ of the width; because we suppose a turning bridge is to be placed on that side, for a communication from one side of the sluice to the other; but when there is no occasion for such a bridge, OB is made equal to OA; and then the whole length will be but four times and a half the width, which is, Mr. Belidor thinks, the best length for a great sluice.

Next to determine the chamber, and the position of the gates, take OD and OL, each equal to four parts; and draw the lines DG and HL parallel to OC: then if the lines GK and HI be drawn, so as to make the angles DGK and LHI each = $35^{\circ} 16'$, it will be the best position that can be given. The cavities x, y , are a foot each way in large sluices, and but nine inches in middling ones: they serve for letting down square timbers to form a batardeau on each side, in case the gates or floor want to be repaired.

The recesses Ga, Hb, in the wall, are made to receive the gates when open; and are of such a depth, that they may be flush with the wall, and not make that part narrower than the rest of the sluice. The thickness of the wall from N to P is equal to $\frac{1}{4}$ of the depth of water; the parts RN and PS are $\frac{3}{4}$, and at V and T $\frac{2}{3}$. The counter-fort W is determined by producing the lines LH and DG, and projects beyond the wall by $\frac{1}{4}$ of the width of the sluice.

As to the timber-grates under the floor and foundation (fig. 7.) if the foundation be bad, we suppose piles to be driven under the crossings of the sleepers m and the tie-beams n ; and to prevent the water from getting under the foundation, six rows of dove-tail piles are driven, viz. one at each end, one at each of the angles N and P, (fig. 6.) marked p (fig. 7.) and one on each side of the chamber; and it must be observed, that, except-

ing

ing those at the angles N and P, the rest are all driven between two sleepers, in order to keep them tight and close together. The sleepers and tie-beams are partly let into each other, and bolted together. And as to the masonry between the gratings, bricks are preferred to small stones; as being much closer, and filling up every part more exactly: they are laid in terras-mortar, as well as the rest of the foundation; and the whole is covered with a floor of three-inch thick oaken planks, laid lengthwise. This done, the frames made to support the gates at the bottom, are laid in their proper places; which are composed of a cell *r*, two hurters *s*, two braces *v*, and a tong *t*. The cell enters about three feet into the side walls, and the sockets to receive the pivots of the gates are placed in it; the tong ought to be so long, as to cross three sleepers, to which it is strongly fastened; and the cell, tong, and hurters, ought to have the same dimensions, and their height must be such as to be a foot above the last floor of the sluice and chamber; for which reason, the piles under the chamber are left a foot higher than the rest.

Over the first floor is placed another, composed of sleepers and tie-beams, &c. answering exactly to those underneath, and covered with strong oaken planks, laid lengthwise and nailed to the sleepers, as in the first floor. But upon the second floor is laid another of only two inch thick planks, which do not enter the wall, that they may be repaired when needful: this last floor may be made of yellow deal, and its seams must be well caulked, to prevent the water from making its way thro' them.

The walls must be made about three feet higher than the greatest depth of the water; and the faces are formed of the largest stretchers and heads that can be had, laid in terras-mortar, and cramped together: but the rest of the work may be done with good common mortar. The top of the wall must be covered with large flat stones or bricks laid in terras-mortar, to prevent the water from penetrating into the masonry: and when all is finished, a bed of clay should be rammed against the wall, two feet thick, all round the outside; beginning as low as the foundation, and raised as high as the wall.

To prevent the water from carrying off the earth, by its fall at the ends of the sluice, a false floor of fascines is made of as many fathoms long as the water in the sluice is feet high: this false floor is fastened with pickets upon an artificial bed of clay, nearly level with the floor of the sluice; and above the fascines is laid a pavement of hard stones well secured, so that the current may not tear them up. And for the greater security, a row of dove-tail piles is driven at each end: and it ought to be observed, that both floors, viz. that of the sluices, and that above the fascines, must have a gradual descent of about $\frac{1}{8}$ part of the length.

The cross section (*fig. 8.*) shews the position of a row of piles, and the sleepers above them, into which they are tenoned; also the heads of the tie-beams, the floor between them, the cell and the two floors above it: there is also seen a row of dove-tail piles, broken off in the middle, in order to see part of the masonry *aa*, between the piles, and under the sleepers. The out-sides of the gates are also seen in this section; also how the planks are joined in the frame, the shutters, *x, x*, and the irons both of the gate and shutters.

In the construction of gates, particular care should be taken to join the several pieces together, in such a manner, that the whole frame may be as strong as possible, and yet not to make them more heavy than necessary. The principal parts of the frame of a gate are two stiles or uprights; that which is next to the wall, and to which the pivots are fixed, being called the pivot post, and the other the chamfered stile, from being edged off so as to make a plain joint with the other gate. The other pieces, which cannot be seen in this section, consist of several rails, placed not nearer to each other than twenty-four inches, not farther than thirty; and of several braces, which form the same angle with the pivot-post, as the joints of the planks on the outside.

As it would be too tedious to calculate the proper strength of each piece, we shall give their dimensions from Mr. Belidor, which, he says, were taken from

those most approved in practice. Supposing then the pieces of the principal frame to be the same, in the same sluice, they will be as follows, in different sluices. In those from 8 to 12 feet wide, the principal pieces should be 8 inches thick, and 10 broad; the intermediate rails, 6 by 8; the braces and monions, or short uprights to form the wickets, 4 by 6; and the whole covered by two-inch thick planks, as well as all the gates of sluices under 37 feet wide. In sluices from 13 to 18 feet wide, the principal pieces should be 10 by 12 inches; the intermediate rails, 8 by 10; and the braces and monions, 4 by 6. In sluices from 19 to 24 feet wide, the principal pieces should be 12 by 14 inches; the intermediate rails, 12 by 12; and the braces and monions, 5 by 7. In sluices from 25 to 30 feet wide, the principal pieces should be 14 by 16; the intermediate rails, 12 by 13; and the braces and monions 6 by 8. In sluices from 31 to 36 feet wide, the principal pieces should be 15 by 17; the intermediate rails, 13 by 14; and the braces and monions, 7 by 9. In all sluices from 37 to 42 feet wide, the principal pieces should be 16 by 18; the rails 14 by 16; and the braces and monions, 7 by 9. Lastly, in all sluices from 42 to 48 feet wide, the principal pieces should be 18 by 20; the rails, 15 by 18; and the braces and monions, 8 by 10. However, it ought to be observed, that when the gates are very high, the middle rail is made of the same dimensions with the principal pieces: also in sluices above 36 feet wide, the planks of the gates must be $2\frac{1}{2}$ inches thick; or it may answer still better, to lay two rows of plank of that thickness, in order that the seams of the under row may be covered by the planks of the upper one.

SMALLAGE, in botany, a species of apium.

Smallage has the leaves of the stalks wedge-like, and is called by authors apium palustre, peludapium, and eleoselinum. It is aperient and discutive, and its root is one of the five great openers. It is very good in gross constitutions, and infarctions of the lungs, especially if eat with oil and mustard. There needs no trouble to reduce it into any medicinal form, since it may be eaten so conveniently and agreeably in sallads.

SMALT, a kind of mineral matter prepared from cobalt, sometimes in form of a blue powder, and sometimes in cakes. The preparation of zaffre and smalt is as follows.

The cobalt taken out of the mine is broken with hammers, into pieces about the size of a hen's egg; and the stony involucrum, with such other heterogeneous matters as are distinguishable by the eye, as much as possible separated. In this state it is assayed, valued, taxed, tithed, and delivered to the manufactures. In digging the mines the workmen frequently meet with hard sandy masses cutting and interrupting the vein. These are broken in mills; and the cobalt, that had been imbedded in them, separated by sieves.

The mineral, brought to the manufactures, is pounded in stamping-mills, and sifted through brass wire sieves: according to some, the lighter earthy parts are washed off by water. It is then calcined, in a large flat-bottomed, arched furnace, resembling a baking oven, in which the flame of the wood reverberates upon the ore. The mineral is occasionally stirred or turned during the calcination, with long handled iron hooks or rakes; and the process continued till it ceases to emit any fume: an hundred pounds are said to lose twenty or thirty.

Some relate, that the calcination is repeated several times, the ore being taken out and ground into powder each time; others, that it is calcined but once, and the calcination continued from four to nine hours, according to the quality of the cobalt. Some of the assayers lay great stress on the degree of calcination; and report that on this circumstance, not only the beauty of the colour, but the quantity of coloured glass obtainable, in great measure depend; and that the degree of calcination which some cobalts require, would be injurious to others. Some, however, seem to be of opinion, that cobalts may be assayed with sufficient accuracy, both in regard to colour and quantity, without any calcination at all, by barely melting the ore with borax. The cobalt taken out of the calcining furnace is passed through very close brass wire sieves; and such part as has con-

creted

creted into lumps, pounded and sifted afresh, till the whole is reduced into fine powder.

During the preparation of the cobalt, some flints are calcined in another furnace, and thrown red-hot into water; by which they are rendered friable and easily pulverable. The purest and whitest stones are made choice of; or such at least as become white by calcination. In want of these, white sand is used.

Zaffre is composed of one part of the calcined cobalt, and one or two of the calcined flint, mixed together by shaking in a wooden box and sifting, and then moistened with water. Macquer and some others report, that a certain quantity of pot-ash is added to the above mixture, and the whole imperfectly melted. This account has little probability; as the stony powder is very distinguishable in zaffre, without any appearance of its having been united with the cobalt by fusion; and as the masses have the shape of the wooden tubs in which they are brought to us, and consequently cannot owe their hardness to fire.

For making the blue glass, called in the mafs smalt, and when powdered smalts or powder blue; one part of the calcined ore is mixed with one, two, or more of the flint, and one or more of pot-ash; and the mixture melted in large crucibles, in a furnace much resembling that of the glass-house. In each furnace are generally six crucibles, placed about the middle of its height.

The furnace has two doors, one in the front, the other behind: through the latter common billets are put in; through the former, split wood, dried almost to charcoal in an adjoining oven heated by the furnace. In the front door is an aperture, for introducing small assays, which is occasionally closed with a piece of loam. In each side are three apertures for conveying the matter into the crucibles, and, after fusion, taking it out with iron ladles: above these are three others, which are opened occasionally for introducing the tongs to move or settle the crucibles: at the bottom are two more apertures, for taking out the ashes and such part of the glass as may have run out and fallen down among them; this is melted over again.

After the fire has been continued for six hours, the matter is stirred every quarter of an hour, with iron rods, to make the mixture the more equal: the fire is kept up in all, for the best smalt twelve hours, for the inferior kinds eight or ten. The mark of sufficient vitrification is, the glass which adheres to the iron stirrer drawing out into a fine thread. The whole is now taken out with ladles, and poured into a tub of cold water, to render it more easily pulverable.

At the bottom of the crucibles is found a metalline regulus, of a whitish colour, inclining to red, and extremely brittle. When the crucibles have become unfit for any further fusions of the glass, these reguli are melted in them, and are thus resolved into two distinct metallic bodies, one which falls to the bottom, and another which floats above. The first is said to be bismuth; the latter is a semi-metal of a different kind, which yields a blue glass, and accordingly is pulverized and added in fresh mixtures.

The glass appears in the mafs of an opaque deep blue, almost black; when reduced into moderately fine powder, of a pleasant light blue: the further it is comminuted, the paler. It is first beat in a stamping-mill, and passed through a brass-wire sieve, an iron one being apt to rust and spoil the colour: after which, it is ground with water, on a smooth hard stone placed at the bottom of a large vat or tub, by two other hard stones turning vertically: the water, loaded with the fine powder, is let off by cocks into other vessels, and suffered to settle: after the coloured powder has subsided, a white one remains suspended in the water, which is now poured off, that the white matter may settle by itself: this is employed in fresh mixtures, in the room of flint and pot-ash. The coloured powder is washed again, dried in a stove, passed through fine sieves, and divided into different sortments according to the fineness of the powder, and the beauty of the colour. In the last place, it is moistened with a little water, and packed up in casks for exportation.

The richness of cobalt is judged from the quantity of flint and pot-ash with which it will form a sufficiently deep powder blue. The manufactures are provided with assayers, for determining the quantities which different parcels of the ore will bear. The produce of smalt appears to be never less than equal, nor more than four times the weight of the crude ore.

SMARAGDUS, the emerald, in natural history. See EMERALD.

SMECTIS, a name by which some call fuller's earth. See FULLER'S-EARTH.

SMELL, *Odor*, with regard to the organ, is an impression made on the nose, by little particles continually exhaling from odorous bodies: with regard to the object, it is the figure and disposition of odorous effluvia, which, sticking on the organ, excite the sense of smelling: and with regard to the soul, it is the perception of the impression of the object on the organ, or the affection in the soul resulting therefrom.

The principal organs of smelling are the nostrils, and the olfactory nerves; the minute ramifications of which latter are described throughout the whole concave of the former.

According to Boerhaave, the act of smelling is performed by means of odorous effluvia floating in the air, being drawn into the nostrils, in inspiration, and struck with such force against the fibrillæ of the olfactory nerves, which the figure of the nose, and the situation of the little bones, render opposite thereto, as to shake them, and give them a vibratory motion; which action, being communicated thence to the common sensory, occasions an idea of a sweet, or scetid, or sour, or an aromatic, or a putrid object, &c. The matter in animals, vegetables, fossils, &c. which chiefly affects the sense of smelling, Boerhaave observes, is that subtle substance inherent in the oily parts thereof, called spirit; for that, when this is taken away from the most fragrant bodies, what remains has scarce any smell at all; but this, poured on the most inodorous bodies, gives them a fragrantcy.

Willis observes, that brutes have, generally, the sense of smelling in much greater perfection than man; and by this alone, they distinguish virtues and qualities of bodies unknown before; hunt out their food at a great distance, as hounds, and birds of prey; or hid among other matters, as ducks, &c. Man having other means of judging of his food, &c. did not need so much sagacity in his nose; yet have we instances of a great deal, even in man. In the *Histoire des Antilles*, we are assured, there are negroes who, by the smelling alone, can distinguish between the footsteps of a Frenchman and a negroe.

The chemists teach, that sulphur is the principle of all smells, and that those are more or less strong, as the sulphur in the odorous body is more or less dried or exalted. Sulphur, they say, is the foundation of odours, as salt is of flavours, and mercury of colours.

Smell, like taste, consists altogether in the arrangement, composition, and figure of the parts, as appears from the following experiments of Mr. Boyle. 1. From a mixture of two bodies, each of which is of itself void of smell, a very urinous smell may be drawn, that is, by grinding of quick-lime with sal ammoniac. 2. By the admixture of common water, which, of itself, is void of all smell, or inodorous, another inodorous body may be made to emit a very rank smell. Thus camphire dissolved in oil of vitriol, is inodorous, yet, mixed with water, immediately exhales a very strong smell. 3. Compound bodies may emit smells which have no similitude to the smell of the simples they consist of. Thus oil of turpentine, mixed with a double quantity of oil of vitriol, and distilled; after distillation, there is no smell but of sulphur, and what is left behind, the retort being again urged by a more violent fire, yields a smell like oil of wax. 4. Several smells are only to be drawn forth by motion and agitation. Thus glass, stones, &c. which even when heated yield no smell, yet, when rubbed and agitated in a peculiar manner, emit a strong smell; particularly beech-wood, in turning, yields a kind of rosy smell. 5. A body that has a strong smell, by being mixed

with an inodorous one, may cease to have any smell at all. Thus, if aqua fortis, not well dephlegmated, be poured on salt of tartar, till it ceases to ferment, the liquor when evaporated will yield inodorous crystals, much resembling salt of nitre; yet when burnt, will yield a most noisome smell. 6. From a mixture of two bodies, one whereof smells extremely ill, and the other not well, a very pleasant aromatic odour may be gained, viz. by a mixture of aqua fortis, or spirit of nitre, with an inflammable spirit of wine. 7. Spirits of wine, by mixing with an almost inodorous body, may gain a very pleasant aromatic smell. Thus inflammable spirits of wine, and oil of Dantzic vitriol, mixed in equal portions, then digested, and at last distilled, yield a spirit of a very fragrant smell. 8. A most fragrant body may degenerate into a foetid one, without the admixture of any other body. Thus, if the spirit mentioned in the former experiment be kept in a well closed receiver, it will soon turn to the rankness of garlic. 9. From two bodies, one whereof is inodorous and the other foetid, a very pleasant smell may arise, much resembling musk, &c. by putting pearls into spirit of vitriol; for, when dissolved, they yield a very agreeable smell.

SMELL is used as the name of a particular sort of wine, of which there are two species: the one sort is very fragrant, muscatelline, and aromatic; this is called simply the smell-wine; but the other, which is very rank and offensive to the nose, is called by the Germans *smel-bruntzer*. Many have been the conjectures about the occasion of the rank smell of this wine, it not being owing to the grape it is made from, those of the same vineyard often affording the aromatic, and often the rank wine: some have imputed the strange difference to the vessel, others to the vine, and others to the earth it grows in; but the first of these is too trifling a cause for such an effect, and the others are confuted by experience of the same vine, in the same place, yielding both. The opinion of Portzius is, that the rankness of the smell of some of this wine is owing to some irregularities in the working. This is certain, that it never is perceived before the working. The smell is truly urinous, and is that of a volatile alkali; which not being embodied in, or subdued by the acid of the grape, in this imperfect fermentation, shews itself in this rank manner. It is evident that the smell is of a volatile nature, for it is often lost in the drawing the wine several times out of one vessel into another, evaporating during the time of the drawing it out.

SMELT, in ichthyology, the osmerus with seventeen rays in the pinna ani. This is a beautiful little fish; its length is five or six inches, and its breadth not great in proportion, but the thickness is considerable: the head is of an oblong figure, and somewhat acute; the opening of the mouth is large, the back is convex, and the belly somewhat flat; the lower jaw is a little longer than the upper; the nostrils stand in the middle between the eyes and the extremity of the rostrum; they have each two apertures; the eyes are large and round, the pupil is black, and the iris of a silvery white, but tinged a little with blue towards the upper part.

These fish will live almost any where, but they are very apt to degenerate. They are common in the rivers of New-England, and are as large as with us, often weighing two ounces and a half; but, a pail-full of these being taken from one of their rivers, and put into an adjoining pond, they all degenerated in such a manner, that they were afterwards found so small, that the largest did not weigh more than five penny-weights. Though thus small, however, they are much valued, and are better tasted than the others.

SMELTING, in metallurgy, the fusion or melting of the ores of metals, in order to separate the metalline part from the earthy, stony, and other parts.

SMELTING-HOUSE, a house wherein they run and smelt the ore into lead: one of these will run a ton in ten or twelve hours; a fodder is their usual day's work, that is, twenty two hundred and an half weight.

SMITHERY, or SMITHING, a manual art, by which an irregular lump of iron is wrought into an intended shape.

In plate CXXI. *fig. 1.* represents the smith's forge and bellows; *fig. 2.* the anvil set in a wooden block, its

face being A, and B its beak or beak-iron, corruptly called *bickern*; *fig. 3.* and *4.* two kinds of tongs, where A, A are the chaps, B the joint, and C, C the handles; *fig. 5.* represents two kinds of hammers, of which A is the face, B the pen, C the eye, and D the handle; *fig. 6.* is the vice, of which A, A are the chaps, C the screw-pin, D the nut, E the spring, and F the foot; G is a hand-vice; and H, H the pliers; *fig. 7.* is the screw-plate and its tap; and *fig. 8.* a drill.

These are the most essential tools used in the blacksmith's trade; however, as some kinds of work require different tools, we shall here describe a machine for iron-work. A B *fig. 9.* is called the slitting mill, C D the plate mill, and S P the clipping-mill. E and F are two great water-wheels, so disposed that when the water has passed the wheel E in the direction Q W, it comes about the wheel F in the direction X Y. The water-wheel E, with the lantern G on the same axis, carries the spur-wheels, or cog-wheels H, M, with the cylinders B and D: and the wheel F, with the lantern I, carries the cog-wheels K, N, with the cylinders A and C. Now the cylinders A and B, as also C and D, turn contrary ways about; the cylinders A and B are cut into teeth for slitting iron-bars, and are about twelve inches in diameter, whereas C and D are only eight inches in diameter. These cylinders may be taken out and others put in at pleasure; they may also be brought nearer to, or removed farther from, each other, by means of screws which screw up the sockets where their axles turn. The axles of N, I, K, lie all in one horizontal plane; and so do those of M, G, H: but the cylinders A and B, as also C and D, lie one above another.

In order to make iron-plates, if a bar of iron be heated and made thin at the end, and that end put in between the cylinders C and D, whilst the mill is going, the motion of the cylinders will draw it through, on the other side, into a thin plate. Likewise, if a bar of iron be heated and thinned at the end, and put in between the toothed cylinders A and B, it will be drawn through on the other side, and slit into several small pieces, or strings; and then, if there be occasion, any of these strings may be drawn through the plate-mill with the same heat, and fashioned into plates.

In the clipping-mill, O P Q is the sheers for clipping bars of cold iron; V, a cog in the axis of the water-wheel; OP, one side of the sheers made of steel, and moveable about P. The plane L P R is perpendicular to the horizon. When the mill goes, the cog V raises the side OP, which as it rises, clips the bar T Q into two, by the edges S P and R P.

The whole of this engine, except the water-wheels, is within the house.

SMOKE or SMOAK, *fumus*, a humid matter, exhaled in form of vapour, by the action of heat, either internal or external.

Smoke, Sir Isaac Newton observes, ascends in the chimney by the impulse of the air it floats in; for that air being ramified by the fire underneath, has its specific gravity diminished; thus, being determined to ascend itself, it carries up the smoke along with it. The tail of a comet that great author takes to ascend from the nucleus after the same manner.

SMOKE-JACK, a very simple and commodious machine, in a kitchen; so called from its being moved by means of the smoke, or rarified air, moving up the chimney, and striking against the tail of the horizontal wheel, A B (plate CXIV. *fig. 8.*) which being inclined to the horizon, is thereby moved about the axis of the wheel, together with the pinion C, which carries the wheel D and E; and E carries the chain F, which turns the spit.

The wheel A B should be placed in the narrow part of the chimney, where the motion of the smoke is swiftest, and the greatest part of it must strike upon the sails. The force of this machine is so much greater, as the fire is greater.

SMUGGLERS, in law, those persons who conceal or run prohibited goods, or goods that have not paid his majesty's customs.

SMUT, in husbandry, a disease in corn, in which the grains, instead of being filled with flour, are full of a black stinking powder.

Many

Solid of least resistance.

A Machine used in Smithery for making & Slitting Iron Plates

Many things have been suspected as the causes of this distemper in corn; but Mr. Tull seems convinced by experiment, that it is caused only by too much moisture, the several plants of corn, which he had taken up by the roots and planted in troughs of very moist earth, all bringing forth smutty ears, while very few such were found in the corn of the field from whence these plants were taken. It is observable, also, that those ears, the grains of which are to be smutty, never send up any flowers at all.

The two things recommended by writers of husbandry as remedies or preventions of this disease, are brining and changing the seed. The first of these methods was accidentally discovered about a century ago: A ship loaded with wheat was, about autumn, sunk near Bristol, afterwards the wheat was taken up at the ebbs at several times, after being thoroughly soaked in sea water. When the wheat was all taken up, it was found unfit to make bread of; but a farmer, trying some of it for sowing, found it answer very well, and himself and the neighbouring farmers bought it all up at a small price; the country all about was sown out of this cargo. It happened that smuttiness in the wheat-corn was a reigning distemper in all parts of the kingdom at that time, but it was remarkable, that all the fields sown with this salt wheat were absolutely free from the mischief: this easily introduced the practice of soaking wheat, before sowing, in a brine of salt and water, to prevent it in other places, and it has succeeded well. Mr. Tull gives an instance of the certainty of its effect, in the case of two farmers whom he personally knew, and whose farms lay intermixed: these men bought the same seed between them from a very good change of land, and parted every land between them in the field; the oldest farmer believed the brining to be a fancy, and sowed his seed unbrined; the other brined all his seed, and the consequence was, that the old farmer had a great deal of smut in his corn, while the other had not one smutty ear.

When wheat is intended for drilling, it must be soaked in no other brine than that of pure salt and water; for, if there be any grease among it, it will never be dry enough for this manner of sowing. If seed wheat be soaked in urine, it will not grow; and if it be only sprinkled, it will most of it die, unless it be planted presently. The most expeditious way of brining wheat for drilling, is to lay it in a heap, and wash it with a strong brine sprinkled on it, stirring it up with a shovel, that it may be all equally brined or wetted with it: after this, sift on some fine lime all over the surface, and stir it up, still sifting on more in the same manner, till the whole is dusted with the lime; it will then be soon dry enough to be drilled without farther trouble. It must be quicklime, in its full strength, that is used on this occasion.

Bad years will cause smut in corn, and good years will prevent it: it is, however, observable, that the crops in which there is smutty corn, will, if used for seed, be liable to produce smutty corn again, rather than other seed. The brining is a defence against bad years, and against the mischiefs attending the sowing corn among which there has been smut.

Seed-wheat should be brought from the crop on a strong clay land, whatever kind of land it is to be sowed upon. A white clay is a good change for a red clay, and a red clay for a white; but whatever the land be, from which the seed is taken, it may be infected, if that be not changed there the preceding year; and then there may be danger, though it be had from ever so proper a land. It is a rule among the farmers, never to buy seed-wheat from a sandy soil; they express their dislike of this by the coarse rhyme, "Sand is a change for no land."

A crop of wheat, very early planted, is not so apt to be smutty, as one planted less early; and the farmers have observed, that the largest and plumpest ground for wheat is more liable to be smutty than the small ground wheat. *Tull's Horse-hoeing Husbandry.*

SNAPPLE, in the manege, is a very slender bit-mouth, without any branches, much used in England; the true bridles being reserved for the service of war.

The snaffle, or small watering-bit, is commonly a scratch mouth, with two very little straight branches, and a curb, mounted with a head-stall, and two long reins.

SNAIL, *Limax*, in natural history, a genus of the gymnarthria, or naked insects, the body of which is of a figure approaching to cylindric, and is perforated at the side: the tentacula, or horns, as they are called, are four in number, and two of them have the appearance of eyes.

There are a great many species of snails, whereof we shall only mention a few. 1. The black naked snail, a considerably large insect, being commonly three inches long, and half an inch broad; its whole body is furrowed and much wrinkled, and is of a deep black, except the belly, which is grey.

2. The naked reddish snail grows only to about two inches in length, and is also covered with numerous slight furrows.

3. The amber-coloured snail, when full grown, is only about an inch and a half long: its colour is a glossy yellow, with a cast of brown in it, and the whole body is variegated with spots of a greyish colour.

4. The oat snail, a name given by Dr. Lister, in the Philosophical Transactions, to a small snail, which he observed under the loose bark of old willows, elms, and other trees, and which is of a very singular structure; the shell resembling an oat corn, whence the name and its volutæ, or wreaths, running contrary to the direction of them in other snails, that is, east and west, as the philosophers express it, referring it to the motion of the sun; but these shells, to use that language, have the turns west and east, or, more plainly, they have the turns running from the right hand to the left, not from the left to the right, as other snails. *Phil. Trans. Num. 250.*

Snails are great destroyers of fruit in our gardens, especially of the bitter sorts of wall-fruit. Lime and ashes, sprinkled on the ground where they most resort, will drive them away, and destroy the young brood of them. It is a common practice to pull off the fruit they have bitten; but this never should be done, for they will eat no other till they have wholly eat up this, if it be left for them.

The Romans were fond of snails, and had them fed on-purpose for their tables. Their taste is not delicious, but rather disagreeable; but this they disguised by means of good sauces, and had other reasons for the receiving them into the lists of foods.

They used them as provocatives or inciters to venery, and with this intent they eat only the necks, as the part in which the parts of generation of the creature were placed; and they had the greater opinion of the efficacy of these, as the parts of generation were double in each individual, that is, the male and female parts both situated in the neck of every snail.

Aristotle, and the old Greeks, had no idea of the generation of these insects in the manner of other animals, but supposed them produced spontaneously; but the Romans shew by many passages in their writings, that they had got over this error, and even seem, by the preference they give to the neck of this animal, in this intention, to have understood the hermaphrodite structure of this insect, which much later ages have pretended to make a new discovery.

The eastern nations at present entertain the same opinions of the old Romans, as to provocatives; they use, as the others did, every thing that serves to the purposes of generation in other animals, and every thing that has but the resemblance of the external figure of the parts subservient to it. The orchis roots, which resemble the testicles of animals in shape, and contain a white and slimy, or viscous liquor, have introduced themselves into use on this plan, and so of many other things.

SNAKE, *Anguis*, in natural history, the name of a well known reptile, of the serpent kind.

The common snake is a harmless and inoffensive animal, and might even be kept tame in houses, to destroy vermin.

Its flesh is restorative, like that of the viper. See VIPER.

SNAKE with two Heads, a kind of snake in Brasil, having a swelling at his tail, which, at a distance, has the appearance of a head.

The Portuguese call it snake with two heads; their fear of this creature, for the bite of which they pretend there is no remedy, having prevented their examining into the truth. They also pretend that it is dangerous to meddle with these snakes after they are dead, and that barely touching them will give the itch. Mr. Couplet was, notwithstanding, bold enough to slay several of them, but found himself, after having performed this operation on two or three, all covered with pustules filled with a reddish water. These remained on him a considerable time, and he was not quite well in three months.

The country of Brasil abounds with large snakes, the bite of which is venomous, but the natives and blacks make no scruple of eating them.

SNAKE-ROOT. See the article SERPENTARIA.

SNAPDRAGON, in botany, a genus of plants, the flower of which consists of one leaf of a tubular form, personated, and having two lips, the upper of which is bifid, and the lower trifid. The pistil arises from the cup, and is fixed, in the manner of a nail, in the hinder part of the flower; and afterwards becomes a seed-vessel, of the shape of the head of a hog, divided into two cells, and usually filled with small seeds fixed to a placenta.

Many of the species of this plant are very beautiful, and much esteemed in gardens, and are all easily propagated from seeds, which must be sown in a dry soil, not too rich, in April or May. In July the plants may be planted out into large borders, where they will flower the spring following; or they may be sown early in the spring, and they will then flower in the next autumn; but then they are not so likely to stand the winter, and, if the autumn proves not kindly, they will hardly produce a perfect thin seed. They all grow very well on old walls, where they have happened to sow themselves.

SNEEZING, *Sternutatio*, a convulsive motion of the muscles of the breast, used in expiration: wherein, after suspending the inspiration begun, the air is repelled from the mouth and nose, with a momentary violence and noise.

The cause is an irritation of the upper membrane of the nose, which communicates with the intercostal nerve by means of the twigs that it detaches to it.

This irritation is performed either externally, by strong smells, as marjoram, roses, &c. or by sharp, pungent, medicines, as cresses and other sternutatories, which vellicate the membrane of the nose; or internally, by the acrimony of the lymph or mucus, which naturally moistens that membrane.

SNOW, *Nix*, a meteor formed, in the middle region of the air, of vapours raised by the action of the sun, or subterraneous fire; there congealed, its parts constricted, its specific gravity increased, and thus returned to the earth in little white villi, or flakes.

The snow we receive, may properly enough be ascribed to the coldness of the atmosphere through which it falls. When the atmosphere is warm enough to dissolve the snow before it arrives at us, we call it rain; if it preserve itself undissolved, it makes what we call snow.

Dr. Grew, in a discourse of the nature of snow, observes, that many parts thereof are of a regular figure, for the most part so many little rowels or stars of six points, and are perfect and transparent ice, as any we see on a pond, &c. Upon each of these points are other collateral points, set at the same angles, as the main points themselves; among which there are divers other irregular, which are chiefly broken points, and fragments of the regular ones. Others also, by various winds, seem to have been thawed and froze again into irregular clusters; so that it seems as if the whole body of snow were an infinite mass of icicles irregularly figured; that is, a cloud of vapours being gathered into drops, the said drops forthwith descend; upon which descent, meeting with a freezing air, as they pass through a colder region, each drop is immediately froze into an icicle, shooting itself forth into several points; but these still continuing their descent, and meeting with some intermitting gales of warmer air, or in their continual

waftage to and fro, touching upon each other, some of them are a little thawed, blunted, and again froze into clusters, or intangled so as to fall down in what we call flakes.

The lightness of snow, although it is firm ice, is owing to the excess of its surface, in comparison to the matter contained under it; as gold itself may be extended in surface, till it will ride upon the least breath of air.

The uses of snow must be very great, if all be true Bartholin has said in its behalf, in an express treatise, *De Nivis Ufu Medico*; he there shews, that it fructifies the earth, which indeed, is a very old and general opinion, preserves from the plague, cures fevers, cholics, tooth-achs, sore-eyes, and pleurifies, for which last use, his countrymen of Denmark use to keep snow-water gathered in March. He adds, that it contributes to the prolongation of life; giving instances of people in the Alpine mountains that live to great ages; and to the preserving dead bodies, instances whereof he gives in persons buried under the snow in passing the Alps, which are found uncorrupted in the summer, when the snow is melted.

He observes, that, in Norway, snow-water is not only their sole drink in the winter, but snow even serves for food; people having been known to live several days, without any other sustenance.

Indeed the generality of these medicinal effects of snow are not to be ascribed to any specific virtue in snow, but to other causes. It fructifies the ground, for instance, by guarding the corn or other vegetables from the intense cold of the air, especially the cold piercing winds. And it preserves dead bodies, by constricting and binding up the parts, and thus preventing all such fermentations or internal conflicts of their particles, as would produce putrefaction.

Snow may be preserved by ramming it down in a dry place, under-ground, and covering it with chaff, in the manner of ice.

SNUFF, a powder chiefly made of tobacco, the use of which is too well known to need any description here. See TOBACCO.

SOAP, or *Sope*, in commerce, and the manufactures, a kind of paste, sometimes hard and dry, and sometimes soft and liquid, and much used in washing, whitening linens, and by dyers, fullers, &c. The principal soaps of our manufacture are the soft, the hard, and the bole soap; all which consist of an intimate union of the salt of pot-ash with oil, or animal fat.

The fine hard white soaps are made with oil olive and an alkali acuated with quick-lime, which promotes the action of the salt upon the oil, and at the same time disposes the soap to a hard and dry consistence, which it does not easily assume when made with plain alkali. I have tried to prepare soap with alkaline ley alone, and with lime water alone: with the first, the soap turned out softish and unctuous: with the latter, I obtained, not a true soap, but a hard brittle compound, from which the oil separated on trying to dissolve it in water. A quantity of common salt is generally added in the process, but it does not enter the composition of the soap: The use of this salt is, when the oil has been incorporated, by boiling, with the alkaline salt of the ley, to promote the separation of the saponaceous concrete from the water: it is only at this period that the sea-salt is added. The sea-salt may be recovered from the remaining liquor by crystallization; if any part of it happens from unskilful management, to be retained in the soap, it separates in little crystals as the soap dries.

The greatest quantities of soap are made in Spain, Portugal, France, and Italy; oil-olive being in those countries most plentiful. The most common and cheapest, of the foreign soaps, is that of Venice. I have seen the preparation of this sort: it is made from three parts of good oil-olive, and two of a caustic ley; which ley is drawn from two parts of Spanish soda and one of quick-lime, with a suitable quantity of water. No metalline vessels are made use of: the boilers are composed of building stone, joined by a particular cement, and secured with iron cramps: in these the oil and ley, to the quantity of some hundred weights at a time, are kept gently simmering for several days and nights. The Venetians

netians prepare also a green sope, from old oil, the mother ley of the white sope, and other refuse matters, adding a certain portion of the juice of beet-leaves, which communicates the green colour: the juice is pressed out by a horse-mill consisting of an horizontal stone, with a perpendicular one turning upon it, as in the gun-powder-mills. The common coarse sopes are made with tallow: and the soft, blackish, and greenish sorts with train oil.

Fixed alcalies unite much more difficultly with essential oils than with the expressed. For making a sope with oil of turpentine, formerly celebrated as a medicine under the names of Sope of Tartar, the Universal Corrector, &c. different processes have been pursued, and all of them tedious or defective. Some mix the oil of turpentine with a well calcined salt of tartar, and stir them together every day for half a year or longer, till the union is completed: some dry the mixture occasionally, as often as it is found to have imbibed moisture from the air. Some have secured the mixture in a strong glass fixed to the clapper of a mill or the sail of a wind-mill, that by this means it might be kept in constant agitation: but simple agitation is not sufficient. Some boil the oil with a caustic ley, keeping the whole continually stirring, nearly in the same manner as for making sope with expressed oils. Others pulverize the salt, strongly heated, in a mortar, and pour upon it whilst very hot, the oil of turpentine likewise heated: by this method a sope is most expeditiously obtained, but the more subtle parts of the oil are dissipated. The best way is to mix the oil and salt together moderately hot, and digest them in a low glass body for a day, then grind and digest them again. It is not of much importance to be curious about the proportions: if the salt predominates, the oil will the more readily and more perfectly unite with it, and when the union is obtained, the superfluous salt may be separated by deliquation: the process may be finished by drawing over several times from the sope some rectified spirit of wine, by which, if there is any redundant oil, it will be in good measure separated. The other essential oils are still more difficultly combinable with alcalies than that of turpentine; but empyreumatic oils unite more easily. Volatile alcalies do not form a sope with any kind of oil: they only thicken expressed oils into the consistence of a liniment; and it is only the spirit of sal ammoniac made with quick-lime that does this.

Common hard sope dissolves in water, though not perfectly, by virtue of its alkaline salt. But it dissolves also, and that in a more perfect manner, in rectified spirit of wine, though this menstruum has no action either on the oil or the salt by themselves: it is observable, that a small proportion of sope gives a quite thick consistence to a very considerable quantity of the spirit. On adding any acid to a solution of sope, its ingredients separate from one another, the alcali being absorbed by the acid, and letting go the oil. Sope is used medicinally as a detergent and deobstruent: it dissolves tenacious mucus, and promotes the natural excretions. If there are any medicines capable of dissolving the calculus in the bladder, sope is one of the principal. *Neumann's Chemistry.*

Almond SOAP, Amygdalinus, a new form of medicine got much into use of late in nephritic cases, and made to supply the place of the common hard soap for internal uses, in a more determinate manner for the physician, and a more cleanly one for the patient.

It is thus made:—Take any quantity of fresh oil of almonds, and thrice its quantity of soap lees; digest them together in such a heat as will make them but just boil; within a few hours the oil and lees will be united, and the liquor will soon after become ropy, and something transparent, and will cool into the consistence of a jelly; then throw in sea-salt till the boiling liquor has lost its ropiness; continue the boiling till, drops of the liquor being received upon a tile, the water is seen to separate freely from the coagulated soap; then take away the fire, and the soap will rise to the top of the water, and is to be taken off for use.

SOAP-EARTH, Steatites, a smooth unctuous kind of earth found in the Levant, and used as a sope.

The sope-earth, Dr. Smith tells us, is only had in

two places near Duraclea, six leagues to the east of Smyrna. It is in effect of itself a fine sope, boiling and shooting up out of the earth.

It is gathered always before sun-rise, and in mornings when there falls no dew, so that a stock must be laid up in the summer months to serve all the year. In some places it comes up an inch or two above the surface of the ground, but the sun rising on it makes it fall again. Every morning there returns a fresh crop.

The people of Duraclea make soap with this earth in the following manner: they mix three-fourths of this earth with one fourth of lime, and then pour boiling water upon the mixture; they stir this with a stick, and there arises to the top a thick brownish substance, which they scum off; they save this in vessels by itself. They use both this and the clear liquor in making soap, but this is much stronger than the liquor. They put fifty kintals of oil into a large copper furnace, and, kindling a large fire under it, they let the oil boil a little, and then throw in, by little and little, first the scum of the ley, and afterwards the liquor itself; though sometimes they use only the one, or only the other. They continue adding more and more of these till the oil acquires the consistence of soap, which is often several days. The fire must be all this time kept up very strong. The scum of the ley, and the stronger part of the ley itself, mix with the oil in the boiling, and the weaker part, unmixing itself, sinks to the bottom, and is let out by a cock prepared for that purpose. This is not thrown away, but is let run upon fresh lime and earth, to make a ley for future use; and, when the soap is perfectly made, it is ladled out, and put upon a brick or lime floor to harden.

The common proportion, in the making the soap, is two loads of earth of five kintals each, to fifty kintals of oil, and the produce is between seventy and eighty kintals of soap. The earth is bought at a dollar a load, and the soap at six-pence half-penny a kintal. There are employed annually, in making soap at Smyrna, at least ten thousand kintals of oil. The bringing the soap earth to Smyrna employs a thousand or fifteen hundred camels for eight months of the year, the four summer months being too hot for camels to travel in. A common soap-house produces, at a medium, a thousand dollars a year clear profit. *Phil. Transf. N^o. 220.*

There is great reason to believe that, when we know the proper manner of working, this will, one way or other, make a great ingredient in our porcelain manufactures.

The Chinese have of late discovered a sort of earth which they call hoache. They say that this is hard, smooth and soft to the touch, like soap; these, and its other qualities, seem to prove it to be the same with our soap-rock, and this, with them, makes a sort of porcelain, superior to the common kind in beauty, and in the compactness of its texture; but it is more apt to crack. They use it several ways, sometimes alone, sometimes with the petunse, which is a stone; and sometimes they make a varnish, by dissolving this in water, with which they coat over the common china, covering it finally with the other varnish. All these ways of using it produce very beautiful wares, and it will be extremely worth our while to try them all round, before we give up the use of so valuable a thing. *Observ. sur les Coutumes de l'Asie.*

SOAR-HAWK, an appellation given to an hawk; from the time of taking her from the eyrie, till she has mewed, or cast her feathers.

SOCIETY, Societas, in general, denotes a number of persons united together for their mutual assistance, security, interest, or entertainment.

The social principle in man is of such an expansive nature, that it cannot be confined within the circuit of a family, of friends, or a neighbourhood: it spreads into wider systems, and draws men into larger communities and common-wealths; since it is in these only, that the more sublime powers of our nature attain the highest improvement and perfection of which they are capable.

In society, the mutual aids which men give and receive, shorten the labours of each; and the combined

strength and reason of individuals give security and protection to the whole body. There is a variety of genius among mankind; some being formed to lead and direct others, to contrive plans of employment for individuals, and of government for communities, to invent laws and arts, and superintend their execution, and in short to refine and civilize human life: others again, who have not such good heads, may have honest hearts, a true public spirit, love of liberty, order, &c. and finally, others seem best disposed for manual exercises, as bodily labour. Society finds a proper employment for every genius, and the noblest objects and exercises for the noblest geniuses. In society, a man not only finds more leisure, but better opportunities of applying his talents with success.

From this short detail it appears, that man was formed for society; which rests on these two principal pillars. 1. That it affords security against those evils which are unavoidable in solitude. 2. That it enables us to obtain those goods, some of which cannot be obtained at all, and others not so well, in a state of solitude, wherein men depend wholly on their own sagacity and industry.

Royal Society of England, is an academy or body of persons of eminent learning, instituted by king Charles II. for the promoting natural knowledge. This illustrious body had its original in an assembly of ingenious men, who before the Restoration met weekly in Wadham college, at the lodgings of Dr. Wilkins.

Afterwards, from about the year 1658, many of them living in London, held meetings at Gresham college, till they were at length taken notice of by the king, who was pleased to grant them an ample charter, dated April 22, 1663; whereby they were erected into a corporation, consisting of a president, council, and fellows, for promoting the knowledge of natural things and useful experiments.

Their manner of electing fellows is by balloting. Their council are in number twenty-one, eleven of which are continued for the next year, and ten more added to them, all chosen on St. Andrew's day.

Each member at his admission subscribes an engagement that he will endeavour to promote the good of the society; from which he may be freed at any time, by signifying to the president, that he desires to withdraw.

The charges are forty shillings paid to the treasurer at admission, and thirteen shillings per quarter, so long as he continues a member.

Their design is to make faithful records of all the works of nature or art which come within their reach; so that the present, as well as after ages may be enabled to put a mark on errors which have been strengthened by long prescription, to restore truths that may have been neglected, to push those already known to more various uses, to make the way more passable to what remains unrevealed, &c.

To this purpose they have made a great many experiments and observations on most of the works of nature, eclipses, comets, meteors, mines, plants, earthquakes, inundations, springs, damps, subterraneous fires, tides, currents, the magnet, &c. Also, numbers of short histories of nature, arts, manufactures, useful engines, contrivances, &c. The services they have been of to the public are very great. They have improved naval, civil, and military architecture; advanced the security and perfection of navigation; improved agriculture; and put not only this kingdom, but also Ireland, the plantations, &c. upon planting.

They have registered experiments, histories, relations, observations, &c. and reduced them into one common stock, and have from time to time published some of the most immediate use under the title of Philosophical Transactions, &c. and laid the rest up in public registers to be transmitted to posterity as a solid ground-work for future systems.

They have a library adapted to their institution, towards which the late Marshal contributed the Norfolkian library, and a museum, or repository of natural and artificial rarities, given them by Daniel Colwal, Esq; and since enriched by many others. Their motto is *Nullius in Verba*.

SOCIETY for the Reformation of Manners, and putting in execution the laws against immorality and profane-

ness. It was set on foot, about thirty years ago, by five or six private persons in London, but is since exceedingly increased by numbers of all denominations. A particular body of the most considerable hereof bear the expence of prosecutions, &c. without any contribution from the rest. These chiefly apply themselves to the prosecuting people for swearing, drunkenness, and prophaning the sabbath. Another body, of about fifty persons, apply themselves to the suppressing lewdness, and by them above five hundred lewd houses have been actually suppressed; a third body consists of constables; and a fourth of informers. Besides these, are eight other regular mixed bodies of house-keepers and officers, who inspect the behaviour of the constables and other officers, assist in searching disorderly houses, seizing offenders, giving information, &c. There are several other societies of this kind at Bristol, Canterbury, Nottingham, &c.

SOCIETY for propagating the Gospel in foreign Parts, was instituted by king William, in 1701, for securing a maintenance for an orthodox clergy, and making other provisions for the propagation of the Gospel in the plantations, colonies, frontiers, &c. To that end he incorporated the archbishops, several bishops, and other nobility, gentry, and clergy, to the number of ninety, with privilege to purchase two thousand pounds per year, inheritance and estates for lives, or years, with other goods to any value.

They meet yearly on the third Friday in February, to chuse a president, vice-president, and other officers; and the third Friday in every month to transact business, depute fit persons to take subscriptions for the said uses, and of all monies so received to give account to the lord chancellor, &c. They have a standing committee at the chapter-house, to prepare matters for the monthly meeting, which is held at St. Martin's library.

SOCIETY for propagating Christian Knowledge. This was begun in 1699, by some persons of worth, &c. Its original design was to propagate religion in the plantations, to secure the pious education of the poor at home, and to reclaim those that err in the fundamentals of Christianity. In the year 1701, they had procured considerable charities, and transmitted the same to the plantations, in libraries, bibles, catechisms, &c. with a voluntary maintenance for several ministers to be employed in the plantations; but the Society for propagating the Gospel in Foreign Parts being then instituted, they were incorporated by charter in the same, and thus discharged as a particular society from the further pursuit of that branch of their original design, whereupon they wholly turned themselves to the other, and are now very considerable by great accessions from the clergy and laity.

They meet weekly to concert measures for raising charity for educating poor children, and setting up schools for that purpose, as also for the more regular disposal of books for the instruction of the ignorant, erroneous, &c.

SOCINIANS, in church history, a sect of Christian heretics, so called from their founder Faustus Socinus, a native of Sienna in Italy.

This heresiarch, from his youth, gave proofs of a fine and extensive genius: but the misfortune he had of imbibing very early the doctrines of Michael Servetus gave a wrong bias to his judgment. Being afraid lest his opinions should expose him to the severities of the inquisition, he left Italy, and retired into France. About the year 1574, he began openly to declare against the Catholic faith. At first he joined himself with Blandratus in Transylvania; and they both endeavoured to establish, in that country, the doctrines of Servetus against the mystery of the Holy Trinity, and all the other errors of that sectarist. The applauses Socinus received from all the heretics who at that time infested Transylvania, flattered his vanity, and inspired him with a design of establishing a religion entirely new. He began with publishing, that Luther, Calvin, and other reformers, had indeed purged religion from many superstitions, which had been introduced into it, but that they had not entirely purified it. Afterwards he openly declared against the doctrine of the Trinity, and taught,

1. That

1. That the Eternal Father was the one only God; that the word was no more than an expression of the god-head; and had not existed from all eternity: and that Jesus Christ was God no otherwise than by his superiority above all creatures, who were put in subjection to him by the Father. 2. That Jesus Christ was not a mediator between God and men, but sent into the world to serve as a pattern of their conduct; and that he ascended up to heaven only, as it were, to take a journey thither. 3. That the punishment of hell will last but for a certain time, after which both body and soul will be destroyed. And, 4. That it is not lawful for princes to make war.

These four tenets were what Socinus defended with the greatest zeal: in other matters, he was a Lutheran or a Calvinist. The truth is, he did but refine upon the errors of all the Anti-trinitarians who had gone before him.

The Socinians spread extremely in Poland, Lithuania, and Transylvania. Their chief school was at Racow, and there all their first books were published. Their sentiments are explained at large in their Catechism, printed several times under the title of *Catechesis Ecclesiarum Polonicarum unum Deum patrem, illiusque filium unigenitum, una cum Sancto Spiritu, ex sacra scriptura constituntur*. They were exterminated out of Poland in 1655, since which time they have been chiefly sheltered in Holland: where, though their public meetings have been prohibited, they find means to conceal themselves under the names of Arminians and Anabaptists.

SOCLE, or ZOCLE, in architecture, a flat square member under the bases of pedestals of statues, vases, &c. which serves as a foot or stand. Continued socle is a kind of continued stand or pedestal without either base or cornice, ranging round the whole building, called by Vitruvius *stereobata*.

SOCRATIC PHILOSOPHY, the doctrines and opinions, with regard to morality and religion, maintained and taught by Socrates. By the character of Socrates, left us by the ancients, particularly by his scholar Plato, Laertius, &c. he appears to have been one of the best and the wisest persons in all the heathen world. To him is ascribed the first introducing of moral philosophy, which is what is meant by that usual saying, "That Socrates first called philosophy down from heaven to earth;" that is, from the contemplation of the heavens and heavenly bodies, he led men to consider themselves, their own passions, opinions, faculties, duties, actions, &c.

SODA, or HEAT of the Stomach, in medicine, the name of a distemper consisting in a heat or troublesome burning about the pit of the stomach, or its left mouth, which sometimes is extended the whole length of the oesophagus, with a pressure or spasmodic constriction, usually attacking the patient by fits. The cause is generally fat aliment, especially veal, if cold drink be taken soon after. In some it proceeds from acids, in others from aromatics, spirituous liquors, or bilious humours. This disorder is generally slight, and vanishes of its own accord, though in others it is of long duration. In the cure, the cause must always be attended to; if from acids, absorbents are proper, particularly crabs-eyes and prepared shells, mixed with a fourth or fifth part of powder of nutmeg given to half a dram, as also the *tabellæ cardialgicæ*. It is common to take chalk alone or mixed with nutmeg; but care should be taken not to be too free in its use. Oil of tartar per deliquium, given from twenty to thirty drops in coffee, tea, broth, or warm beer, is generally efficacious, as also tincture of tartar and spirit of hartshorn. If it proceeds from bilious humours, thirty or fifty drops of dulcified spirit of nitre in water, tea, or coffee, will take away the pain. When it is caused by fat things and draughts of cold liquor, a dram of brandy is good. Now and then laxatives should be given to carry off the humours. In sanguine constitutions, bleeding may be proper.

SOFA, in the Turkish customs, a kind of alcove, raised half a foot above the floor of a chamber or other apartment, and esteemed the place of state where visitors of distinction are received.

SOFFITA, or SOFFIT, in architecture, any timber ceiling, formed of cross beams of flying corniches, the square compartments or pannels of which are enriched with sculpture, painting, or gilding; such are those in the palaces of Italy, and in the apartments of Luxembourg at Paris. This word is particularly used for the under side or face of an architrave, and for that of the corona or larmier, which the ancients called *lacunar*; the French *plafond*, and we usually the *drip*. It is enriched with compartments of roses, and has eighteen drops in the Doric order disposed in three ranks, six in each, placed to the right-hand of the *guttæ*, and at the bottom of the *triglyphs*.

SOFTENING, in painting, the mixing and diluting of colours with the brush or pencil. To soften designs in black and white made with the pen, &c. signifies to weaken the tint. To soften a portrait, according to Felibien, is to change some of the strokes, and give a greater degree of sweetness and softness to the air thereof, which before had something rough and harsh in it.

SOIL, *Solum*, in agriculture and gardening, denotes earth or ground considered with regard to the quality of its mould for the product and growth of vegetables.

Mr. Bradley reduces all soils to three heads, viz. sand, loam, or mother-earth, and clay. — Gravels, and all the open soils till we come at loam, are of the sandy race; and the binding earths from loam, down to the stiffness of chalk, may be ranged under the clay kind.

Loam, or mother-earth, is the medium between the two, and includes all the intermediate kinds.

Each of these soils tends likewise to vegetation, and each has its salts proper thereto; but in different proportions, a peck of clay having twice as much salts in it as the same quantity of loam, and four times as much as sand.

Now, it is found to be the salts or juices of the soil, not the earth itself, that plants are fed and subsisted by. For, in many experiments of vegetation where plants of fifteen or twenty pounds weight have been produced, there has been no sensible diminution of the weight of the earth.

Hence, at first, it would seem that clay were most proper, and sand the least proper soil, to promote the growth of plants, which is contrary to experience. The reason is, that the parts of clay, being close wrought together, do not so easily give out their salts, nor can the tender fibres of many plants make their way through it in search of their food. But, if its parts be well opened by digging and breaking it into very small pieces, and those parts be kept open by a mixture of sharp sand, or other like matter, that author adds, we shall see the effect of its vigour; sand, on the other hand, giving its salts readily, puts forth its plants very easily, and will make them generate a full month sooner than clay; but, as it is hasty, it is soon spent. The sun's warmth calls up all its warmth early in the spring, and there is but little left for them to subsist long on, if the heat continue.

The land of England, as considered by the farmer, is reduced into nine sorts of soils; the sandy, the gravelly, the chalky, the stony, the rocky, the hazely, the black earth, the marsh, and the clay land. Of this kind there are four varieties, distinguished by their colours: the black, the blue, the yellow, and the red. In many places these soils are mixed and blended together, and where it is so, it is much better than where they are separate or single; especially where the mixtures happen to be of a right kind, as those of the hot and dry soils blended with the cold and the moist. Nature does this often, and art may imitate it. All sands are hot, and all clays are cold; and therefore the laying clay upon sandy lands, or sand upon clayey lands, is the best of all manure: this alters and changes for the better the very nature of the land itself, whereas dung only improves it for a time, and after that leaves it as bad as it was before. Mixed soils, that tend to the clayey kind, are the best of all others for corn. It is not only the natural soil we are to consider, but the depth of it, and what soil is underneath; for the richest soil, if it be only eight or ten inches deep, and lies upon a cold clay, or upon stones, will not be so fruitful to the farmer as the leaner soils that lie upon better under strata. Gravel

or sand are the best under-strata, of all others, to make the land above prolific.

Cold and wet clays are much more fruitful in the southern parts of England, than in the north. The climates, therefore, are to be considered, and the quantities or proportions of the different kinds in the mixed soils. The natural produce of the land, as to weeds or grass, is also to be greatly regarded by the person who intends to improve upon it.

What is the effect of plowing is next to be enquired into, and experiment must shew what kind of corn agrees best with it.

All land that moulders into dust with frost, with all sorts of warm lands, black mould, yellow clays, if not too spewy when wet, and all that turn black after rain, are in general good lands for corn. Land that produces large trees, as also such as produces black-thorn, weeds, thistles, rank grass, and the like, and that lies in bottoms open to the east or south, being well sheltered from the other winds, may be always esteemed to bid fair for good land. Thyme, strawberries, betony, and wild sage, direct to the places where wood will thrive best; and camomile is always an indication of a land being disposed to bear corn in large crops.

All land that binds after frost and rain, all that turns white, and is full of worms, or is very moist and cold, or that is too hot and dry, and that lies open to the north on the sides of hills, exposed to cold winds and frosts in winter, and to the sun's scorching heat in summer; and all that bears naturally holly, box, ivy, juniper, fern or brakes, furzes, broom, and heath; and lands that bear mosses, rushes, yarrow, and wild tansy, with flags, and other such weeds, which betoken a cold and damp ground; are less fit for corn, though other things may succeed on it. Where plants appear blasted, shrubby, and curled, these are distempers in them occasioned by sudden changes of wet and cold, and a dry heat. All these lands are, by their natural produce, to be judged less fruitful than the others. Blackish, dun, or yellow land, and very hot stony gravel, are generally esteemed very unfruitful. Chalky lands are naturally cold, and therefore they require warm composts; and this is the reason why chalk itself is so good a manure for hot and dry land. Sandy land, well manured with marl, will bear turnips, or white or blue pease, to great advantage. *Mortimer's Husbandry.*

The supply of fresh vegetable matter, in the place of that which was drained away by the successive growths of plants, is done by several ways, but by none so well, as by letting it lie fallow for some time; in this case the rain falling upon it, the vegetable earth, which this water contains, is deposited in sufficient quantity, and this is alone sufficient to give nutriment to new crops; and it is proved by this, that the rain water, as well as other water, does contain such earth as is necessary to vegetation. The other means of giving a supply to the exhausted earth are the manures laid on it by the farmer, and these are, all of them, some animal or vegetable remains, and their use is to drain into the earth those particles from themselves, which may be again received into the bodies of new productions of the same kinds. Blood, urine, the excrements of animals, with their several parts, as horns, hoofs, hair, feathers, calcined shells, and vegetable bodies in an altered state, such as lees of wine and beer, ashes of burnt vegetables, leaves, straw, roots, stubble, and the like, when in a decaying state, turned under the earth again by plowing, there become disunited into their component parts, and these again are carried up into other new plants.

If we take off our thoughts from the fields, and look among the gardens, we there meet with farther confirmations of the same thing; the trees, shrubs, and herbs cultivated in these, after they have continued in one station, till they have derived thence the greater part of the matter fitted for their increase and nourishment, will either decay, or degenerate, unless they have a new supply of manure added to the earth about their roots, or are themselves translated into other earth, not so drained of that particular matter out of which they are to be fed.

The older trees have some more supplies of fit matter than the younger, by means of the length of their

roots, which, when they have drained one spot of ground, usually are carried much farther into another, and reach a very great way; but at last they can reach no farther, and all fails, unless such a supply of manure, or the being removed into fresh earth, supply that nourishment they can no longer have where they stand. The gardeners, when they transplant trees, cut off these long roots; but, though they only do this to prevent the trouble of opening a larger hole than necessary for their reception, yet there is in nature this good reason for it, that they have, when brought to a fresh soil, no occasion for those long roots to draw nourishment from afar off, when there is enough of it every-where about them. What is to be learned from the whole of this, is, that the modern system is erroneous, which says, that water is the only thing that gives nourishment and increase to plants; since, if this was the case, there could be no need of manures, nor any need of altering the crop, in order to its succeeding, or of transplanting trees to make them thrive. It is plain that some sort of terrestrial matter, taken from among the soil, is what gives increase and bulk to plants; for where it is only water, the rain falling in all places alike, all would alike be at all times suited to produce all plants; and if the earth, according to Lord Bacon's system, served to no other purpose to plants and trees, but to keep their roots firm, and to defend them from these uses as another, and the same earth would do as well for over-heat, and over-cold, one earth would do as well for the same plant as a different earth. *Phil. Transf. N^o. 253.*

Brickish SOIL, a term used by our farmers to express a kind of hazely earth or land, with a reddish cast. It is frequent in Essex, and some other counties, and approaches to the nature of a loam. It has no stones in it, and does not bind after wet as clay does, but lets all the water in that comes, and has no slates in it; whereas all clays hold the water till the sun exhales, and, after rain, with a frost, moulder into dust.

These loams are an excellent mixture for other earths, being a happy medium between two extremes, uniting what is too loose, cooling what is too hot, and entertaining a moderate share of moisture.

The best produce of the brick earth is rye; if well dunged, it will bear white oats, turnips, barley, wheat, buck-wheat, and pease. The natural produce, in weeds, is broom, fern, quick-grass, and the like. If it be well dunged, it will produce large crops of clover, but it soon wears out of it, and should therefore be sowed mixed with rye-grass.

The best manure for these lands is chalk, mixed with coal ashes: marl makes a great improvement in them, and there is a stiff yellow kind of clay, that moulders with the frost, that answers the same purpose. Whatever amendment is bestowed upon this sort of land by dung, and other enriching things, that do not absolutely alter the nature of the earth, lasts but a little while. These lands bind very much after rain, and turn whiter; no frost will dissolve the clod, and if they are new ploughed up, and never so much rain comes on them, people may walk or ride over them almost as firm as over gravel. If they are not frequently ploughed, they are very subject to worms, which destroy the winter corn. They yield but poor crops in wet years; the weeds are generally very rank, and the wheat runs all into straw. Ploughing is a great improvement of them; they always grow well the year after it. These lands are to be ordered for corn in the same manner with the clay land, only as they are rank, and carry the crops much into straw, it is best to dung them on the etch crop, and to sow them with barley, and never to dung the fallows. Where the farmer has not an inclination to plow them, but keep them for grass, they should be mowed one year, and then kept short fed with sheep, which will in time sweeten them very much.

The red sandy lands in Northamptonshire are of this kind; they will not hold manure, so they plough but once for the year's crop, which is just before the sowing-time, and manure just before they plough it; for if they plough it oftener, and manure it sooner, they find a great quantity of the best mould washed away below the surface, and out of the reach of the roots of the corn.

In Oxfordshire they have a sort of red land, which they begin fallowing as soon in the year as they can, before the sun is too high: if it is moderately moist, when fallowed, they esteem it the better, but it should not be too wet. They seldom give it a second stirring, and they reckon that, if it is too fine and light, it runs to weeds. *Mortimer's Husbandry.*

SOIT *Fait Il Est Desiré*, be it done as it is desired, a form used when the king gives the royal assent to a private bill preferred in parliament.

SOL, or Sou, a French coin made up of copper mixed with a little silver. See the article EXCHANGE.

SOL, the sun, in astronomy, astrology, &c. See the article SUN.

SOL, in chemistry, is gold, thus called from an opinion that this metal is in a particular manner under the influence of the sun. See GOLD.

SOL, in heraldry, denotes or, the golden colour in the arms of sovereign princes.

SOLÆUS, or SOLARIS, in anatomy, one of the extensor muscles of the foot, rising from the upper and hinder part of the tibia and fibula. This is a large and fat muscle, thicker at the middle than at the edges, and is nearly of an oval figure.

SOLANUM, NIGHT-SHADE, in botany, a genus of plants, the corolla whereof consists of a single rotated petal; the fruit is a round smooth berry, punctuated at the top, and formed into two cells; the receptacle is fleshy and convex on both sides; and the seeds are numerous and roundish.

This genus comprehends the solanum, melongena, and lycopersicon of authors; or the common night-shade, the woody night-shade, the love-apple, and the mad-apple, &c.

Common night-shade is used to allay inflammations, to soften and relax the fibres which undergo too violent a tension; they apply the bruised herb to the piles, or bathe the part with the juice a little warmed: this juice is said to be proper in wounds where the blood is extravasated and grumous: it is also sudorific and diuretic, expelling gravel from the kidneys.

SOLAR, something belonging to the sun: thus the solar system is that system of the world wherein the heavenly bodies are made to revolve round the sun as the center of their motion.

Also the solar year is that consisting of three hundred and sixty-five days, five hours, and forty-nine minutes, in opposition to the lunar year, consisting of three hundred and fifty-four days.

For the solar month, solar cycle, solar eclipse, &c. see the articles MONTH, CYCLE, ECLIPSE, &c.

SOLDER, SODDER, or SODER, a metallic or mineral composition used in soldering or joining together other metals.

The word is formed from the French, *soudare*, and from the Latin, *solidare*, to strengthen.

Solders are made of gold, silver, copper, tin, bismuth, and lead; usually observing, that in the composition there be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of solder, viz. solder of eight, where to seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four, and solder of three. It is the mixture of copper in the solder that makes raised plate come always cheaper than flat. The solder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it and pouring a small quantity upon a stone; for if good, there will arise little bright shining stars therein. The solder for copper is made like that of the plumbers, only with copper and tin; for very nice works, instead of tin they sometimes use a quantity of silver. Solder for tin is made of two thirds of tin and one of lead; but where the work is any thing delicate, as in organ pipes, where the juncture is scarce discernible, it is made of one part of bismuth and three parts of pewter.

SOLDERING, among mechanics, the joining and fastening together two pieces of the same metal, or of two different metals, by the fusion and application of

some metallic composition on the extremities of the metals to be joined. See the last article.

To solder upon silver, brass or iron: take silver, five penny-weight; brass, four penny-weight; melt them together for soft solder, which runs soonest. Take silver, five penny-weight; copper, three penny-weight; melt them together for hard solder. Beat the solder thin, and lay it on the place to be soldered, which must be first fitted and bound together with wire, as occasion requires; then take borax in powder, and temper it like pap, and lay it upon the solder, letting it dry; then cover it with quick coals, and blow, and it will run immediately; take it presently out of the fire, and it is done. It is to be observed, that if any thing is to be soldered in two places, which cannot well be done at one time, you must first solder with the harder solder, and then with the soft; for if it be first done with the soft, it will unfold again before the other is soldered. Let it be observed, that if you would not have your solder run about the piece that is to be soldered, you must rub such places over with chalk.

In the soldering either of gold, silver, copper, and all the metals before-mentioned, there is generally used borax in powder, and sometimes rosin. As to iron, it is sufficient that it be heated red-hot, and the two extremities thus hammered together, by which means they will become incorporated into one another.

SOLDIER, a military man listed to serve a prince or state, in consideration of a certain daily pay.

The soldiers are properly the land forces of a kingdom or state; but in England it is against the ancient law to keep an army of soldiers in time of peace. Where any soldier that is lawfully retained shall depart from his colours without licence, he is declared to be guilty of felony by 18 Hen. VI. c. 9. and every soldier who either causes a mutiny or deserts the service, shall be punished with death or otherwise, as a court martial shall think fit. Also persons suspected of desertion, are to be apprehended by constables, who shall be allowed a reward of 20s. for every such deserter.

By the 4 Geo. I. c. 4. it is ordained, that no soldier shall be taken out of the service by any process at law, unless it be for some criminal matter, or where the debt he owes amounts to 10l. at the least, of which affidavit is to be made, &c. Soldiers must be quartered in inns and alehouses only, and not in private houses, without the consent of the owners, under certain penalties: and where victuallers refuse soldiers quartered on them, or constables receive any reward for excusing their neglect, they forfeit a sum not above 5l. nor under 30s. by 3 Geo. II. c. 2. A person enlisted for a soldier, within four days after, is to be carried before the next justice or chief magistrate of a town, and is to declare his assent that he listed voluntarily, &c. but if he then dissents thereto, on his returning the money received, and paying 20s. he may be discharged. In case any subject of Great Britain or Ireland shall list or enter himself, or procure any one to be enlisted a soldier to go beyond the seas, without leave obtained from his majesty, such person shall be punished as a felon by 8 and 9 Geo. II. There are acts annually made for punishing mutiny, &c. of soldiers and false musters, and for the better payment of the army and their quarters, &c.

SOLE, in the manege, a nail or sort of horn under a horse's foot, which is much more tender than the other horn that incompasses the foot, and by reason of its hardness is properly called the horn or hoof. A horse's shoe ought to be so set upon the hoof as not to bear upon the sole, for otherwise the sole would be hurt, and not only make the horse lame, but corrupt the flesh that separates it from the coffin-bone. To take out the sole, is to do it without touching the horn of the hoof; or if you take off the horn, you make a hoof-cast.

SOLECISM, *Solæcismus*, in grammar, a false manner of speaking, contrary to the use of language and the rules of grammar, either in respect of declension, conjugation, or syntax.

SOLEMN, *Solemnis*, something performed with much pomp, ceremony, and expence: thus we say, solemn feasts, solemn funerals, solemn games, &c.

In law, *solemn* signifies something authentic, or that is clothed in all its formalities.

SOLFAING, in music, the naming and pronouncing of the several notes of a song, by the syllables sol, fa, la, &c. in learning to sing it.

Mr. Malcolm observes, that the practice of solfaing, common as it is, is very useless and insignificant either as to the understanding or practising of music, yet exceedingly perplexing. The various applications of the several names according to the various signatures of the clef, are enough to perplex any learner: there being no less than seventy-two different ways of applying the names sol, fa, &c. to the lines and spaces of a particular system.

SOLID, in philosophy, a body whose minute parts are connected together, so as not to give way, or slip from each other upon the smallest impression.

In geometry, solid is the third species of magnitude, having three dimensions, viz. length, breadth, and depth.

A solid may be conceived to be formed by the revolution, or direct motion, of a superficies of any figure whatever, and is always terminated or contained under one or more planes or surfaces, as a surface is under one or more lines.

Solids are commonly divided into regular and irregular. The regular solids are those terminated by regular and equal planes, and are only five in number viz. the tetrahedron, which consists of four equal triangles; the cube or hexahedron, of six equal squares; the octahedron, of eight equal triangles; the dodecahedron, of twelve; and the icosihedron, of twenty equal triangles.

The irregular solids are almost infinite, comprehending all such as do not come under the definition of regular solids; as the sphere, cylinder, cone, parallelogram, prism, parallelopiped, &c.

SOLID of least Resistance. Sir Isaac Newton, in his Principia, shews, that if there be a curve figure, as DNFG (plate CXXI. fig. 10.) of such a nature, as that from any point, as N, taken in its circumference, a perpendicular NM be let fall on the axis AB; and if from a given point, as G, there be drawn the right line GR, parallel to a tangent to the curve in the point N, cutting the axis produced in R, and the proportion then be, as NM:GR :: GR³:4BG × GR; the solid generated by the revolution of this curve about its axis AB, when moved swiftly in a rare and elastic medium, will meet with less resistance from the medium, than any other circular solid whatever, of the same length and breadth.

SOLID ANGLE, is that formed by three or more planes meeting in a point, like the point of a diamond well cut.

SOLID BASTION. See BASTION.

SOLID NUMBERS, are those which arise from the multiplication of a plane number, by any other whatsoever; as 18 is a solid number made of 6 (which is plane) multiplied by 3; or of 9 multiplied by 2;

SOLID PROBLEM, in mathematics, is one which cannot be geometrically solved unless by the intersection of a circle and a conic section: or, by the intersection of two other conic sections, besides the circle.

As to describe an isosceles triangle on a given right line, whose angle at the base shall be triple to that at the vertex.

This will help to inscribe a regular heptagon in a given circle; and may be resolved by the intersection of a parabola, and a circle.

This problem also helps to inscribe a nonagon in a circle; and may be solved by the intersection of a parabola, and an hyperbola between its asymptotes, viz.

To describe an isosceles triangle, whose angle at the base shall be quadruple of that at the vertex.

And such a problem as this hath four solutions, and no more; because two conic sections can cut one another but in four points.

Line of SOLIDS, on the sector. See the article SECTOR.

SOLIDS, in anatomy, &c. denote the continent parts of the human body; being a congeries of pipes, or vessels, which contain a liquor.

The solid parts of the body, though equally composed of vessels, are different with regard to their consistence;

some being hard, and others soft. The hard, as the bones and cartilages, give firmness and attitude to the body, and sustain the other parts: the soft parts, either alone, or together with the hard, serve to execute the animal functions.

The solids are commonly divided into similar or simple; and dissimilar, compounded, or organic. The similar parts are the fibres, membranes, bones, cartilages, ligaments, muscles, tendons, aponeuroses, glands, arteries, veins, nerves, the secretory and excretory canals, and the common integuments.

The dissimilar are such as are composed of the former, as the viscera and other parts of the body, viz. the head, neck, thorax, abdomen, and extremities: every one of which is again subdivided into lesser portions.

SOLIDITY, *Soliditas*, in physics, a property of matter or body, whereby it excludes every other body from that place which itself possesses.

Among geometricians, the solidity of a body denotes the quantity or space contained in it, and is called also its solid content.

SOLIDITY, in architecture, is applied both to the consistence of the ground whereon the foundation of a building is laid; and to a mass of masonry of extraordinary thickness, without any cavity therein.

SOLILOQUY, *Soliloquium*, a reason or discourse which a man holds with himself.

Papias says, that soliloquy is properly a discourse by way of answer to a question that a man has proposed to himself.

Soliloquies are become very common on the modern stage, yet nothing can be more inartificial or more unnatural than an actor's making long speeches to himself to convey his intentions, &c. to the audience.

SOLITARY, *Solitarius*, something retired, or in private, remote from the company or commerce of others of the same species.

SOLITARIES, a denomination of nuns of St. Peter of Alcantara, instituted in the year 1676, the design of which is to imitate the severe penitent life of that saint: thus they are to keep a continual silence, never to open their mouths to any body but themselves; employ their time wholly in spiritual exercises, and leave the temporal concerns to a number of maids, who have a particular superior in a separate part of the monastery; they always go bare-footed, without sandals; gird themselves with a thick cord, and wear no linen.

SOLSTICE, in astronomy, that time when the sun is in one of the solstitial points; that is, when he is at his greatest distance from the equator, thus called, because he then appears to stand still, and not to change his distance from the equator for some time; an appearance owing to the obliquity of our sphere, and which those living under the equator are strangers to.

The solstices are two in each year, the æstival or summer solstice, and the hyemal or winter solstice: the summer solstice is when the sun seems to describe the tropic of Cancer, which is on the 22d of June, when he makes the longest day: the winter solstice is when the sun enters the first degree, or seems to describe the tropic of Capricorn, which is on the 22d of December, when he makes the shortest day.

This is to be understood as in our northern hemisphere; for in the southern, the sun's entrance into Capricorn makes the summer solstice, and that into Cancer the winter solstice.

The two points of the ecliptic, wherein the sun's greatest ascent above the equator, and his descent below it, are terminated, are called the solstitial points; and a circle, supposed to pass through the poles of the world and these points, is called the solstitial colure.

The summer solstitial point is in the beginning of the first degree of Cancer, and is called the æstival or summer point; and the winter solstitial point is in the beginning of the first degree of Capricorn, and is called the winter point. These two points are diametrically opposite to each other.

SOLVENT, the same with dissolvent. See the article DISSOLVENT.

SOLUTION, in pharmacy, considered as an operation, is the commixing solid bodies with fluids in such a manner

manner that, commensuating, they shall be thereby also converted to fluidity, and the whole rendered one equable similar fluid.

The intentional ends of solution are sometimes only the procuring a fluid form of the matter dissolved without any farther change either in that or the solvent; as in the solution of salts, gums, resins, &c. where the menstruum is to be considered only as a vehicle: at others, the producing new combinations of such bodies, as, when thus compounded, either acquire properties which they had not, while separate, or lose such as they then possessed, as in the instances of fixed alkaline or volatile salts dissolved in vinegar, to form the sal diureticus, or Mendereus's mixture or spirit as it is called; where the acid or alkaline qualities of the ingredients are lost, and a neutral salt, with peculiar qualities, is produced. Solution is also indispensably requisite in order to the crystallization of salts.

As the nature of solvents or menstrea, as well as the bodies required to be dissolved, are extremely various, the manner of effecting solutions is consequently different. In many cases a simple commixture, supported by frequently shaking the vessel, if small, or stirring the contents, if larger, is found sufficient: in others the aid either of a digestive or boiling heat is absolutely necessary. Sea salt, nitre, all the vitriolic salts, sal ammoniacum, allum, soluble tartar, sugar, vitriolic tartar, crude tartar, where a strong solution is not required, fixed alkaline and volatile salts, all the gums soluble in water, camphire, sal diureticus, nearly all the resins therein soluble, in spirit of wine, and metals in their proper menstrea, may be dissolved cold, though not with equal expedition, as when heat is employed.

Calces of metals and mercury in acid spirits; mercury sublimate in water; and several of the hardest gum resins are best dissolved in the heat of digestion.

Allum, Glauber's salts, vitriolate tartar, where the solution is not intended to be very weak; borax, and all other salts where a strong solution is demanded, and in singlases, require to be boiled.

Solution is much facilitated by the powdering such tenacious bodies as are friable, or slicing or rasping into small parts, such whose texture admit not of being powdered; and this is in some cases of such importance, that the operation is extremely tedious, if it be neglected.

In solutions of metals, earths, or salts in acid spirits, care should be taken that they be not mixed too hastily; otherwise the ebullition will occasion the mixtures to overflow the vessels, or, in some instances, an unmanageable heat and such noxious fumes will ensue, as give great embarrassment to the operator. The form of the vessels is not material in this operation, unless where digestion is required, in which cases the rules given for that operation are to be observed: but the substance of the containing vessel is to be regarded, lest from the action of the menstruum it may either be damaged or the medicine depraved.

Besides the solutions made by the adding fluids to bodies to be dissolved, there is another kind called deliquation, or solution per deliquium. It is performed by exposing the matter to the air, from which attracting water it collects in time a sufficient quantity to dissolve itself. Cellars, or other damp places, are the most proper for this purpose. But as the produce of this kind of solution is no other than may be obtained in the common way, by adding the same quantity of water as the matter by this means collects, it merits more to be totally rejected than improved. There are however two processes on this principle retained in the new college Pharmacopœia, under the names of *lixivium tartari*, and *lixivium martii*.

No phenomenon in nature is more universally known, than the solution of salts in common water; but the world has not yet attended to all that might be learned from the observations on it.

Mr. Lemery, who examined into this point with assiduity, has observed, 1. That the first effect of water upon a salt is the reducing it into an inexpressibly fine powder. 2. That it is merely the consequence of this pulverization carried greatly farther, that every particle of

salt which, while in larger molecularæ, subsided to the bottom of the water, according to the known laws of hydrostatics, becomes capable of being elevated and suspended in the water, though in itself greatly heavier than that fluid; that, while in a proper state of separation in this manner, they remain imperceptible in all the water, and when by certain accidents they again approach one another, they form concretions like their original ones, and again subside in that fluid, in which they floated while in form of this imperceptible powder.

In the solutions of salts, the same author observes, that all the particles of water do not serve to the same purpose; some officiating only in the keeping the saline particles suspended, others in the keeping them asunder, and, as barriers, preventing their reunion.

The quantity of water necessary to sustain the particles of all salts in solution, is the same; but the quantity required to keep those particles from joining again, is different, in regard to every salt. Hence, though a quantity of water, equal to the weight of the salt, be sufficient to the suspension of its particles, yet every salt requires its own appropriated quantity of water to keep it in a state of solution, that is, to keep its particles from cohering together again. In such salts, the particles of which are not subject to form hard concretions, such as the fixed salt of tartar, and the like, there requires no more water for a solution than is necessary to suspend the particles of the salt; but in those which readily form solid concretions, such as common salt, nitre, borax, and the rest, there requires a large quantity besides to act as a barrier.

The more the particles of any salt are disposed to reunite, the more water they require to keep them in a state of solution; and hence follows a very remarkable phenomenon, which is the solution of several salts successively in the same water: this is known to be possible, and the reason of the whole is this, that when a given salt, requiring a large quantity of water for its solution, is dissolved in that water; the greater part of that water, which in this solution serves only to the second purpose of keeping the particles of the salt asunder, is still at full liberty to act as water upon another salt that shall be thrown into it.

This, however, can be only the case in regard to salts which do not naturally ferment with one another, because the whole process is disturbed by such a fermentation, and, in consequence of it, there is a third salt formed, which is not the same with either of the two; and the consequence of the formation of this salt is the precipitation of the metallic or earthy matter, which was the base of one of the other salts.

Thus an alkaline salt, added to a solution of alum, or *saccharum saturni*, takes up the acid of either of these salts, and becomes, by its mixture with that acid, a new concrete salt, and at the same time throws down, in precipitation, the terrestrial base of the alum, and the metallic one of the salt of lead. To return to those salts which excite no fermentation with one another. In regard to these, when a quantity of water has dissolved as much as it can retain of one, it will readily take in and dissolve a second; and the particles of this, not fermenting with those of the salt first dissolved, will remain suspended, and the water which dissolves them, and which in the first solution served only as an intermedium to keep the particles of that salt asunder, serve as well to that purpose, now they are impregnated with this new salt, as they did before.

It is well known that salt of tartar does not ferment with salt-petre, nor does it take any thing from this salt, or at all alter by being mixed with it, which is quite different from the effect on mixing it, as before observed, with alum, or *saccharum saturni*; on this principle, and on the known property of salt of tartar being dissolved in a smaller quantity of water than any other salt; or, in other words, of water's dissolving more salt of tartar than any other salt, Mr. Lemery resolved, on the trial, whether water which had already dissolved as much nitre as it could contain, would not, on the addition of salt of tartar, dissolve a larger quantity of fresh nitre, than on the addition of sal armoniac, or any other

other salt: but what appeared very strange was, that after two days standing of a solution of nitre, with about a fourth part of the quantity of salt of tartar added, there was found a white powder at the bottom. The liquor, being examined on this, was found to be a lixivium of salt of tartar, and the powder, at the bottom, salt-petre.

On adding fresh quantities of salt of tartar, new precipitations were afterwards formed, and, in fine, all the salt-petre which had been dissolved was separated. The salt-petre being examined, by all trials proved true salt-petre, as pure and unmixed as when put in; and the liquor being evaporated, the salt of tartar was found equally pure. Salt of tartar tried afterwards in the same manner with solutions of other salts, with which it does not raise any fermentation, was found to have the same effect, precipitating all equally out of the solution.

In the common precipitations of salts, such as alum and sugar of lead, by means of an alkali, the alkali seizes upon the acid of those salts, and by that means effects the thing, and therefore itself becomes changed into another salt, and the precipitate, robbed of that acid, is no longer the salt it was, but merely its base: but here the salts, both alkali and neutral, remain the same they were before both pure and unmixed, and the whole process seems only one of them taking the place of the other.

The salts which are capable of successive solutions in the same water, and of remaining suspended together in it, must be all of the neutral kind; that is, they must be salts composed of acids, engaged in such manner in the pores of their bases, as to fill the whole, and leave no void spaces for the penetration of other acids. But this is by no means the case with salt of tartar, which, being wholly sponge-like in its structure, readily admits all sorts of acids, and ferments with them: and therefore is very capable of divesting other salts of that, on the presence of which their natural state, as salts of a particular kind, depends.

Every alkali salt is, as it were, an essential salt, in part decomposed; that is, it is the earthy part of such salt, the acid parts of which have been driven off by fire, and when there is only so much left, as may give the whole a saline form; for, if all the acids were to be driven off, the remainder would not be an alkali, nor yet a salt, but a mere simple earth; as is the case in the caput mortuum of spirit of nitre distilled by a retort, the residuum from this distillation being a mere dead earth, indissoluble in water, and altogether different from the fixed alkali produced by burning the same nitre with charcoal. What proves, also, that these alkalies are only the matrix of the compound salts divested of their acids, is, that if spirit of nitre be poured upon the alkali salt of nitre made with charcoal, true nitre is regenerated. *Mem. Acad. Par. 1724.*

SOLUTION, in algebra and geometry, is the answering a question, or the resolving any problem proposed. See **ALGEBRA** and **GEOMETRY**.

SOLUTION of Continuity, in surgery, is the separation of the natural cohesion of the solid parts of the body, by a wound.

SOLUTIVE, an appellation given to laxative and loosening medicines.

SOMNAMBULI, in medicine, persons who walk in their sleep, otherwise called noctambuli. See the article **NOCTAMBULI**.

SOMNIFEROUS, or **SOPORIFEROUS**. See the article **SOPORIFEROUS**.

SON, *Filius*, an appellation given to a male child, considered in the relation he bears to his parents.

SONATA, in music, a piece or composition wholly performed with instruments; and which is, with regard to instruments, what the cantata is with respect to voices.

SONG, in poetry, a little composition consisting of simple, easy, natural verses, set to a tune, in order to be sung.

SONG, in music, is applied, in general, to any single piece of music, whether contrived for a voice or instruments.

SONNA, a book of Mahometan traditions, wherein all the orthodox Mussulmen are required to believe.

SONNET, *Sonetto*, in poetry, a kind of composition properly contained in fourteen verses, viz. two stanzas or measures of four verses each, and two of three; the eight first verses being all in two rhymes.

The sonnet is of Italian origin, and Petrarch is allowed to be the father of it: it is held the most difficult and artful of all poetical compositions, as requiring the utmost accuracy and exactness. It is to end with some pretty ingenious thought: the close must be particularly beautiful, or the sonnet is naught.

SONNITES, among the Mahometans, an appellation given to the orthodox Mussulmen, or true believers; in opposition to the several heretical sects, particularly the Schiites, or followers of Ali.

The Sonnites are so called from their believing in the Sonna, or book of Mahometan traditions; which the Schiites reject as apocryphal. The Turks assume the name of Sonnites, in opposition to the Persians, who are Schiites. The former think it unlawful to detain as slaves any who are Sonnites, though taken in war: if any such are rebels, they must either be punished with death, or released. But this law is not observed by the Tartars, though they are Mahometans of the same sect with the Turks.

SOOT, *Fuligo*, a volatile matter, arising from wood, and other fuel, along with the smoke; or rather, it is the smoke itself, fixed and gathered on the sides of the chimney.

Wood-foot is of a shining black colour, a disagreeable smell, and an acrid, bitter, and nauseous taste; its chief use, for medicinal purposes, being in hysterical cases, in which it is sometimes exhibited in conjunction with the fetid gums.

The volatile salt and spirit of soot are, when sufficiently purified, not different in quality from those of animal substances; though some prefer them in nervous complaints, and particularly in epileptic cases. The tincture of soot is made thus: take of wood soot, two ounces; of asafœtida, one ounce; and proof spirit, two pints: digest and strain. It is good not only in hysterical cases, but also in epilepsies, and other nervous disorders.

Soot makes an excellent manure for cold lands that have been over-run with moss; but the soot of sea-coals is better for this purpose than that of wood. The dyers also make a considerable use of soot, for a dun colour.

SOPHI, or **SOFI**, a title given to the emperor of Persia; importing as much as wise, sage, or philosopher. There is no prince in the world whose authority is more absolute than that of the sophi of Persia.

SOPHISM, *σοφισμα*, in logic, &c. an argument which carries much of the appearance of truth, and yet leads into error.

There is some need of a particular description of these fallacious arguments, that we may with more ease and readiness detect and solve them:

1. The first sort of sophism is called *ignoratio elenchi*, or a mistake of the question. 2. The next sophism is called *petitio principii*, or a supposition of what is not granted. 3. That sort of fallacy which is called a circle, is very near a-kin to the *petitio principii*. 4. The next sort of sophism is called *non causa pro causa*, or the assignation of a false cause. 5. The next is called *fallacia accidentis*, or a sophism, wherein we pronounce concerning the nature and essential properties of any subject, according to something which is merely accidental to it. 6. The next sophism borders upon the former, and that is when we argue from that which is true, absolutely, simply, and abstracted from all circumstances; this is called, in the schools, a sophism *a dicto secundum quid ad dictum simpliciter*. This sort of sophism has also its reverse; as, when we argue from that which is true, simply, and absolutely, to prove the same thing true in all particular circumstances whatever. 7. The sophisms of composition and division come next to be mentioned. The sophism of composition is, when we infer any thing concerning ideas in a compound sense, which is only true in a divided sense. The sophism of division is, when we infer the same thing concerning

cerning ideas in a divided sense, which is only true in a compounded one. This sort of sophism is committed when the word *all* is taken in a collective and distributive sense, without a due distinction. It is the same fallacy, when the universal word *all*, or *no*, refers to species in one proposition, and to the individuals in another. 8. The last sort of sophisms arises from our abuse of the ambiguity of words, which is the largest and most extensive kind of fallacy; and, indeed, several of the former fallacies might be reduced to this head. When the words or phrases are plainly equivocal, they are called sophisms of equivocation. This sophism, as well as the foregoing, and all of the like nature, are solved by shewing the different senses of the words, terms, or phrases.

But, where such gross equivocations and ambiguities appear in arguments, there is little danger in imposing on ourselves or others; the greatest danger, and what we are perpetually exposed to, in reasoning, is, where the two senses or significations of one term are near a-kin, and not plainly distinguished; and yet are sufficiently different in their sense to lead us into great mistakes, if we are not watchful. And, indeed, the greatest part of controversies, in the sacred or civil life, arise from the different senses that are put upon words, and the different ideas conveyed by them.

There is, after all these, another sort of sophism, which is wont to be called an imperfect enumeration or a false induction, when, from a few experiments or observations, men infer general theorems and universal propositions.

SOPHIST, a person who frames sophisms; that is, uses subtle arguments, with intent to deceive those he would persuade or convince.

The word is framed from the Greek, *σοφιστης*, an impostor, or deceiver.

SOPHISTICATION is the adulterating any thing with what is not good.

This practice unhappily obtains too much among chemists, and others, who make up medicines for sale; and, in many cases, the cheat is carried on so artfully, as to prevent a discovery, even among persons of the most discerning faculties.

SOPORIFICS, medicines which have the faculty of procuring sleep.

The word is formed from the Latin, *Sopor*, sleep.

SORBON, or **SORBONNE**, the house or college of the faculty of theology at Paris; because the assemblies of the whole body are held in the house of the Sorbon.

SORITES, in rhetoric, a kind of argument, wherein a number of proportions are gradually and minutely laid together, and something inferred from the whole.

The word is formed from the Greek, *σωρος*, an heap.

SORRANCE-WATER, a name given by our farmers to a solution of vitriol and some other ingredients in vinegar, a medicine much esteemed in many of the diseases of horses: it is prepared in the following manner:

Take Roman vitriol and roach alum, of each an ounce and half, verdigrease an ounce, copperas two ounces: reduce all these to powder together, and put them into a two-quart bottle, into which pour a quart of the strongest and best wine-vinegar; this is to be set in *balneo marie*. The short way of doing which by the farrier is this: he puts a whisp of hay into the bottom of a kettle, and then tying some pieces of lead or iron about the neck of the bottle, to make it heavy enough to sink in water, it is set upon the hay so as to stand very upright; then three notches are cut length-wise in the cork to give passage to some of the vapours when the bottle is heated, that it may not burst. When every thing is thus prepared, so much cold water is to be put into the kettle, that the neck of the bottle may stand two or three inches above it; the kettle is then to be set over the fire, and the water is to be made to boil, and kept boiling about half an hour, the bottle being at times taken out, and thoroughly shaken. When the salts are thus thoroughly dissolved in the vinegar, the whole is to be kept for use.

The method in which they use it is this: take an earthen pan, which will hold about twelve quarts; let

this be filled with urine that has been made by sound, healthy, and young persons; the staler the urine is, the better it is for use, and indeed it ought always to stand, at least, three weeks before it is used. It is proper for the farrier, therefore, always to keep a quantity of this ready, and, when the water is to be used, half a pint of it is to be mixed with a quart of the urine, or if it be required stronger, more of the water is to be added: these are to be thoroughly mixed together, and the legs, or other affected part of the horse, bathed with it with soft rags twice a day.

The virtues of this water are highly extolled; it is said to cure the glanders in two or three times dressing; it is also a sovereign remedy for the mange, either dry or wet, and for the rat-tails, scratches, goured or swelled legs and heels; and it also cures horses, when the grease is fallen into their heels, as the farriers express it. The farcy is also said to be often cured by a long continuance in the use of it, purging the horse two or three times, at different distances of time, during the time of his being under cure by the water. They also find it a good cleanser and healer of foul ulcers, and that it prevents the breeding of proud flesh and worms in wounds, and drives away a flux of humours that were falling upon any part. They use it also in clefts and cracks of the heels, and in wind-galls, especially in the prevention of the last by its repellent qualities. The green water alone is an excellent remedy for fistulas, cankers, and the galled backs of horses; disposing such serrances, as they are called, not to fester, rot, and grow worse, as all greasy and oily medicines do, but cleansing them, and laying the way to a very sound and standing cure.

SOVEREIGN, supreme; the chief and highest being, the Almighty; a term, in strictness, only applicable to God.

SOVEREIGN, with regard to subjects, is applied to kings, and princes, who are supreme and independent, and whose authority is bounded only by the laws of God, of nature, and the fundamental laws of the state.

SOUL, *Anima*, a spirit adapted to an organised body.

Many of the philosophers allow of two and some of three kinds of souls, viz. a rational soul, which they hold to be divine and infused by the breath of God. Irrational, or sensitive soul, which man has in common with brutes, and which is formed out of the elements.

The philosophers are not agreed, as to the manner wherein the soul resides in the body. Some hold it equally diffused throughout every part thereof. Others say it influences and acts on every part of the body, though it has its principal residence in some particular part, called the sensory. This principal part Des Cartes maintains, is the pineal gland of the brain, where all the nerves terminate, &c.

Borri, a Milanese physician, in a letter to Bartholine, *De Ortu Cerebri & Usu medico*, asserts, that in the brain is found a certain very subtle fragrant juice, which is the principal seat or residence of the reasonable soul; and adds, that the subtilty and fineness of the soul depends on the temperature of this liquor, rather than on the structure of the brain, to which it is usually ascribed. This liquor, we conceive, must be the same with what is usually called the nervous juice, or animal spirits; the constitution of which is, doubtless, of great importance, with regard to the faculties of the soul.

Mr. Locke distinguishes two principal faculties or powers of the rational or human soul, viz. perception and willing.

To these, other philosophers add others, as sensation, liberty, memory, imagination, and habit.

The mystic divines distinguish two principal parts in the soul; the superior part, which comprehends the understanding and the will; and the inferior part, which comprehends imagination and sensation. Thus, say they, Jesus Christ was happy on the cross in his upper part, and suffered in his lower part. The lower part did not communicate to the upper either its troubles, or its failings; nor the upper to the lower its peace or beatitude. From this distinction, the Quietists take in hand to maintain, that whatever passes contrary to good morals, in the lower part of the soul, is not contrary to the purity of the

upper part, inasmuch as the will has no share therein.

As to the soul of brutes, the Cartesians, and some others, deny its existence, in the common sense of the word soul; that is, they strip it of all the properties or faculties of the human soul: and the Peripatetics, on the contrary, invest it with the greatest part of them.

In man, a particular agitation of the fibres of the brain is accompanied with a sensation of heat; and a certain flux of animal spirits towards the heart, and viscera, is followed by love or hatred.

Now, the Peripatetics maintain, that brutes feel the same heat, and the same passions, on the same occasions: that they have the same aversion for what incommodes them, and, in the general, are capable of all the passions and all the sensations we feel.

The Cartesians deny they have any perceptions or notices at all; that they feel any pain or pleasure; or love or hate any thing. The ground of their opinion is, that they allow of nothing in brutes, but what is material, and that they deny sensations and passions to be any properties of matter. Some of the Peripatetics, on the other hand, maintain matter, when subtilised, framed, ranged, and moved in a certain manner, to be capable of sensation and passion; that beasts may feel and perceive, by means of the animal spirits, which are matter thus modified; and that the human soul itself only becomes capable of sensation and passion, by means of the same animal spirits.

But we must own it very difficult to reconcile the idea we have of matter with what we have of thought; to conceive that matter figured in any manner, whether in a square, a sphere, or an oval, should be pleasure, pain, heat, colour, or smell; or to conceive that matter, however agitated, whether in a circle, a spiral, parabola or ellipsis, should be love, hatred, or joy, — surpasses our endeavours.

The maintainers of the contrary opinion urge that appearance of sense, of fear, caution, love for their young, admirable sagacity, both for their own preservation and that of their species, visible through the whole brute creation. And it is true, all the actions of beasts plainly express an understanding; for every thing that is regular, expresses it; even a machine or watch expresses it: and a plant much more, the radicle of the seed turning downwards, and the stem upwards, whatever situation the seed is sown in: the young plant, knitting from space to space, to strengthen it; its putting forth prickles, &c. to defend it, &c. mark a great understanding. All the motions of plants and brutes plainly discover an intelligence; but the intelligence does not reside in the matter thereof: it is as distinct from the beast or plant, as that which ranged the wheels of the watch, is distinct from the watch itself.

For, in effect, this intelligence appears infinitely great, infinitely wise, infinitely powerful; and the same which formed us in our mother's womb, which gave us our growth, &c. Thus, in brutes, there is not either understanding or soul, in the sense we generally use the word: they eat without pleasure, cry without pain, grow without knowing it. They fear nothing; know nothing; and if they act in such manner as shews understanding, it is because God, having made them, to preserve them, has formed their bodies so as to avoid whatever might hurt them, mechanically.

Otherwise it might be said, that there is more understanding in the vilest insect, nay, in the smallest grain, than in the most knowing of men; for it is evident, either of them contains more parts, and produces more regular motions and actions, than we are capable of understanding. Thus does the great F. Malebranche argue against the souls of brutes.

SOUND, *Sonus*, a perception of the soul communicated by means of the ear; or the effect of a collision of bodies, and a tremulous motion consequent thereon, communicated thence to the circumambient fluid, and propagated through it to the organ of hearing.

We know by the experiment of the bell in the exhausted receiver, that sound has a necessary dependence on the air; and if we reflect on the nature of the parti-

cles of a sonorous body, and those of air, we shall find that sound is nothing but the propagation of the tremors, and the vibrations of the former impressed on the latter, to the tympanum or drum of the ear, by the action of whose membrane they are communicated to the internal cavities of the ear, where the auditory nerve receives the impression, and excites the sensation, in the common sensory, in the brain.

For the parts of a sonorous body, being put in motion by percussion, vibrate forwards and backwards, through very small spaces, by their elastic quality. In this action, they affect the particles of air contiguous to them, and compel them, upon the first impulse, to move forwards also; and these propel the next, and so on to a very considerable distance, according to the intensity of the percussive force. By this means, the particles of air are compressed nearer together, than in their natural state.

But when the particles of the sonorous body make the second part of the vibration, by returning back again, the particles of air, also, by their repulsive power, repel each other toward their proper places, and thus again expand themselves.

Now, since motion, once generated in elastic bodies, continues some time before it can be destroyed by the resistance and counter-action of contiguous bodies, it follows, that the particles of the sonorous body, and, consequently, those of the adjacent air, have, for some time, a reciprocal vibratory motion, by going forwards and backwards, through very small spaces, in indefinitely small particles of time; which motion gradually decreases, till it be totally destroyed.

Let *A B C* (plate CXXII. *fig. 1.*) be an elastic string, or chord, fixed in the points *A* and *C*, and drawn out of its natural right lined situation *A B C*.

Such a chord, in its state of tension, will, when let go, return, by its natural resort, not only to its natural situation *A D C*, but with the motion it there has will go on to *E*, so that *D E* is nearly equal to *B D*; and from thence it will return again nearly to *B*, which motion from *B* towards *E*, and from *E* towards *B*, will be reciprocated a great number of times before the chord will come to a state of rest; and each motion through the space *B E* is called the vibration of the chord.

When the chord begins its motion at first from *B*, it strikes the particles of air contiguous to it in *B*, and that will, by its approach towards the next, affect it by means of the repulsive power, which keeps them all at equal distances from each other, and so on through such a number of particles as can receive the motion, whilst the string moves from *B* to *D*. Let *A, B, C, D, E, F, G*, (*fig. 2.*) represent such a series of particles of air at an equal distance, and the first particle *A*, contiguous to the middle joint *B*, of such a string, and agitated by it in its motion.

The string beginning to move, all the particles *A, B, C*, will begin to move forwards also; and, since this motion is propagated in time, let *E* be the remotest particle moved, while the chord is moving from *B* to *D*, during which time the chord is going from *B* to *D*; therefore the distance *A B* will be less in *B C*, and this less than *C D*, and that less than *D E*, and the distance *E F* will begin to be lessened, when the string is arrived at the site *A B C*, and the particles *A, B, C, D, E, F*, &c. will have the arrangement represented in the second line. But now the chord, having acquired the situation *A D C*, will be no farther accelerated, but on the contrary retarded, as it will now go on from *D* to *E*; the effect of which, upon the particles of air before it, will be as follows: they will all go on forwards till the chord comes to *E*, and the particle *A* to its situation in the third line; but since the force upon *A* begins to abate, as the string begins to move from *D*, the elastic force now between *A* and *B* will, by acting both ways, continue to accelerate the motion of *B*, and retard that of *A*. Thus the distance *B C* will still diminish, till *B* comes to lie equidistant between *A* and *C*, and *C* will be accelerated till it be equidistant between *B* and *D*, and so on. So that, as the acceleration is continued forwards, the distances will diminish towards *F*; and, by the time the chord is arrived at *E*, the particles *E E* will be at their nearest

nearest distance. And, since the motion of A is continually retarded, it will lose what before it had gained in the same time, and will therefore now be at the same distance from B, as at first nearly. So that the particle from A to G will have the situations as represented in the third line.

The chord now returning from E to D gives liberty to the repulsive power between A and B to separate them to a greater distance than in their natural state, and which they at present have. By this means all the other intervals B C, C D, D E, E F, will increase, and become successively greater than the natural distance; but that excess will be lesser in each, till you come to F G, which will be equal to the natural distance at present between A and B. The motion at the same time continuing in all the particles from H to N, they will all move forwards, and the present contracted interval between H and I will succeed between all the rest, till it arrives at the particle N, when the interval M N will be the same as at present is M T. And those particles beyond N to S will, by the preceding ones, be put into the same respective distances, but in an inverse order, as those have between G and N. And the whole series, now the string is at D, will have the intervals of the particles resembling those in the fourth line.

The chord not stopping at the situation A C D, but going on to A B C, with a retarded motion, the velocity of the contiguous particle A will also be retarded, and becomes less than that of B; upon which, the distance between them will be lessened, and the more so, as the string approaches to B. Hence all the intervals, now dilated beyond their natural state, will, by degrees, contract; but gradually slower, till you come to T, where the present largest interval between A and B will be found between F and G, and that between A and B will have acquired its natural extent, when the chord is arrived at B. Then, likewise, the particles from G to N, will acquire the same situation as those now have between A and G; and from N to S, the same as now is seen between G and N; and from S forwards the same as is now before the particle N, the point S being now the middle point of condensation; all which is clearly seen in the fifth line of the figure. Thus the condensation which begins at A, by the first parts of the vibration, was propagated to G by the second, from thence to N by the third, and, lastly, to S by the fourth part of the whole motion of the string, in going and returning; and this extent of air, thus agitated by the chord in going and returning, is called by Sir Isaac Newton a wave, or pulse of air. In which wave the particles from A to N are in a dilated state, and from N to X in a contracted or condensed state; which two parts of the wave answer to the concave and convex, or low and high part of a watery wave.

As the chord goes on to make another vibration, it will not only continue to agitate the air at present in motion, but will spread the pulsation of the air as much farther, and by the same degrees as before; and the like will happen after a very complete vibration of the string. Thus the air being a fluid body, and the impression made on any one part affecting all the particles alike around it, it is plain those pulses will be propagated in every direction all around in concentric aerial shells, or spherical waves of air.

That the motion of the pulses in an elastic medium is analogous to that of the waves generated in the surface of stagnant water, is evident, when we consider that the condensation of the parts of the elastic medium is in lieu of the elevation of the water; the elastic force effects the same in the medium, as gravity does in the water, and the densest part of the pulses corresponds to the highest part of the waves.

Let A B C (*fig. 3.*) represent the sonorous body; by the tremulous motion of its parts, it will agitate the air contiguous to every point, as A, where it will be condensed to a certain small distance, and make a pulse or wave of air, in the manner as has been already shewn. The first wave or pulse will, by its elastic power in expanding itself, produce a second, that a third, and so on till the impressed motion be diffused through too large a quantity of air, to be any longer sensible.

The quantity of motion, produced by each tremor of the sonorous body, being communicated successively to large portions of air, the part thereof which each particle will acquire will constantly decrease. This decrement of the motion will be as the increment of the number of particles, which is as the superficies of the spherical shell; and since all superficies are as the squares of their diameters, or semi-diameters, therefore the force in the particles of the wave or shell at D is to that in the particles of the shell at T as $A F^2$ to $A D^2$, that is, the force of sound decreases as the squares of the distances increase.

It is plain the distance to which sounds may be heard, will be proportional to the magnitude or intensity of the stroke made on the tremulous body emitting the sound; for, the greater that stroke is, the greater will be the agitation of the parts of the sonorous body, and, of course, the greater will be the force with which they will strike the particles of air. Lastly, the greater the force is upon the air, the more closely will it be condensed and expanded; hence the greater will be the stroke at any given distance on the drum of the ear, and, consequently, the greater will be the distance at which the agitation of the air will be sensible.

The experiments are numerous by which it has been found, that sound is audible to the distance of 50, 60, or 80 miles, but Dr. Hearne, physician to the king of Sweden, tells us, that at the bombardment of Holmia, in the year 1658, the sound was heard 30 Swedish miles, which make 180 of ours. And in the fight between England and Holland, in the year 1672, the noise of the guns was heard even in Wales, which cannot be less than 200 miles.

Since the atmosphere consists not of pure air, but has a mixture of vapours of different elasticity and tone, these vapours will not participate of the motion of pure air, by which sound is propagated; in like manner, as an elastic string struck will not move another very near it, unless it be under the same degree of tension, and of the same tone. Therefore, the quantity of air, producing sound, must be diminished in proportion to the quantity of vapour in a given space; in which Sir Isaac Newton supposes the air is to the vapour as ten to one. Whence the air and vapour together, in a given space, are to the pure air as eleven to ten.

But the velocity of the pulses will increase in the subduplicate ratio of the diminished quantity of matter, that is, in the subduplicate ratio of eleven to ten, or in the entire ratio of twenty-one to twenty; therefore, if we say, as 20 : 21 : 1088 : 1142 : whence the real velocity of sound, thus investigated, from the nature of elastic air, by our great author, is at length found to be at the rate of 1142 feet per second.

The truth and accuracy of this noble theory have been sufficiently confirmed by experiments, particularly those made by the late Rev. Dr. Derham, of which we shall give some account, but will first lay before the reader a view of the different estimates made of the velocity of sound by several eminent philosophers, as in the table following :

As no man ever had a better opportunity, so none could improve it with greater diligence, assiduity, and accuracy, in determining and settling the various phenomena of sounds, than the so often celebrated author last mentioned. He proved by experiments made with the strokes of a hammer, and the explosion of a gun at the same time, at the distance of a mile, that the velocity of sounds produced from different bodies was the same, or came to his ear in the same time.

That

That the motion of sound was equable and uniform, or that it passed through spaces proportional to the times, he found by various experiments made by the explosion of guns, at different distances, as appears by the following table which he has given us, where the first column shews the places at which the guns were fired; the second the number of vibrations of an half-second pendulum; the third the distance of places in miles and decimal parts, as measured by trigonometry; the fourth the distances measured by the velocity of sounds, admitting it to be at the rate of one mile every $9\frac{1}{4}$ half-seconds.

The great exactness of measuring distances by sounds appears from the above table, as well as the equability of the motion; but, to render this matter still more certain and indisputable, the doctor took a journey to Foulness-sands, on the coast of Essex, which form a smooth large plain for miles. On this plain he measured six miles in a right line, and, causing a gun to be fired at the end of each mile, he found that his former observations were very just and true, and that sound passed the first mile in $9\frac{1}{4}$ half-seconds, two miles in $18\frac{1}{2}$, three miles in $27\frac{3}{4}$, and so on to the end of the six.

The Academia del Cimento made experiments of this sort, from which they concluded, that the velocity of sounds was so far equable, as not to be accelerated or retarded by conspiring or adverse winds; but in this they led themselves and many others into a very great mistake, which was owing to their firing of guns at too near a distance; for in great distances the difference is sensible.

SOUND, in music, denotes a quality of the several agitations of the air, considered so that their disposition, measure, &c. may produce music or harmony.

SOUND, in geography, implies a streight, or inlet of the sea, between two head-lands.

The famous streight which joins the German ocean to the Baltic, is called, by way of eminence, the Sound.

SOUND-BOARD, the principal part of an organ, and that which makes the whole machine play.

The sound-board, or summer, is a reservoir into which the wind, drawn in by the bellows, is conducted by a port vent, and hence distributed into the pipes placed over the holes of the upper part. The wind enters them by valves, which open by pressing upon the stops or keys, after drawing the registers which prevent the air from going into any of the other pipes, but those it is required in.

SOUNDING, in navigation, the act of trying the depth of the water, and the quality of the bottom, by a line and plummet, or other artifice.

The sounding-line is the thickest and shortest, as not exceeding twenty fathoms in length; and marked at two, three, and four fathoms, with a piece of black leather between the strands; and at five with a piece of white leather. The sounding line may be used when the ship is under sail, which the deep sea-line cannot. The plummet is usually in the form of a nine-pin, and weighs eighteen pounds, the end of which is frequently greased, to know whether the ground is sandy or rocky. Near banks, shores, &c. they sound continually.

SOUR Land, in agriculture, a term used by the farmers to express a cold, and somewhat wet clayey soil.

This must have its tilth according to its state and condition, when they set about it. If it have a strong swarth upon it, then they give it a fallow, by turning it up, when the sun is in Cancer; this they call a scalding fallow, and esteem it of great use, because it kills the grass

roots, and makes the land fine; but, if it be light, and have but a thin swarth, they leave it for a cooler tillage, and plow it early in the year, when their clay is fallowed. Pigeon's dung and malt dust are the most proper manures for this soil. The malt dust is to be sown with the winter corn, and plowed in with it, for then it lies warm at the roots of the corn all winter.

SOW, in the iron-works, the name of the block, or lump of metal, they work at once in the iron-furnace. The size of these sows of iron is very different, even from the same workmen, and the same furnace. These furnaces having sandstone for their hearths and sides, up to the height of a yard, and the rest being made of brick, the hearth, by the force of the fire, is continually growing wider; so that, if it at first contains as much metal as will make a sow of six or seven hundred weight, at last it will contain as much as will make a sow of two thousand weight.

SOWING. One very great article, in sowing to advantage, is to know exactly at what depth the seed may be planted, without danger of burying it. Seed is said to be buried, when it is laid at a depth below what it is able to come up at. Different sorts of seeds come up at different depths, some six inches, or more; and others will not bear to be buried at more than half an inch. The way to come at an accurate knowledge of the depth at which every seed will come up best from the sowing, is by making gages in the following manner: saw off twelve sticks of about three inches diameter, bore a hole in the end of each stick, and drive into each a taper peg; let the peg in the first stick be half an inch long, the next an inch, and so on, every peg being half an inch longer than the other, till the last is six inches long: then in that sort of ground, in which you intend to plant, make a row of twenty holes with the half-inch gage, put therein twenty good seeds, cover them up, and then stick the gage at the end of that row. Proceed in the same manner with the eleven other gages, making the holes in the same row all with the same gage, and sticking it at the end of the row: when the seeds begin to appear, it will be easy to see at what depth they come up best, by observing the most flourishing row, and taking up the gage at the end, and seeing what is its length.

By this means we not only know what is the depth in that sort of ground, at which this sort of seed will come up best, but also we are able to judge of the nature of the seed; for by observing how many of the twenty seeds that were sown come up, and how many fail, it is easy to calculate how much bad seed there is among any given quantity, and to allow properly for it in the sowing, that the field may be neither overstocked with plants, nor too bare of them. The farmer often sustains great losses by sowing bad seed, or by burying good seed, and both might be effectually prevented, by making these easy trials. One caution is to be observed in this, that it is not proper to sow the seeds of all plants at the greatest depths at which they will come up, because in wheat, and some other grain, a moist ground will rot the roots at this depth. Experience alone, added to these rules, can perfectly instruct the farmer in the certain way of succeeding; the nature of the land, the manner how it is laid, either flat or in ridges, and the season of planting, must all be considered.

The quantity of seed is to be different also, according to the manner of the sowing. The proper quantity to be drilled into an acre, is much less than must be sown in the common way; not because the hoeing will not maintain as many plants as the other way, for, on the contrary, it will maintain many more; but the difference is upon many other accounts, as that it is impossible to sow it so evenly by hand as the drill will do. For let the hand spread it never so exactly, which yet is difficult enough to do with some seeds in windy weather, yet the unevenness of the ground will alter the situation of the seeds, the greatest part of them rebounding in the holes, and the lowest places, or else the harrows, in covering, drawing them down thither: so that these low places may have ten times too much seed, and the highest may have much too little, or even none of it: and this inequality lessens in effect the quantity of the seed, because fifty seeds, in the room of one, will not produce so much as

one will do; and where they are too thick, without being in these clusters, they cannot well be nourished, their roots not spreading to near their natural extent, for want of hoeing to open the earth, and give them way. In the common way of sowing, some of the seeds are buried out of all hope of ever coming up again, and some others are left naked upon the surface, where they become the food of birds, and of vermin: as so many must, therefore, perish in the common way of sowing, and so few can be lost in the way by drilling; there is plain reason why the seed, necessary to sow any given quantity of ground, should be much less for the drill-way, than for the other.

The farmers, in general, know nothing of the proper depth at which they should sow their seed, nor of the difference in quantity that is to be observed in different circumstances; they allow the same quantity to an acre of rough ground, as they do to an acre of fine, and forget that what is too little for one, may yet be too much for the other; it is all mere chance-work, and they put their confidence in good ground, and a large quantity of dung to cover their errors.

The farmers in Wiltshire allow more corn for the sowing, than in any other part of England; they use sometimes eight bushels of barley to an acre, so that, if it produce four quarters for an acre, there is but four grains for one increase. This is sown on land plowed once, and double dunged, the seed only harrowed into the hard and stale ground, so that it is very probable that not so much as two bushels out of the eight take place, or come to any thing. Sometimes, in a very dry season, an acre scarce produces four bushels at the harvest.

Instead of all this uncertainty and loss in the common way, in drilling all the seed lies just at the same depth, not one grain of it being placed deeper or shallower than the rest. As none of the seeds, therefore, can be lost by being buried, or by being exposed on the surface to vermin, no allowance is to be made for these accidents; all that is to be allowed for in the sowing, is the mischief that may happen from the worm, the frost, or the like unavoidable accidents common to all seeds.

When a man has (by the use of the gages and the growth of the seeds planted in the rows marked by them) proved the goodness of the seed, and found the depth it is to be planted at, he is to calculate what number of seeds a bushel, or any other weight or measure, contains; for one bushel, or one pound of small seed, may contain double the number of seeds of a bushel, or a pound of large seed of the same species. This calculation is made by weighing an ounce, and then calculating the number of seeds this ounce is composed of; then weighing a bushel, and multiplying the number of seeds in an ounce by the number of ounces in the bushel, and the product will give the number of seeds in the bushel with sufficient exactness.

When this is known, the seeds are to be proportioned by the Rule of Three to the square feet in an acre; or else it may be done, by dividing the seeds of the bushel by the square feet in an acre, and the quotient will give the number of seeds for every foot. Then the farmer is to consider how near he intends to plant the rows, and whether single, double, treble, or quadruple; for the more numerous the rows are, the more seed will be required. The narrow spaces between double, triple, or quadruple rows, suppose seven inches; the double having one, the treble two, and the quadruple three, are called partitions. The wide space, suppose of five feet, between any two of these double, treble, or quadruple rows, is called an interval. Examine next what is the produce of one middle-sized plant of the annual, but the produce of the best and largest of the perennial sort, because that, by hoeing, will be brought to its utmost perfection; proportion the seed of both to the reasonable product, and, when it is worth while, adjust the plants to their competent number with the hand-hoe after they are up, and plant perennials generally in single rows. Lastly, plant some rows of the annual thicker than others, which will soon give experience, preferable to all the rules in the world, for the quantity of seed necessary for the drilling. The distances of the rows is one extremely material point in the obtaining a good crop; but as a much

larger distance is to be allowed in these, than common practice has been used to, it is very difficult to persuade the farmer to venture a trial at such distances as he may have experience from. There is a method of planting the rows by the drill at very near distances, and in this work one horse may draw a drill with eleven shares, making the rows at three inches and a half distance from each other, and at the same time sowing in them three different sorts of seeds, which do not mix, and these at different depths. Thus the barley-rows may be seven inches asunder; and the barley four inches deep; a little more than three inches above that, in the same channels, clover-seed; and, between every two of these rows, a row of saintfoin seed covered half an inch deep.

Mr. Tull, who tried this method, obtained the first year a very good crop of barley; the next year, two crops of broad clover, where that was sown; and where the hop-clover was sown, a mixture of that and saintfoin, and every year afterwards a crop of saintfoin. But the same gentleman was afterwards so fully convinced of the folly of these, or any other mixed crops, and of sowing with these narrow, that he never practised it afterwards.

Every row of vegetables, to be horse-hoed, ought to have an empty space, or interval of thirty inches, on one side of it at least, and of near five feet in all sorts of corn: this will seem a monstrous allowance to those who have not experienced the good effects of it, but all who have will readily come into the practice of it ever afterwards. The line of corn is called one row, though it be double, triple, or quadruple, because, when four of these rows grow up in the spring, they unite, and seem to be all one row. Wide intervals are necessary for perfect horse-hoeing, and the largest vegetables have generally the greatest benefit by them, though small plants may have considerable benefit from much narrower intervals than those of five feet.

In hand-hoeing there is always less seed, fewer plants, and a greater crop, *cæteris paribus*, than in the common sowing; yet, there the rows must be much nearer than in horse-hoeing, because, as the hand moves many times less earth than the horse, the roots will be sent out in a like smaller proportion; and if the spaces, or intervals, where the broad hoe only scratches a little of the surface, should be wide, they would be so hard and stale underneath, that the roots of the perennial plants would be a great while in running through them, and the roots of annual plants would not be able to do it at all.

The advantage of the horse-hoeing is principally owing to the depth to which it stirs the ground, and familiar instances have proved, that the stirring it to a like depth, by whatever instrument, is of the utmost advantage to whatever plants are set in the place.

A poor fellow in Wiltshire was observed to have always his cabbages much larger and finer than his neighbours, though his ground was no better, and he could afford less dung; but the reason was, that instead of clearing away the weeds between them with a hand-hoe, he used to dig between them with a spade, which goes as deep as a horse-hoe, and comes the nearest answering its purposes of any instrument whatever. *Tull's Horse-hoeing Husbandry.*

SPA, a town in the bishopric of Liege, in Germany, famous for its mineral waters. Those of the Pouhon spring in Spa are preferred, by our chief physicians, to any others in or near the county of Liege.

The contents of this water, by means of which it is able to do such great things in many chronical cases, are understood by the following experiments and observations.

First, when the Spa-water is carried to any distant place, though ever so well stopped down, they always, after a time, will precipitate a small quantity of a yellow ochreous earth.

Secondly, if a single grain of galls be put into an ounce of Spa-water, it tinges the whole with a beautiful purple; but, if the water be heated before the galls are put in, there will not be the least change of colour produced in it.

Thirdly, mixed with milk, they do not coagulate it; but, when mixed with wine, they make a great ebullition.

tion, and throw up a large quantity of air-bubbles with a peculiarly pleasing smell.

Fourthly, the waters drank at the spring cause a sort of drunkenness, but it does not last above a quarter of an hour.

Fifthly, a small phial, being filled up to a certain height with Spa-water, and afterwards exactly to the same height with pure distilled water, and weighed, when filled with each, in a nice balance, was found, when the Spa-water was in it, to weigh three ounces, four drachms, and forty grains: and with the other three ounces four drachms and forty-one grains; so that the Spa-water, notwithstanding its mineral particles, is somewhat lighter than the purest common water.

Sixthly, and finally, a pint of the Spa-water evaporated over a very gentle fire, leaves behind only a grain and half of a white powder.

Hence, it appears, that the Spa-waters are the lightest and most subtile of all the mineral waters; and the small quantity of earth, and large portion of subtile mineral spirit they contain, bespeak their possessing the most exalted virtues of all the mineral waters.

One very remarkable virtue of this water is, that it greatly relieves in all disorders of the kidneys, ureters, and bladder, whether occasioned by stone, gravel, or ulcerations. It possesses, besides, all the virtues of the other mineral waters, and is of the greatest service in edulcorating sharp, and dividing viscous humours, and removing all diseases arising from these causes, by disposing them to pass off by the proper emunctories.

SPACE, *Spatium*, is defined by Mr. Locke, to be a simple idea which we attain both by our sight and touch; the modes of which are distance, capacity, extension, duration, &c.

Space, considered barely in length, between two bodies, is the same idea which we have of distance. If it be considered in length, breadth, and thickness, it is properly called capacity; when considered between the extremities of matter which fills the capacity of space, with something solid, tangible, and moveable, it is then called extension; so that extension is an idea belonging to a body, but space, it is plain, may be conceived without it. Each different distance is a different modification of space, and each idea of any different space is a simple mode of this idea: such are an inch, foot, yard, &c. which are the ideas of certain stated lengths, which men settle in their minds for the use, and by the custom of measuring. When these ideas are made familiar to mens thoughts, they can repeat them as often as they will, without joining to them the idea of body, and frame to themselves the ideas of feet, yards, or fathoms, beyond the utmost bounds of all bodies, and by adding these still one to another, enlarge their idea of space as much as they please. From this power of repeating any idea of distance without ever coming to an end, we come by the idea of immensity.

Another modification of space is taken from the relation of the termination of the parts of extension, or circumscribed space, amongst themselves; and this is what we call figure. This, the touch discovers in sensible bodies, whose extremities come within our reach; and the eye takes, both from bodies and colours, whose boundaries are within its view; where observing how the extremities terminate, either in straight lines, which meet at discernible angles; or in crooked ones, wherein no angles can be perceived; by considering these as they relate to one another in all parts of the extremities of any body or space, it has that idea we call figure, which affords to the mind infinite variety.

Another mode belonging to this head is, that of place.

There is another mode of space, the idea of which we get from the fleeting and perpetually perishing parts of succession, which we call duration.

Space is usually divided into absolute and relative. Absolute space is that considered in its own nature, without regard to any thing external, which always remains the same, and is infinite and immoveable.

Relative space, is that moveable dimension, or measure of the former, which our senses define by its posi-

tions to bodies within it, and this is the vulgar use for immoveable space.

Relative space in magnitude and figure, is always the same with absolute; but it is not necessary it should be so numerically; as if you suppose a ship to be, indeed, in absolute rest, then the places of all things within her will be the same, absolutely and relatively, and nothing will change its place: but suppose the ship under sail or in motion, and she will continually pass through new parts of absolute space; but all things on board, considered relatively in respect to the ship, may be, notwithstanding, in the same places, or have the same situation and position in regard to one another.

Proper and absolute motion is defined to be the application of a body to different parts of absolute, that is, infinite and immoveable space. The Cartesians, who maintain extension the essence of matter, assert, that the space any body takes up is the same thing with the body itself; and that there is no such thing as mere space void of all matter in the universe.

SPACE, in geometry, denotes the area of any figure, or that which fills the interval or distance between the lines that terminate it.

SPACE, in mechanics, the line a moveable body, considered as a point, is conceived to describe by its motion.

SPADE, an instrument for digging up the ground, the handle or shaft whereof is about three feet long; the head is all of iron; the upper part being flat for the workman to set his foot on, to force it into the ground; the length of the head is about a foot or fifteen inches, and the breadth six or eight.

SPAGIRIC ART, *Ars Spagirica*, a name given by authors to that species of chemistry which works on the metals, and is employed in the search of the philosopher's stone.

SPAHS, horsemen in the Ottoman army, chiefly raised in Asia. The great strength of the grand seignior's army consists in the janizaries, who are the foot, and the spahi's, who are the horse.

SPAIN, including Portugal, is a large peninsula of Europe, lying between 10° west and 3° east longitude, and between 36° and 44° north latitude, being about seven hundred miles in length from east to west, and about five hundred in breadth from north to south: it is bounded by the bay of Biscay, on the north; by the Pyrenean mountains, which separate it from France, on the north-east; by the Mediterranean-sea, on the south-east; and by the Atlantic ocean, on the west. See PORTUGAL.

SPAN, a measure taken from the space between the thumb's end and the tip of the little finger, when both are stretched out.

The span is estimated at three hand's breadths, or nine inches.

SPAR, in natural history, a shining stony substance, generally, though improperly, supposed to be compounded of crystal, incorporated with some mineral, earthy, stony, or metallic matter; frequently found in caves and grotto's, and in the clefts of rocks, lead mines, &c.

Spar is naturally pellucid, and is found in almost an infinite variety of forms; in some of which it retains its transparency and purity, in others it is more or less debased by an admixture of earth, and grows, accordingly, less and less clear, till, from the marbly hue of some of the moderately debased kinds, it sinks in some to a mere earthy appearance. The genuine and distinguishing characters of spar, in whatever form it occurs, are these; it will not produce fire when struck against a steel, it ferments very briskly with aqua fortis, and, when pure, is totally dissolved by it, and is very readily calcined in a small fire.

Spars are defined to be fossils not inflammable, nor soluble in water. When pure, pellucid and colourless, and emulating the appearance of crystal, but wanting its distinguishing characters; composed of plane and equal plates, not flexible nor elastic; not giving fire with steel, readily calcining in a small fire, and fermenting violently with acids, and wholly soluble in them.

The

The observation, that spar is continually formed at this time in caves and grottoes under ground, has given birth to many different conjectures, as to the origin of that substance.

We have accounts from Switzerland, and other places, that the snow, by long lying on the earth, and being subject to repeated freezing, is at length hardened into spar: this is much of the nature of that opinion of the ancients concerning crystal, that it was water frozen by severe colds to a sort of ice, much harder than the common kind; both are equally erroneous and absurd. But more rational conjectures, as to its origin, are, that it is produced either by effluvia alone, or by the joint force of effluvia issuing up from the depths of the earth, and mixing with water ouzing out of the rocks into their cracks and cavities, or by the same water or effluvia passing through beds of this sparry matter contained in clay.

In the first place we are to observe, that spar is capable of being dissolved either by water or vapour, and suspended imperceptibly in either; and that, though it remains suspended a long time, yet there are occasions of its separating itself from either of these vehicles; such are long standing still and evaporation. What is called the growth and formation of spar, therefore, is properly perhaps only the change of place in this substance, and all that these agents, water and vapours, do, is only to wash it out of the strata of earth or stone, in which it lay in scattered particles, and bring it together into the cracks and crevices of stones, where it may again separate itself, and become more pure and perfect.

The operation of nature, in this case, is very like that of art in the extracting of salts from the various bodies they are mixed with; and spar, in its two states, when blended in the strata of stone, &c. and when pure, and in form of crystals in the cracks, may be compared to alum, for instance, in its bed and when purified. The alum in the common stones, from which it is made, is not perceptible to the eye, but lies in scattered particles; water being added to this takes up the salt, and, when it has been managed by evaporation and rest, yields it again purified and alone, and it forms such crystals on the sides of the vessel, as the other does on the sides of the fissures of stone, which are the vessels where the water, out of which it was formed, was set to evaporate, and to rest a proper time.

That some spars grow from vapours alone, is evident from the stalactitæ, or stony icicles, hanging down from the roofs of our caverns, which, though they grow downwards, yet have many times little plants of the same substance growing out of their sides, and standing upwards contrary to the growth of the other, and evidently formed of the matter separated from the vapours in their ascent, as the stalactitæ themselves are from such as have ascended to the roof, and there been condensed into water, and sent down again in drops. Nor is the sparry matter alone thus raised in vapour, for even the metals, and other bodies, as little likely as those to be thus raised, yet are found to form stalactitæ.

The mundics, in general, though they never form regular stalactitæ, yet often are found adhering to the sides of them, and the metals, particularly iron and lead, form regular stalactitæ; the iron ones very common, and very perfect; the lead less perfect, and more rare; and Dr. Brown gives us abundant instances of spars growing entirely from vapours in the baths of Buda in Hungary. *Phil. Transf. N°. 129.*

SPARADRAP, in pharmacy, &c. a sort of cer cloth, called also tela Gualteri, the form of which is directed as follows: take of the diapalma plaister, and diachylon with the gums, each one pound; cerufs, half a pound; root of orris finely powdered, an ounce and a half. Mix these together, and whilst they are in fusion, dip them in soft worn-out linen rags, so that they may be covered with the plaister on each side; then take them out, spread them, and let them dry; and smooth the surfaces with a knife or spatula. The principal use of these is for issues.

SPARROW, *Passer*, in ornithology, a species of the fringilla.

The common sparrow is the brown fringilla, with a black throat and brown temples. It is larger than the

linnet, and the male is an erect and handsome bird; the head is large, the eyes small, and the beak short; the wings are short, and the tail short and forked.

The reed sparrow, or the fringilla with a black head, brown at the sides, and with a white ring round the neck, and a mottled black and white breast, is a very beautiful and singular bird; of the size of the common linnet; the head is small and depressed, the beak short and black, and the eyes hazel; and in most other particulars it corresponds with the common sparrow.

SPARROW-HAWK, in ornithology, the yellow-legged falco with a white undulated breast, and a fasciated brown tail.

This bird is about the bigness of a pigeon, but considerably longer bodied, in proportion to its thickness; its wings, when expanded, measure twice the length of the body and tail; the tail is short but very strong, thick at the base, very sharp at the point, and considerably hooked; the head is small, somewhat flattened, and of a brownish colour; the eyes are as it were sunk in the head, and their iris is yellow and bright.

SPASM, *Spasma*, or *Spasmus*, in medicine, a convulsion.

A spasm, according to Hoffman, may be universal or particular, salutary or morbid. An universal spasm happens if the whole vascular genus, chiefly the heart and arteries, as also the fibres of the system, are affected, and there is a preternatural constriction therein, whereby the systole and diastole are increased, and the progress of the blood accelerated; this constitutes a fever, whereof a frequent pulse is the most certain sign. The other kind of spasms is particular, and affects only one part of the body, which it constricts, and intercepts the free progress of the blood, rendering it unequal, and sending it in greater plenty to the other parts of the body. But particularly this spastic affection affects the nervous and membranous parts, such as the stomach, and the whole volume of the intestines; whence proceed the hysteric and hypochondriac passions. A spasm is likewise present in hæmorrhages, congestions of the blood, and unequal flux of the fluid in all anxieties and suppressed excretions.

If a violent spasm happens to affect the dura mater, an epilepsy or universal convulsion follows; and convulsive motions of the membranes and nerves have their origin from the medulla spinalis. A spasm is salutary when it destroys the cause of the disease, by taking away the stagnation of the humours, correcting acid caustics, and promoting the excretion of the morbid matter; but it is very pernicious when it constricts the skin and all the excretory vessels, detaining the morbid matter therein, and forcing it upon the vital parts.

In a spasm of the lower jaw, when the patient can neither open his mouth nor eat; as when persons are wounded, and something foreign is lodged therein, or when the nerves are hurt, or when sharp things, such as vitriol, are applied to stop the blood; the cure must be performed according to the diversity of the causes as particularly treated of in surgery; but when this happens spontaneously in infants, it is observed that they generally die, though the best nervous and antispasmodic medicines be used.

In the cynic spasm, or, as it is otherwise called, the Sardonian laughter, if it proceeds from poisons, as it generally does, especially hemlock or oenanthe, Heister directs that they be expelled immediately from the body by a vomit; then giving generous wines, warm with ginger or pepper, as was the practice of the ancients. If it happens from other causes, it must be treated with antispasmodics and nervous medicines, both inwardly and outwardly, and chiefly with plaster of betony and bayberries prepared with oil of amber, and applied to the temples, and behind the ears.

SPASMODIC, something belonging to a spasm or convulsion.

SPATHA, a word used by different authors in various senses; among botanists it expresses that sort of cup which consists of a simple membrane growing from the stalk: this kind of cup is of various figures, often diphyllous, or divided into two parts; often simple; sometimes more divided: it incloses sometimes a single flower, sometimes several flowers together, and these have

have often no perianthium; the spatula is of very different texture and consistence in different plants.

Some authors, by this word, express a rib; others, the surgical instrument called spatula; others, a sort of incision-knife; and by others it is taken for a sword, this last being, indeed, its proper signification, and all the rest being only metaphorical applications of it to different things, which bear some resemblance to a sword.

SPATULA, or SPATHULA, an instrument used by surgeons and apothecaries. This instrument is made of different shapes, according to the various uses of it.

SPAVIN, in the manege, a disease in horses, being a swelling or stiffness usually in the ham occasioning a lameness. There are two kinds of spavins, viz. the ox-spavin, which is a callous tumour at the bottom of the ham on the inside, hard as a bone, and very painful; while it is yet recent, some only halt with it at the first coming out of the stable: the other, which is the dry spavin, is more easily perceived by the horse's raising one of his hind legs with a twitch higher than the other; but sometimes it is found on both legs. This kind, which some also call string-halt, frequently degenerates into the ox-spavin, for which there is no remedy but to apply the fire, and even this is not always successful.

There are two other kinds of spavin which have their seat in the hoof, viz. the blood-spavin, being a soft tumour which grows through the horse's hoof, and is usually full of blood; the other is the bone-spavin, being a crusty substance growing on the inside of the hoof under the joint.

SPAYING, or SPADING, the operation of castrating the females of several kinds of animals, as sows, bitches, &c. to prevent any further conception, and promote their fattening.

SPEAKER of the House of Commons, a member of the house elected by a majority of the votes thereof, to act as a chairman or president, in putting questions, reading briefs or bills, keeping order, reprimanding the refractory, adjourning the house, &c.

The first thing done by the Commons, at the first meeting of a parliament, is to choose a speaker, who is to be approved of by the king, and who, upon admission, begs his majesty, that the commons, during their sitting, may have free access to his majesty, freedom of speech in their own house, and security from arrests.

The speaker is not allowed to persuade or dissuade, in passing of a bill; but only to make a plain and short narrative; nor to vote, unless the house is equally divided. The lord chancellor, or keeper, is usually speaker of the house of lords. The speaker of the convocation is called the prolocutor.

SPEAKING, the art or act of expressing one's thoughts in articulate sounds or words.

SPECIAL, something that is particular, or has a peculiar designation, from the Latin, *species*, in opposition to general, of *genus*.

SPECIES, an idea which relates to some other more general one; or is comprised under a more universal division of a genus.

The word is Latin, derived from the ancient verb *specio*, to see.

Species is a mere term of relation: and the same idea may be a species, when compared to another more general one; and a genus, with regard to a more particular one. Thus body is a genus with regard to an animate and inanimate body; and a species with regard to substance.

What the accurate Artedi has given, as the definition of the species in ichthyology, is not confined to fishes alone, but, with proper regulations, may be made the basis of real distinctions of species in all other natural bodies. Every fish which differs from all the other fishes of the same genus in some external part, whether that difference be in excess or defect, in number or proportion, or even in colour, provided that the difference be fixed and invariable, is properly to be called a distinct species.

The specific differences of fishes are to be drawn from these circumstances; but it is not to be supposed that every species differs in all of them; sometimes only one, sometimes more, occasion the variation.

If any one fish, in regard to all the others of the same genus, is found to be possessed of some external part

which they all want; as, for example, if it have cirri, tubercles in the shape of horns on the head, spines or prickles in the head, or on any other part of the body, the fish is then to be esteemed a distinct species. If one fish differs from the others of the same genus, in the number of any parts, as fins, spines or tubercles, it is then also a distinct species. If one fish differs from another in the proportion of any essential part, as in the having longer jaws, longer teeth, or the like, it is also to be esteemed a truly different species. If one fish differs from another in the figure of some essential part, as of the snout, the back, the teeth, or the tail, or the lineæ laterales, it is to be esteemed a distinct species. If one fish differs from another of the same genus in the excess of parts, having some part that is deficient in the other; or if in number, proportion, or figure of some of the essential parts; the distinction will be the more evident as the greater number of parts differ, and the species will easily be found to be truly distinct.

SPECIES, in logic, is one of the five words called by Porphyry universalis.

SPECIES, in optics, the image painted on the retina, by the rays of light reflected from the several points of the surface of an eye.

SPECIES, in rhetoric, is a particular thing, contained under a more universal one.

SPECIES, in commerce, are the several pieces of gold, silver, copper, &c. which having passed their full preparation and coinage, are current in public.

SPECIES, in algebra, the characters or symbols made use of to represent quantities.

SPECIES, in pharmacy, denotes the ingredients of a compound medicine, as the diascordium in a dry form, or only reduced powder.

The species aromaticæ, according to the Edinburgh Dispensatory, consist of equal parts of canella, lesser cardamom-seeds, mace, and ginger, reduced to powder: but the college of physicians in London, order them to be made of cinnamon, two ounces; and lesser cardamom-seeds husked, ginger, and long pepper, of each one ounce, all beat together into a powder. Both these compositions are agreeable, hot, spicy medicines; and as such may be usefully exhibited in cold phlegmatic habits and decayed constitutions, for warming the stomach, promoting digestion, and strengthening the tone of the viscera in general. The dose is from ten grains to a scruple and upwards.

Change of SPECIES, a term made use of in husbandry to express an expedient the farmer often has recourse to, in order to procure good crops: this is the sowing first one kind of plant, then another, and then a third, and so on, upon the same land: by this means the most is made of the soil; and it is found, when it will no longer give a good crop of the first corn planted on it, it will still give a good one of some other species; and, finally, of pease after all. After this last change of species, it is found necessary, in the common method of husbandry, to renew the land with fallowing and manure, in order to its producing any thing again.

This change of species has been a practice of the farmers of all times, and is recommended, and judged necessary, by most of the writers on this subject: but Tull, in his New System of Horse-hoeing Husbandry, proves that it is not necessary, and that the land only wants proper tillage, when exhausted by one sort of corn, to enable it to produce as good crops of the same corn again. The three fundamental propositions he lays down to prove this, are, first, that plants of the most different nature feed on the same sorts of foods. Secondly, that there is no plant but what must rob every other plant, within its reach, of a part of its nourishment. And, thirdly, that a soil, which is once proper for any kind of vegetable, will continue to be always proper for it, in respect to the sort of food it gives. If only any one of these propositions were true it would follow, that there is no need of a change of species from year to year; and as they are all so, this truth is yet the more incontestable; and experience proves it yet more evidently, for the same land will produce crops of wheat every year, without any change, only by the practice of the horse-hoeing husbandry, instead of the common.

SPECIFIC,

SPECIFIC, in philosophy, that which is peculiar to any thing, and distinguishes it from all others.

SPECIFIC, in medicine, a remedy, whose virtue and effect is peculiarly adapted to some certain disease, is adequate thereto, and exerts its whole force immediately thereon.

The illustrious Hoffman has given a curious account of specific medicines, but it is too long to be inserted here.

SPECIFIC GRAVITY, is that by which one body is heavier than another of the same dimension, and is always as the quantity of matter under that dimension.

Thus a cubical inch of iron is heavier than a cubical inch of wood; for the particles which compose the iron being more solid, and more closely compacted together; or, which is the same, having fewer interstices or vacuities between them, than those of the wood; there is actually more matter contained under the same dimensions in iron than wood; and, therefore, is said to be superficially heavier than wood.

SPECILLUM, or **SPECULUM**, an instrument used by surgeons for searching and dilating wounds.

SPECIOUS ARITHMETIC, that managed and performed by symbols; now generally called algebra. See **ALGEBRA**.

SPECTACLES, in dioptrics, a machine consisting of two lenses, set in silver, horn, &c. to assist the defects of the organ of sight.

Old people, and others who have flat eyes, use convex spectacles, which cause the rays of light to converge so as to fall upon the retina: whereas myopes, or short-sighted persons, use concave lenses for spectacles, which causing the rays to diverge, prevent their meeting before they reach the retina. The convexity or concavity of the glasses, suited to the different degrees of flatness or convexity of people's eyes, is best determined by trial; observing only to use those glasses which are the least convex or concave of any, that will fit the eye: for since they cannot be put quite close to the eye, the less any glass is convex or concave, the less it will magnify or diminish the pictures of objects upon the retina.

Were there no other use of dioptrics, than that of spectacles for defective eyes, the advantage that mankind receives thereby is certainly inferior to none other whatsoever, that is not absolutely requisite to the support of life; for as the sight is the most noble of all our senses, surely that instrument that relieves the eyes when decayed, and supplies their defects, rendering them useful when otherwise almost useless, must needs, of all others, be esteemed of the greatest advantage.

The ancients knew nothing of spectacles, the invention of which is said to have been about the year 1300.

SPECULARIS LAPIS, in natural history, a genus of talcs, composed of large plates visibly separate, and of extreme thinness; and each fissile again separated into a number of plates still finer.

Of this genus there are three species: 1. The white shining specularis, with large and broad leaves, commonly called isinglass and muscovy-glass: its lamellæ or leaves are extremely thin, elastic, and transparent; it makes not the least effervescence with aquafortis, and is not easily calcined in the fire. It is imported in great quantities; the miniature-painters cover their pictures with it; the lantern-makers sometimes use it instead of horn; and minute objects are usually preserved between two plates of it, for examination by the microscope. 2. The bright brown specularis, with broad leaves; a very valuable species, tho' inferior to the former. 3. The purple bright specularis, with broad leaves; which is the most elegant of all the talcs, and not less beautifully transparent than the first kind.

SPECULATIVE, something relating to the theory of some art or science, in contradistinction to practical.

SPECULUM, **MIRROR**, in optics, any polished body impervious to the rays of light; such as water in wells and deep rivers, polished metals, and glasses lined with mercury; or other opaque matter, popularly called looking-glass.

SPEECH, the art or act of expressing a person's thoughts by certain signs invented for that purpose.

SPEECH, in grammar, denotes an assemblage of several words ranged in order.

Grammarians generally make eight parts of speech; i. e. eight kinds of words, generally used in discourse; viz. noun, pronoun, verb, participle, adverb, preposition, interjection, and conjunction; each of which see under its proper article.

Others, particularly English grammarians, refer all words to four general heads or classes, viz. 1. Such words as denote things actually existing, or their properties, which are called nouns or names, as *house, tree, man, horse, convenient, large, &c.* 2. Such words as express action or passion, as *I love, I am loved*; and these are called verbs or affirmations. 3. Such words as denote the manner or way of doing or suffering, as *swiftly, slowly, &c.* which are called adverbs. 4. Particles, or such small words as serve to connect others together, in forming a sentence, as, *and, or, also, before, after, &c.*

SPELL, in general, denotes the same with charm or amulet. See the articles **CHARM** and **AMULET**.

In the sea-language, the word spell signifies to do any work for a short time, and then leave it; therefore, a fresh spell is when fresh men come to work; and to give a spell, is to work in another's room.

SPELLING, in grammar, that part of orthography which teaches the true manner of resolving words into their syllables. See **ORTHOGRAPHY**.

All words are either simple or compound, as *use, diffuse, done, undone*; and the rules for dividing each, must be such as are derived from the analogy of language in general, or from the established custom of speaking; which, for the English language, are reduced to the following rules: 1. A consonant between two vowels must be joined with the latter in spelling, as *na-ture, ve-ri-ly, ge-ne-rous*: except, however, the letter *x*, which is joined to the first, as in *flax-en, ox-en, &c.* and compound words, as in *up-on, un-used, &c.* 2. A double consonant must be divided, as in *let-ter, man-ner, &c.* 3. Those consonants which can begin a word, must not be parted in spelling, as in *de-fraud, re-prove, di-stinct*: however, this rule is found sometimes to fail; for though *gn* begins a word, as *gnaw, gnat, &c.* yet it must be divided in spelling, as in *cog-ni-zance, ma-lig-ni-ty, &c.* 4. Those consonants which cannot begin a word must be divided; as *ld* in *fel-dom, lt* in *mul-ti-tude, mp* in *temper, rd* in *ar-dent*; but, in final syllables, there are exceptions, as *tl* in *ti-tle, dl* in *handle, &c.* 5. When two vowels come together, and are both of them distinctly sounded, they must be separated in spelling, as in *co-e-val, mu-tu-al, &c.* 6. The grammatical terminations, or endings, must be separated in spelling, as *ed* in *wing-ed, edst* in *de-li-ver-edst, ing* in *hear-ing, ance* in *de-li-ver-ance, &c.* 7. Compound words must be resolved into their simple or component words, as *up-on, in-to, never-the-less, not-with-stand-ing, &c.*

SPELTER, in natural history, the same with zinc. See **ZINC**.

SPERMA-CETI, in pharmacy, a white flaky substance, prepared from the oil of a species of whale, called by ichthyologists catodon, by reason it has teeth only in the under jaw.

The ignorance of the people who first used this medicine, gave it a name which seemed to express its being the semen of the whale; but it is, in reality, no more than a preparation of the oil with which that fish abounds.

Sperma-ceti is a fine, bright, white, and semi-pellucid substance, composed of a fine furfuraceous substance, formed into oblong flakes, very light, soft, and unctuous to the touch, inflammable, soluble in oil, but not in watery menstrua; of scarce any smell, when fresh and fine, and of a soft, agreeable, and unctuous taste. The largest, firmest, and whitest flakes of it are to be chosen. It is liable to become rancid and yellowish in keeping, and the smaller fragments contract this bad quality sooner than the larger.

The first knowledge the world seems to have had of sperma-ceti, was the finding it swimming on the surface of the water in the Northern Seas: and we are not to wonder that people who knew no more of its origin than

what they were informed of by those who found it so floating on the sea, referred it to the mineral class, supposing it to be bitumen formed in the bowels of the earth, and thrown up from the bottom of the ocean, as was the opinion of Schroder, and others of his time. It was soon after discovered, however, that the head of a peculiar species of whale afforded a fatty substance, which, when boiled, and properly prepared, was analogous to this. And hence it was soon deduced, that the masses of it first found were of the same origin; that they had been, formerly, an oily matter in this fish, which, getting loose on the perishing of the dead carcase, or by any other means, had been washed and bleached by the salt water, and the sun, into the form in which it was then found. The opinion of its being the sperm or semen of the whale, was about as early as the first discovery that it belonged to that animal, and seems to have been formed merely on account of its whiteness.

The species of whale from the head of which spermaceti was first prepared, and to which it was long thought to be peculiar, is of the number of those ranged in a peculiar genus by Artedi, under the name of catodon, from their having teeth in their under jaw. He has distinguished this species by the name of catodon fistula in cervice, the toothed whale, with a pipe or opening for the discharge of water in its neck. See WHALE.

The spermaceti of the shops was first made from the head of this fish; the oil obtained from its brain, and the diploe of the cranium, furnishing all that we had of it; and hence the considerable price it was long kept at. It was some time after found out, however, that any whale-oil would do as well as this, which occasioned the price to fall considerably. At present it is made in England from whale-oil of any kind, the settlings of our oilmen's larger vessels particularly, which are boiled with a lixivium of German pot-ash, or pearl-ashes, till white and firm; and after several other meltings, and a thorough separation of what saline particles might have got into the matter, it is, when cold, cut out with knives into the flakes we see it in. The process is easy, but it requires care, and a nice inspection towards the end: if not enough boiled, it is apt to turn yellow, and soon grow rancid.

Spermaceti is, therefore, oil of the animal kind, rendered very sweet, and fit for internal use. Its virtues are emollient and pectoral; it is good in coughs, and other disorders of the breast; and excellent in external applications, such as liniments, and the like: it readily dissolves in oil, or other fatty substances, for the latter purposes; and for the former, it blends with the yolk of an egg, and after that mixture with an aqueous fluid, and makes a pleasant emulsion.

SPERMATIC, in anatomy, something belonging to the sperm or seed.

The spermatic vessels, called also *vasa præparantia*, are certain vessels appointed for bringing the blood to the testicles, &c. to be secreted and prepared into seed, and for carrying back again the blood remaining after the secretion is effected. The spermatic vessels are two arteries and as many veins. The spermatic arteries arise, by a very narrow origin, from the fore part of the trunk of the aorta, below the emulgents: their structure is very singular, in that, contrary to the fabric of all other arteries, which are largest at their exit from the trunk, these are smallest at their origin, and grow bigger in their progress towards the testes; by this means the blood receives a check at its first going off for those parts, which disposes it for the future changes, &c. it is to pass through. The same end is answered in quadrupeds, by having these arteries curled and contorted in their passage, like a screw. The reason why nature has taken another method in man, Mr. Cowper observes, is, that in this case the abdominal muscles must have been larger than they are; by which means the intestines would have been frequently let down into the scrotum; an inconvenience which quadrupeds are secured from, by the horizontal position of their bodies. The spermatic arteries, in their progress, meeting with the spermatic veins, enter together with them the inner lamella of the peritonæum; where insinuating into the duplicature of the process, and being clothed therewith, they pass on to within three or

four fingers breadth of the testicles, where they divide into two unequal branches, the biggest of which goes to the testicle, and is distributed therein; and the lesser in the parastrata or epididymis.

The spermatic veins take the same course with the arteries, only a little above the testicles they split into several branches, which uniting, form a plexus called the corpus pampiniforme, or pyramidale. The blood returned by the spermatic veins, is delivered on the right-side to the cava, and on the left into the emulgent vein. Their nerves arise from the plexes of the pelvis and of the loins.

SPERMATOCELE, in medicine and surgery, a kind of rupture occasioned by a distention of the seminal vessels, whereby they are let fall into the scrotum.

SPHACELUS, in surgery and medicine, a total corruption or mortification of any part, occasioned by an interception of the blood and spirits. Sphacelus is distinguished from a gangrene, which is only a mortification begun, and, as it were, the road to a sphacelus.

If a gangrene degenerates into a sphacelus, the part infected must be removed; but the method of doing this is to be varied, according as the part is totally, or only partially affected, and according to the situation of the part, which sometimes does not admit of amputation, as the buttocks, os sacrum, os coccygis, the prominent spines of the vertebræ, and eminences of the scapulæ.

If the part is not corrupted to the very bottom, or cannot be extirpated, our endeavours must tend, first, to stop the progress of the sphacelus; and, secondly, to remove the sphacelated portion.—The progress is stopped by intercepting the communication betwixt the live and sphacelated parts.

In the part thus mortified, all the humours remain at rest in the vessels, or, the vessels being ruptured, the humours are discharged, and become stagnant; but so long as the cohesion between the mortified part remains, the fluids conveyed through these vessels, which are, as yet, alive, will stop in the part where the sphacelus begins, and, consequently, the motion will be suffocated in the live parts contiguous to that which is mortified; and thus the disorder will be propagated.

The infected part is separated, if, after the progress of the disorder is stopped, or whilst it is stopping, the whole part is cauterised, or cut, to the sound subjacent parts, and then corroded by the application of a warm acrid lixivium, till it is consumed to the live parts, till eschars are formed, which are carefully to be softened and removed; but the live parts must, at the same time, be avoided with the greatest caution.

The corrosive lixivium, recommended by Boerhaave, for procuring the separation of a sphacelus, is prepared thus:

Take of quick-lime made of calcined stones, one part. Cover it carefully up with three parts of pot-ash, and, when they are dissolved in a subterraneous place, filtrate and keep the preparation for use. Quick-lime itself, reduced to a powder, may also be sprinkled on the part.

But separations are most advantageously made, if the mortified eschars, by the application of a putrefying remedy, so as to be dissolved into a soft mass, recede from the sound part, whilst the live parts are, in the mean time, cherished with enlivening fomentations.

When the measures above recommended will not produce the desired effect, we must proceed to amputation. See the article AMPUTATION.

SPHENOIDAL SUTURE, in anatomy, a suture thus called from its encompassing the os sphenoides, which it separates from the os frontis, the os petrosum, and the os occipitis.

SPHENOIDES, or Os CRUCIFORME, in anatomy, the seventh bone of the cranium, or skull.

This bone is fixed in manner of a wedge among the other bones of the cranium, and serves as a basis, as it were, to support several of them, and some of those of the upper jaw: the figure of this bone is very irregular; in its upper part is seen the sella equina, or turcica, under which there is a sinus: this is sometimes double, and opens into the nostrils: sometimes it is totally wanting: it is called the sphenoidal sinus. The sphenoides has thirteen apophyses; six of them are internal, and are placed near the sella equina; and the other seven are external;

ternal; four of these are of a pterygoide form, and thence named pterygoide apophyses; two of the other three are very small and styloide, and the seventh is placed under the vomer: there are also three fossæ, or cavities, in this bone, one in the fella equina, and the other between the pterygoide apophyses.

SPHENOPHARYNGÆUS, in anatomy, a pair of muscles, called also the pterygopharyngæus.

SPHENOSTAPHYLINUS, in anatomy, a muscle of the larynx. It descends from a round fleshy origination, near the root of a process of the os sphenoides, and from thence runs obliquely to the uvula, and is inserted into the hinder and upper part, where it joins its partner. It serves to draw the uvula upwards and backwards, and hinders the masticated aliment from passing into the foramina narium, in deglutition.

SPHERE, *σφαῖρα*, in geometry, a solid body contained under one single surface, and having a point in them idle called the center, whence all lines drawn to the surface are equal.

If the semi-circle ADB (plate CXXII. fig. 3.) be turned about upon its diameter AD as an axis, the semi-periphery ABD will describe the surface of a sphere; and each point, as M, will describe the circumference of a circle, whose radius will be MP, the right-line of the arch AM. Put $AP = x$, $PM = y$, $AC = r$, and the whole circumference $= c$; then, as $r : c :: y : \frac{cy}{r}$, the

circumference described by the point M. Let Mm be an infinitely small arch, and draw mp parallel to MP ; then will $MR = x$: and because the triangles CMP and MmR are similar, it will be as $PM : CM :: MR$ to Mm . That is, $y : r :: x : \frac{rx}{y}$, which being multiplied by $\frac{cy}{r}$, the circumference, formed by the point M,

will give $\frac{cyrx}{ry} = cx$, the area of the increment formed by Mm ; this multiplied by Qr , or, which is the same thing, putting Qr in the room of x , we shall have Qcr for the intire surface of the sphere; for, when Mm becomes equal to ABD , x becomes equal to Qr .

Hence it is manifest, that the surface of the sphere is equal to four times the area of the greatest circle: for $Qcr =$ the surface of the sphere, is equal to four times $\frac{cr}{2}$, the area of the greatest circle; but as the diameter of any circle is to its circumference, so is the square of the same diameter to the surface of the generated sphere: therefore it will be as 1, to 3,14159, &c. so is the square of the diameter of a sphere to its superficies; and, if we multiply its superficies by $\frac{1}{2}$ of the diameter, the product will be the solidity.

Hence the square of the diameter being multiplied by 3,14159, &c. or the square of the radius by 12,56637, &c. the product will be the superficial content.

SPHERE, in astronomy, that concave orb, or expanse, which invests our globe, and in which the heavenly bodies appear to be fixed, and at an equal distance from the eye.

The better to determine the places of the heavenly bodies in the sphere, several circles are supposed to be described on the surface thereof, hence called the circles of the sphere: of these, some are called great circles, as the equinoctial, ecliptic, meridian, &c. and others, small circles, as the tropics, parallels, &c. See each under its proper article.

Armillary SPHERE. See the article **ARMILLARY Sphere**.

SPHERE of Activity of a Body, is that determinate space or extent, to which, and no farther, the effluvia continually emitted from that body, reach; and where they operate, according to their nature. See **POWER**.

SPHERICAL ANGLE, TRIANGLE, and TRIGONOMETRY. See the article **ANGLE, TRIANGLE, and TRIGONOMETRY**.

SPHERICS, is that part of geometry which treats of the position and mensuration of arches of circles, described on the surface of a sphere.

SPHEROID, in geometry, a solid generated by the entire revolution of a semi-ellipsis about its axis.

The word is formed from the Greek *σφαῖρα*, a sphere, and *ειδῶς*, resemblance.

When the figure is generated by the revolution of the semi-ellipsis about its transverse or greater axis, it is called a prolate or oblong spheroid; and when generated by the revolution of a semi-ellipsis about its conjugate or lesser diameter, it is called an oblate spheroid. Every spheroid is equal to two thirds of its circumscribing cylinder.

As to the superficies of a spheroid, Mr. Huygens gives the two following constructions in his *Horolog. Oscill.* For describing a circle equal to the superficies of an oblong and prolate spheroid. 1. Let an oblong spheroid be generated by the rotation of the ellipsis ADBE, (plate CXXII. fig. 4.) about its transverse axis AB, and let DE be its conjugate; make DF equal to CB, or let F be one of the foci, and draw BG parallel to FD, and about the point G, with the radius BG, describe an arch, BHA, of a circle; then between the semi-conjugate CD, and a right line equal to DE + the arch AHB, find a mean proportional, and that will be the radius of a circle equal to the superficies of the oblong spheroid. 2. Let a prolate spheroid be generated by the rotation of the ellipsis ADBE (fig. 5.) about its conjugate axis AB. Let F be one of the foci, and bisect CF in G, and let AGB be the curve of the common parabola whose base is the conjugate diameter AB, and axis CG. Then if between the transverse axis DE, and a right line equal to the curve AGB of the parabola, a mean proportional be taken, the same will be the radius of a circle equal to the surface of that prolate spheroid.

SPHINCTER, in anatomy, a term applied to a kind of circular muscles, or muscles in form of rings, which serve to close and draw up several orifices of the body, and prevent the excretion of the contents of the sphincter vesicæ. See the article **BLADDER**.

SPHINX, *σφίγξ*, in sculpture, &c. a figure or representation of a monster of that name, famed among the ancients, now mostly used as an ornament in gardens, terraces, &c. It is represented with the head and breasts of a woman, the wings of a bird, the claws of a lion, and the rest of the body like a dog. It is supposed to have been engendered by Typhon, and sent by Juno to be revenged on the Thebans. Its office, they say, was to propose dark enigmatical questions to all passers by; and if they did not give the explication thereof, to devour them. It made horrid ravages, as the story goes, on a mountain near Thebes, and could not by any means be destroyed, till after Œdipus had solved the following riddle. "What animal is it that in the morning walks on four legs, at noon on two, and at night on three?" The answer was, "Man."

Among the Egyptians, the sphinx was the symbol of religion, by reason of the obscurity of its mysteries: and on the same account the Romans placed a sphinx in the porch of their temples.

SPICA VIRGINIS, a star of the first magnitude, in the constellation Virgo. Its place is in the more southerly hand. Its longitude, according to Mr. Flamsteed, is $19^{\circ} 31' 22''$: its latitude, $2^{\circ} 1' 59''$ south.

SPICE, any kind of aromatic drug that has hot and pungent qualities: such are pepper, nutmeg, ginger, cinnamon, cloves, &c.

Some also apply the word to divers other medicinal drugs brought from the East: as senna, cassia, frankincense, &c.

SPIDER, in zoology, the name of a well known insect, of which we have a great number of species.

The spider affords to the sagacious observer, as well without as with the assistance of glasses, a great many extremely curious particulars. As the fly, which is the spider's natural prey, is an animal extremely cautious and nimble, and usually comes from above, it was necessary the spider should be furnished with a quick sight, and an ability of looking upwards, forwards, and sideways, at the same time; and the microscope shews, that the number, structure, and disposition of its eyes, are wonderfully adapted to the serving all these purposes.

Most

Most spiders have eight eyes: two on the top of the head or body, for there is no division between them, the spider having no neck; these look directly upwards: there are two more in front, placed a little below these, and discovering all that passes forwards, and on each side: a couple more, one whereof points sideways forwards, and the other sideways backward; so that it can see almost quite round it. All kinds of spiders have not, however, this exact provision; for in some we find ten, and in others only six, or four. The eyes of the spider are not pearled; and the field-spiders, or long-legs, have no more than two eyes.

Whatever be the number of the spider's eyes, they are however all immoveable and transparent, and are situated in a most curious manner. The best way of viewing them with the microscope, is to cut off the legs and tail, and leave only the head for examination.

All spiders have eight legs, which they employ in walking; and two shorter, called arms, which they use in seizing their prey. All the legs are thickly beset with hairs; each has six joints, and ends with two hooked claws, which are serrated on their inside; by means of these teeth, or jags in their claws, they seize very fast hold of any thing, and behind these there is a sort of spur, which is perfectly smooth. Besides these, nature has allotted this creature, for the seizing its prey, a pair of sharp crooked claws, or forceps, in the forepart of its head. These stand horizontally, and, when not exerted for use, are concealed in two cases contrived for their reception, in which they fold like a clasp-knife, and there lie between two rows of teeth, which are likewise employed to hold fast the prey.

Each of these claws, or pincers, has a small slit near its point, according to Lewenhoeck, like that in a viper's tooth, through which he supposes that a poisonous juice is, in like manner, thrown out. But Dr. Mead, in his Essay on Poisons, differs wholly from this opinion, having never been able, on repeated examinations, to discover any such opening, not even in the claws of the great American spider; which, being above fifty times bigger than any of the European spiders, would more easily have discovered this opening, if nature had allotted any to this part of the animal. Besides, repeated observations also convinced him that nothing dropped out of the claws, which were always dry, while the spider bit any thing, but that a short white proboscis was, at the same instant, thrust out of the mouth, which instilled a liquor into the wound. And the same author observes, that the quantity of liquor, emitted by our common spiders when they kill their prey, is visibly so great, and the wounding weapons so minute, that they contain but a very inconsiderable portion thereof, if it were to be discharged that way. *Baker's Microscope.*

Spiders frequently cast their skins, which may be found in their webs perfectly dry and transparent; and from such skins the forceps, or claws, for they are always shed with the skins, may easier be separated, and examined with much greater exactness, than in the common spider while living.

The spider's manner of weaving its web is very wonderful. The creature has five little teats, or nipples, near the extremity of the tail; from these there proceeds a gummy liquor, which adheres to every thing it is pressed against, and, being drawn out, hardens instantly in the air, and becomes a string, or thread, strong enough to bear five or six times the weight of the spider's body. This thread is composed of several finer ones, which are drawn out separately, but unite together at two or three hairs breadth distance from the creature's body. These threads are finer or coarser, according to the bigness of the spider that spins them. Mr. Lewenhoeck has computed, that a hundred of the single threads of a full grown spider are not equal to the diameter of the hair of his beard; and consequently, if the threads and hair be both round, ten thousand such threads are not bigger than such a hair. He calculates farther, that, when young spiders first begin to spin, four hundred of them are not larger than one which is of full growth: allowing which, four millions of a young spider's threads are not so big as the single hair of a man's beard.

The eggs of some spiders are a very pleasing microscopic object; they are round at one end, and flattish at the other, with a depression in the center of the flattish end, and a yellowish circle round it. The colour of these eggs is a pearly or bluish white, and when the young spiders hatch, they come out in their perfect form, and run about very nimbly.

The female spider deposits her eggs, to the number of five or six hundred, in a bag composed of her own web, which she either carries under her belly, or hides in some very safe recess. *Phil. Transf. N^o. 272.*

SPIEL, in the glass-trade, an iron instrument, hooked at the end and pointed, with which the workmen take the metal up out of the melting-pots, for proofs or essays, to see whether it be fit for work.

SPIKE, or *Oil of SPIKE*, a name given to an essential oil distilled from lavender, and much used by the varnish-makers, and the painters in enamel, and of some use in medicine. It is brought from Provence, and other parts of France, where the lavender is called aspic, and thence came the name of oil of spike. This oil, when in perfection, is very limpid; of a pleasant yellowish colour; very fragrant; possessing, in an eminent degree, the peculiar smell generally admired in the flowers. In medicine it is used, both externally and internally, in paralytic and lethargic complaints, rheumatic pains, and debilities of the nervous system. The dose is from one drop to five or six; but our artificers, in their varnishes, use more of this oil than the apothecaries do: and wanting it at a cheap rate, they have taught the druggists, who used to import and sell it to them, so many ways of adulterating it, that at present it is scarce any where to be met with genuine: and so coarse an ingredient as common oil of turpentine is used as the basis of all the counterfeits: they also sometimes adulterate it with spirit of wine. But both these cheats are easily discovered: that mixed with spirit of wine may be known by only mixing the whole with water, in which case the water, uniting with the spirit, leaves the oil at the top alone; that mixed with oil of turpentine, is discovered by burning a spoonful of it; for the genuine oil of spike burns with a clear flame and without smoke, and its smell, while burning, is very fragrant; whereas, when there is oil of turpentine mixed, it burns more furiously, emits a thick smoke, and is of a very bad smell. This oil is distilled from the smaller species of lavender, in the common way, by the alembic. See LAVANDULA.

SPINA BIFIDA, in anatomy, a parting of the spinal processes into two rows: the existence of such a case is doubted. See SPINE.

SPINA VENTOSA, in surgery and medicine, that species of corruption of the bones which takes its rise in the internal parts, and by degrees enlarges the bone, and raises it into a tumour, and which, when it happens to children, is termed by Severinus, and many others, *pædarthrocaces*.

SPINACHIA, or SPINACIA, SPINACH, or SPINAGE, in botany, a genus of plants: it hath an apetalous flower consisting of many stamina included in the flower-cup, which are produced in spikes upon the male plants, which are barren; but the embryos are produced from the wings of the leaves on the female plants, which afterwards becomes a roundish or angular seed, which in some sorts has thorns adhering to it.

Winter spinage should be sown upon an open spot of ground towards the latter end of July, observing, if possible, to do it when there is an appearance of rain: for, if the season should prove dry for a long time after the seed is sown, the plants will not come up regularly; and many times there will not be half a crop. When the spinage is come up, the ground should be hoed to destroy the weeds, and also to cut up the plants where they are too close, leaving the remaining plants about three or four inches asunder: but this should always be done in dry weather, that the weeds may be destroyed soon after they are cut.

About a month or five weeks after the first hoeing, the weeds will begin to grow again; therefore the ground should be then hoed again the second time, observing, as before, to do it in dry weather. But if the season should prove moist, it will be proper to gather the weeds up after they

they are cut, and carry them off the ground; for, if the spinage is not cleaned from weeds before winter, they will grow up, and stifle it so, that in wet weather the spinage will rot away.

In October, the spinage will be fit for use; when you should only crop off the largest leaves, leaving those in the center of the plants to grow bigger; and thus you may continue cropping it all the winter and spring, until the young spinage, sowed in the spring, is large enough for use, which is commonly in April; at which time the spring advancing, the winter spinage will run up to seed; so that you will cut it up, leaving only a small parcel to produce seeds.

The two sorts with smooth seeds produce much larger and thicker round leaves than the former; but, being somewhat tenderer, are always sown in the spring.

These are either sown upon an open spot of ground, by themselves, or else mixed with radish-seed, as is the common practice of the London gardeners, who always endeavour to have as many crops from their land in a season as possible; but, where land is cheap in the country, it will be the better method to sow it alone without any other sort of seed mixed with it; and, when the plants are come up, the ground should be hoed to destroy the weeds, and cut out the plants where they are too close, leaving the remaining about three inches asunder; and, when they are grown so large as to meet, you may then cut off a part of it for use, thinning the plants that they may have room to spread; and this thinning may be twice performed, as there is occasion for the spinage; at the last of which, the roots should be left eight or ten inches asunder. If then you hoe the ground over again, to destroy the weeds, it will be of great service to the spinage; for, if the land is good upon which it was sown, the third sort, with this management, will many times produce leaves as large as the broad-leaved dock, and be extremely fine.

But, in order to have a succession of spinage through the season, it will be proper to sow the seed at three different times in the spring; the first, early in January, which must be on a dry soil; the second, the beginning of February, upon a moister soil: and the third, the beginning of March, which should be on a very moist soil: and this third sowing should be hoed out thinner at the first time of hoeing it, than either of the sowings; for there will be no necessity to leave it for cutting out thin for use, because the former sowings will be sufficient to supply the table till this third sowing is full grown; besides, by leaving it thin at first, it will not be apt to run up to seed so soon as it would if the plants were close. *Miller's Gard. Diet.*

SPINALIS, in anatomy, the names of several muscles, &c. of the spine, but more particularly that of a muscle on the side of the neck, arising from the five superior processes of the vertebrae of the thorax, and the inferior of the neck; and which in its ascent, becoming more fleshy, is inserted into the inferior part of the vertebrae of the neck laterally. It serves to draw the neck backwards.

Other muscles of the back, neck, &c. called by some anatomists spinalis, are, 1. The Spinalis cervicis, called by others transversalis: 2. Spinales colli minores, are muscles lying between the six spinal apophyses of the neck, and between the last of the neck and the first of the back, called by some interspinales. Other muscles of this name are, 3. The spinalis dorsi, being called by some, a part of the semi-spinatus; and by others, a part of the longissimus dorsi. 4. The spinalis dorsi major, is a pretty long and slender muscle, lying upon the lateral parts of the extremities of the spinal apophyses of the back, called, by some, semi-spinalis. 5. Spinales dorsi minores are muscles of two kinds, some going laterally from the extremity of one spinal apophyses to another, being often mixed with the short fasciculi of the spinalis major; the rest lie directly between the extremities of two neighbouring spinal apophyses; being separated from those on the other side by the spinal ligament; these are sometimes termed interspinales. 6. Spinales, and transversales lumborum, are some fasciculi which run up from the superior false spines of the os sacrum, to the lower spinal apophyses of the loins.

The spinal accessory nerve of Willis, is a sort of ninth

pair of nerves of the neck, arising from the spinal marrow, about the origin of the third or fourth pair, and passing through the great foramen of the os occipitis up into the cranium: it is then joined to the par vagum, and coming out of the cranium again by the same aperture, it recedes from the par vagum, and is bent back to the musculus scapulae cucullaris or trapezius.

SPINE, SPINA-DORSI, in anatomy, the bony column reaching from the head down to the anus; being the series or assemblage of vertebrae which sustain the rest of the body, contain the spinal marrow, and to which the ribs are connected.

The usual division of the spine is into the neck, the back, the loins, and the os sacrum and coccygis.

Luxations, fractures, and other injuries of the SPINE. The signs common to luxations in the spine are chiefly the following: The back itself is found to be crooked, after some external violence has been inflicted upon it; the patient can neither stand nor walk, and his whole body seems to be paralytic; the parts which are beneath the luxated vertebrae are nearly without all sense and motion; the excrements and urine cannot be discharged, or else they are sometimes emitted involuntarily; the lower extremities grow dead by degrees, and at length death itself follows: but these symptoms vary in proportion to the degree of violence in the luxation. Where there is but one vertebra luxated, the curvature is gibbous, making a sort of angle: if the processes of the vertebrae are displaced forwards, then the spine will seem to bend inwards, and the pains will be more gentle when the patient lies on his back: if the vertebra is luxated on the right side, the body will incline towards the left, and vice versa. Luxations of the spinal vertebrae are in general very difficult to reduce; but the following seems to be the best method of reducing them, according to Heister: When the apophyses are dislocated on both sides, the patient is to be laid leaning upon his belly over a cask, drum, or some other gibbous body, and then two assistants are strongly to press down both ends of the spine on each side; then the surgeon is to press down the luxated vertebrae, and at the same time to push nimbly the superior part of the body upwards, by which means the luxated vertebra are sometimes commodiously reduced into their right places: but if success should not attend the first time, the method should be repeated two or three times more. When the vertebra comes out on one side, the patient is then to be placed as before, but so that when the left apophysis is displaced, one assistant may press the lower vertebrae inwards to the right, and another assistant may depress the right humerus, and vice versa. For the remainder, it seems proper, after the vertebrae are reduced, to bathe the spine with spirit of wine, or to lay on compresses dipped in spirit of wine camphorated, and to bind the parts up with the napkin and scapulary.

When any of the vertebrae are fractured either by a fall, blow, or any other cause, without hurting the spinal marrow, it is to be supposed that the fracture is confined to some of the oblique or spinal processes, and therefore the patient will be in no great danger; but when the body of the vertebrae is either broke or split, and the contiguous spinal marrow bruised or compressed, all the parts of the limbs and viscera beneath that vertebra will become immovable and rigid, and death will sooner or later follow the accident: and if the transverse processes of the vertebrae are broke, which incline towards the cavity of the thorax, it is scarce possible that the heads of the ribs, which are there connected, should escape being fractured. These fractures are to be judged of from the nature of the external violence which occasioned them, from the pains seated about the affected vertebra, and from the touch, eye, &c. When only the processes of the vertebrae are found broken, it will be much the best way to force them into their places with the fingers, placing narrow compresses dipt in warm spirit of wine on each side of the vertebrae, and over them slips of thick pasteboard, to be kept on by the napkin and scapulary.

When the spine is so injured that the spinal marrow is wounded, such wounds as are slight may be dressed with Peruvian balsam, essence of myrrh, or medicines of a like nature, mixed with a quantity of honey of roses

spread upon a pledget, and applied moderately warm; by which means, if the patient is of a good constitution, the parts sometimes heal, but large wounds here bring certain death.

SPINET, or SPINET, a musical instrument ranked in the second or third place among the harmonious instruments of the same nature with the harpsichord.

This instrument has its name from the small quills that strike the string being supposed to resemble *spinæ*, or thorns. See HARPSICHORD.

SPINNING, in commerce, the act or art of reducing silk, flax, hemp, wool, hair, or other matters, into thread. Spinning is either performed on the wheel with a distaff and spindle, or with other machines proper for the several kinds of working. Hemp, flax, nettle-thread, and the like vegetable matters, are to be wetted in spinning; silks, wools, &c. are to be spun dry, and do not need water; but there is a way of spinning silk as it comes off the cases or balls, where hot and even boiling water is to be used.

SPINOSISM, the doctrine of Spinoza; or atheism and pantheism, proposed after the manner of Spinoza.

Benedict Spinoza, or Espinoza, was a man well known in Holland. He was born a Jew at Amsterdam, but did not make profession of any religion, either the Jewish or Christian.—He composed several books in Latin; the most celebrated whereof is his *Tractatus Theologico-Politicus*, wherein he endeavours to overturn the foundation of all religion: the book, accordingly, was condemned by a public decree of the states; though it has since been sold publicly, and even reprinted, both in Latin and French, in that country, and lately in English at London.

Spinoza, here, insinuates, that all religions are only political engines, calculated for the public good; to render the people obedient to magistrates, and to make them practise virtue and morality.

He does not here lay down his notion of the Deity openly, but contents himself with suggesting it.—In his *Ethics*, published among his posthumous works, he is more open and express; maintaining, that God is not, as we imagine him, an infinite, intelligent, happy, and perfect being; nor any thing, but that natural virtue, or faculty, which is diffused throughout all creatures.

Spinoza, in his *Tractatus* above-mentioned, is very full on the subject of the authors of the scriptures; and endeavours to shew, that the Pentateuch is not the work of Moses, contrary to the common opinion, both of the Jews and Christians. He has also his particular sentiments, as to the authors of the other books.—This part of the work has been answered by M. Huet, in his *Demonstratio Evangelica*; and by M. Simon, in his *Hist. Crit. du Vieux Test*.

Spinosism is a species of naturalism, or pantheism, or hylotheism, as it is sometimes called, that is, of the dogma which allows of no other God but nature, or the universe; and, therefore, makes matter to be God. Accordingly, Buddeus, in a dissertation *De Spinozismo ante Spinozam*, proves at large, that Spinoza's doctrine of God and the world is far from being his own invention, but that it had been held by many philosophers of different sects, both among the Chaldeans and Greeks. It is certain, the opinion of the Stoics, and those who held an *anima mundi*, was not far from it. Lucan introduces Cato discoursing thus:

*Estne Dei sedes nisi terra, & aër,
Et cælum, & virtus? superos quid quærimus ultra!
Jupiter est quocumq; vides, quocumq; moveris.*

LUC. PHARS. lib. ix. v. 578.

Strato likewise, and others among the Peripatetics, maintained something very like it; and what is more, though no ancient sect seems farther removed from Spinosism than the Platonic, as they attributed the greatest freedom to God, and carefully distinguished him from matter; yet Gundlingius has proved at large, that Plato gave matter much the same origin with Spinoza. But the sect that approached nearest to Spinosism, was that which taught that all things were one, as Xenophanes the Colophonian, Parmenides Melissus, and especially Zeno Eleates, whence it obtained the name of the Eleatic

system of atheism. To the same may also be reduced the opinion of those, who held the first matter for God, as Almaricus and David of Dinantum. Add, that the sect of Foe in China and Japan, that of the Soufi in Persia, and that of the Zindikites in Turkey, are found to philosophise much after the manner of Spinoza.

The chief articles in Spinoza's system are reducible to these: That there is but one substance in nature; and that this only substance is endued with an infinite number of attributes, among which are extension and cogitation. That all the bodies in the universe are modifications of this substance considered as it is extended; and that all the souls of men are modifications of the same substance, considered as cogitative. That God is a necessary and infinitely perfect being, and is the cause of all things that exist, but is not a different being from them. That there is but one being and one nature; and that this nature produces, within itself, by an immanent act, all those which we call creatures. And that this being is at the same time both agent and patient, efficient cause and subject; but that he produces nothing but modifications of himself.

Thus is the Deity made the sole agent as well as patient in all evil, both physical and moral; that called *malum poenæ*, as well as *malum culpæ*: a doctrine fraught with more impieties than all the heathen poets have published concerning their Jupiter, Venus, Bacchus, &c. What seems to have led Spinoza to frame this system, was the difficulty of conceiving either that matter is eternal, and different from God, or that it could be produced from nothing, or that an infinite and free Being could have made a world such as this is. A matter that exists necessarily, and which nevertheless is void of activity, and subject to the power of another principle, is an object that startles our understanding; as there seems no agreement between the three conditions.—A matter created out of nothing is no less inconceivable, whatever efforts we make to form an idea of an act of the will that can change what before was nothing into real substance. Besides, its being contrary to that known maxim of philosophers, *Ex nihilo nihil fit*. In fine, that an infinitely good, holy, free Being, who could have made his creatures good and happy, should rather choose to have them wicked, and eternally miserable, is no less incomprehensible; and the rather, as it seems difficult to reconcile the freedom of man with the quality of a being made out of nothing.

These appear to have been the difficulties which led Spinoza to search for a new system, wherein God should not be distinct from matter, and wherein he should act necessarily, and to the extent of all his power, not out of himself, *ad extra*, but within himself. But it is certain, if the new system rescue us from some difficulties, it involves us in others much greater. For,

1. It is impossible the universe should be but one substance, since every thing that is extended must necessarily have parts; and what has parts must be compounded. And, as the parts of extension do not subsist in each other, it follows, either that extension in the general is not substance, or that every part of extension is a different substance. Now, according to Spinoza, extension in general is an attribute of substance. And he allows, with other philosophers, that the attributes of substance do not differ really from the substance itself. He must therefore allow, that extension in general is substance: whence it will follow, that every part of extension is a particular substance which overturns the whole system.

If it be objected, that Spinoza does not consider different bodies as different parts of extension, but as different modifications of it; the distinction between part and modification, we doubt, will hardly save him. For let him avoid the word part as much as he pleases, and substitute that of modality, or modification for it, the doctrine will amount to much the same: the characters of diversity are not less real and evident, when matter is divided into modifications, than when it is divided into parts. The idea of the universe will still be that of a compound being, or an aggregate of several substances.

For proof of this, it may be observed, that modalities are beings which cannot exist without the substance which modifies them; whence it follows, that the substance

stance must be found where-ever its modalities are found; and even that the substance must be multiplied in proportion as the number of incompatible modifications is multiplied: so that, where-ever there are five or six of these modifications, there must be five or six substances. It is evident, that a square figure and a circular figure are incompatible in the same piece of wax. Whence it follows, that the substance modified by the square figure cannot be the same substance with that modified by the round figure. So, when I see a round and a square table in a room, I may safely assert, that the extension which makes the subject of the round table is a distinct substance from the extension which is the subject of the square table: since otherwise it would follow, that the square and round figures might be found in the same subject at the same time.—The subject, therefore, that is modified by two figures, must be two substances.

2. If it be absurd to make God extended, as this robs him of his simplicity, and makes him be composed of parts; it is still worse to reduce him to the condition of matter, the lowest of all beings, and that which most of the ancient philosophers ranked immediately above nothing: matter! the theatre of all sorts of changes, the field of battle of contrary causes, the subject of all corruptions and generations; in a word, the being most incompatible with the immutability of the Deity!

The Spinozists, indeed, maintain, that it is not susceptible of any division; but the argument they alledge, in proof of it, we have elsewhere shewn to be false: it is, that for matter to be divided, it is necessary that one of the parts be separated from the other by a void space, which is impossible: since there is no vacuum in nature.

3. If Spinozism appear extravagant, when we consider God as the subject of all the mutations, corruptions, and generations in bodies; it will be found still worse, when we consider him as the subject of all the modifications of thinking. It is no small difficulty to unite extension and thinking in the same substance; since it is not an union like that of two metals, or of water and wine, that will serve the purpose: these last require only juxtaposition; whereas to combine thinking and extension requires an identity; thinking and extended are two attributes identified with the substance; and consequently are identified with each other, by the fundamental rule of all logic.

Again, when we say, that a man denies this, affirms that, likes that, &c. we make all those attributes fall on the substance of his mind, not on his thoughts, which are only accidents or modifications of it. If therefore what Spinoza advances be true, that men are modalities of God; it would be false to say, 'Peter denies, likes, wills,' &c. since, in reality, on this system, it is God that denies, wills, &c. and consequently all the denominations which arise from the thoughts, desires, &c. of men, fall properly and physically on the substance of God. From whence it also follows, that God affirms and denies, loves and hates, wills and not wills the same thing, at the same time, and under the same conditions, contrary to the great principle of reasoning: '*Opposita sunt quæ & neq; de se invicem, neq; de eodem tertio secundum idem, ad idem, eodem modo atq; tempore verè affirmari possunt*;' which must be false, if Spinozism be true: since it cannot be denied but some men love and affirm what others hate and deny, under all the conditions expressed in the rules.

4. But, if it be physically absurd to say the same subject is modified at the same time with all the different thoughts of all men, it is horrible when we consider it in a moral light. Since it will follow, that the infinite, the all-perfect Being is not constant, is not the same one moment, but is eternally possessed even with contrary passions; all the uniformity in him, in this respect, will be, that for one good and wise thought he will have twenty foolish and wicked ones. He will not only be the efficient cause of all the errors, iniquities, and impurities of men, but also the passive subject of them, the *subjectum inhaesionis*. He must be united with them in the closest manner that can be conceived, even by a penetrative union, or rather an identity, since the mode is not really distinct from the substance modified.

Several have undertaken to refute Spinoza's doctrine,

particularly the learned Dr. Clarke; we have also an examination of Spinozism, and Mr. Bayle's objections against this system, by Mons. de Jariges, in the *Mem. de l'Acad. de Berlin*. Wolfius has also given a refutation of Spinoza, in his *Theol. Nat. Part 2*.

SPIRAL, in geometry, a curve line of the circular kind, which, in its progress, recedes from its center.

A spiral, according to Archimedes, its inventor, is thus generated; if a right line, as A B (plate CXXII. fig. 6.) having one end fixed at B, be equally moved round, so as with the other end A to describe the periphery of a circle; and, at the same time, a point be conceived to move forward equally from B towards A, in the right line B A, so as that the point describes that line, while the line generates the circle; then will the point, with its two motions, describe the curve-line B 1, 2, 3, 4, 5, &c. which is called the helix or spiral line, and the plane space, contained between the spiral line and the right line B A, is called the spiral space.

If also you conceive the point B to move twice as slow as the line A B, so as that it shall get but half way along the line B A, when that line shall have formed the circle; and if then you imagine a new revolution to be made of the line carrying the point, so that they shall end their motion at last together, there will be formed a double spiral line, and the two spiral spaces, as you see in the figure.

From the genesis of this curve, the following corollaries may be easily drawn. 1. The lines B 12, B 11, B 10, &c. making equal angles with the first and second spiral, as also B 12, B 10, B 8, &c. are in arithmetical proportion. 2. The lines B 7, B 10, &c. drawn any how to the first spiral, are to one another as the arches of the circle intercepted betwixt B A and those lines. 3. Any lines drawn from B to the second spiral, as B 18, B 22, &c. are to each other as the aforesaid arches, together with the whole periphery added on both sides. 4. The first spiral space is to the first circle as 1 to 3. And, 5. The first spiral line is equal to half the periphery of the first circle; for the radii of the sectors, and consequently the arches, are in a simple arithmetic progression, while the periphery of the circle contains as many arches equal to the greatest; wherefore the periphery to all those arches is to the spiral lines as 2 to 1.

SPIRAL, in architecture and sculpture, implies a curve that ascends, winding about a cone or spire, so as all the points thereof continually approach the axis.

It is distinguished from the helix by its winding around a cone; whereas the helix winds in the same manner around a cylinder.

Proportional SPIRALS, are such spiral lines as the rhumb lines on the terrestrial globe, which, because they make equal angles with every meridian, must also make equal angles with the meridians in the stereographic projection on the plane of the equator; and therefore will be, as Dr. Halley observes, proportional spirals about the polar point.

SPIRE, *Spira*, in architecture, was used by the ancients for the base of a column, and sometimes for the astragal or tore. But, among the moderns, it denotes a steeple that continually diminishes as it ascends, whether conically or pyramidally.

SPIRIT, *Spiritus*, in metaphysics, an incorporeal being or intelligence; in which sense, God is said to be a spirit, as are angels and the human soul.

The word spirit is, indeed, used in general to denote all thinking intelligent substances; but it would be the height of folly to imagine, because this name is applied to the Creator as well as to the human soul, that therefore they partake of one common nature, and differ only as different modifications of the same substance: wherefore, when we call God a spirit, we ought by no means rashly to presume, that he is so in the same sense in which the human soul is a spirit.

However, though we readily own there may be various ranks of spiritual beings; yet as we have no conceptions of the powers and operations of intellectual natures distinct from those of our own minds, we are necessitated to conceive of them in a manner suited to our knowledge; and when we would rank them into species, according to the degrees of superiority they are imagined in the scale of being, we ascribe to them what we find most excellent.

lent in ourselves, as knowledge, thinking, foresight, &c. and those in different measures, proportioned to the station peculiar to each rank. But that this is a very imperfect way of distinguishing the various orders of intellectual beings, needs not many words to make appear; especially if we consider, that the manner of communicating their thoughts without the intervention of bodily organs, is a thing to us altogether incomprehensible; which necessarily leads us to suppose, that they have ways of perception and knowledge, whereof our faculties cannot give us any notice.

SPIRITS, or ANIMAL SPIRITS, in physiology. See ANIMAL SPIRITS.

Our perceptions and actions are supposed to depend on the facility with which these spirits pass from the brain to the nerves, and back from the nerves to the brain: for if the brain, the cerebellum, or the spinal marrow is hurt, there happens in all the parts where the nerves are distributed, which proceed from the disordered part, convulsions and palsies; and if any nerve is tied or cut, the parts below the ligature lose their sense and motion, while those above continue in their former state.

SPRIT, in chemistry, a name applied to several very different substances; however, in general, it denotes any distilled volatile liquor that is not insipid, as phlegm, or pure water, nor inflammable as oil: but under this general idea are comprehended liquors of quite opposite natures, some being acid, and others alkaline; which last are such enemies to the former, that as soon as they are put together they raise a violent effervescence, and grow hot; and to these may be added a third sort, called vinous or inflammable spirits; which though very subtle and penetrating, are not manifestly either acid or alkaline.

All these sorts of spirits Mr. Boyle shews to be producible: and, 1. The vinous, which nature scarce ever produces of herself, are the creatures of vinous fermentation, or are actually produced, though not separated, in that operation.

2. The alkaline or volatile spirits, called also the urinous, by reason of their affinity in many qualities with spirit of urine, are manifestly not simple but compound bodies: consisting of the volatile salt of the respective concretes dissolved in the phlegm, and for the most part accompanied with a little oil: so that these may be referred to the class of volatile salts.

3. Acid spirits appear to be producible, because those drawn from common salt and nitre are very different in respect of taste, &c. from the bodies they are procured from, which are not properly acid: so that it does not appear that these spirits pre-existed in that state of those bodies.

What farther confirms this doctrine of spirits is, that the same body, merely by different ways of ordering it, may be brought to afford either acid, vinous, or urinous spirits; add, that whereas salt is accounted the principle of all taste, it follows that spirits, being sapid, must contain salt; since it is taste that characterizes and distinguishes it from phlegm, and denominates it acid, vinous, or urinous spirit.

Spirits, distilled from fermented liquors, consist of very different ingredients, viz. a pure spirit or alcohol, phlegm, a certain acetous fermented acid, and a small quantity of ill scented oil; so that it becomes necessary, in order to obtain the spirit perfectly pure, to re-distil it several times.

By reducing spirit, therefore, to the utmost degree of purity, an alcohol is obtained; which, as Dr. Shaw expresses it, is a liquor sui generis, and possessed of many peculiar qualities; as, 1. When absolutely purified, it is an uniform and homogeneous liquor, capable of no farther separation, without loss or destruction of some of its homogeneous parts. 2. It is totally inflammable, leaving no soot, nor any moisture behind. 3. It has no peculiar taste or flavour, any more than pure water, except what is owing to its nature as alcohol, or perfectly pure spirit. 4. It is an unctuous and crispy fluid, running veiny in the distillation, and its drops rolling on the surface of any other fluid, like pease upon a table, before they unite. 5. It appears to be the essential oil of the body it is obtained from broken very fine, and intimately

and strongly mixed with an aqueous fluid, which is assimilated, or changed in its nature in the operation. 6. And lastly, it seems to be a kind of universal fluid, producible with the same properties from every vegetable subject; but to produce it thus, requires some care in the operation.

On these principles is founded the opinion, that all spirits may be deduced to a perfect similarity, or sameness, from whatever subject they are produced, and on this depends their convertibility into one another; for when once they are brought to this standard of simplicity, there needs nothing more than to add the oil of such of the finer spirits as is required to convert the spirit into that particular kind. By this means the same tasteless spirit, whether obtained from malt, sugar, or grapes, may be made into either malt spirit, brandy, or rum, by adding the essential oil of the grape, sugar, or malt; and thus what was once malt spirit, shall become brandy, or whatever else the operator pleases.

Many methods have been attempted to obtain the first point, that is, the reducing the spirit to perfect and pure alcohol: the most practicable means seem to be long digestion, and the repeated distillation from water into water, where the essential oil will at once be left upon two surfaces, and the acid imbibed; the shorter ways, are those by rectifying from neutral absorbent salts and earths; such are sugar, chalk and the like; and, lastly, the use of fixed alcalies may be tried, for these very forcibly keep down both the phlegm and oil; insomuch that this last method promises to be the shortest of all, if the art were known of utterly abolishing the alkaline flavour, which the alcohol is apt to acquire.

For as vinous spirits arise with a less degree of heat than watery liquors, if due regard be had to this circumstance, very weak spirits may, by one or two wary distillations, in a degree of heat less than that in which water boils, be tolerably well freed of their aqueous phlegm: and in order to free it from its foul oil, add to every gallon of it a pound or two of pure, dry, and fixed alkaline salt; which being digested together for some time, the alkali, from its known property of attracting water and oils, will imbibe the remaining phlegm, and such part of the disagreeable unctuous matter as may be still left in the spirit, and sink with them to the bottom of the vessel. If the spirit be now again gently drawn over, it will arise entirely free from its phlegm and nauseous flavour; but as some particles of the alkaline salt are apt to be carried up with it, and give it an urinous relish, a small proportion of any fixed acid liquor, or rather of an acid salt, as vitriol or alum, should be added to it.

The spirit obtained by this process is called alcohol, and is extremely pure, limpid, perfectly flavourless, and fit for the finest purposes: it may be reduced to the strength commonly understood by proof-spirit, by mixing twenty ounces of it by weight with seventeen ounces of water. The distilled cordials made with these spirits, are much more elegant and agreeable than when the common rectified or proof spirits of the shops are made use of.

There are many occasions in which chemists, and other artificers, stand in need of the true and purest alcohol, the least remainder of water rendering the operation unsuccessful: hence it is absolutely necessary we should have some marks, by which to distinguish whether our alcohol be pure or not. The principal of these are, 1. If the supposed alcohol contains any oil dissolved in it, and so equably distributed through it, that it is no ways perceptible, then upon pouring of water into it, the mixture will grow white, and the oil separate from the alcohol. 2. If any thing of an acid lies concealed in the alcohol, a little of it mixed with the alkaline spirit of sal ammoniac will discover the acid by an effervescence excited by the affusion of the acid; for otherwise there would be only a simple coagulation. 3. If there be any thing of an alkali intermixed, it will appear by the effervescence excited by the affusion of an acid. 4. But it is a matter of great difficulty to discover whether there be any water intermixed with it. The best method of doing this is the following: take a chemical vessel with a long narrow neck, the bulb of which will hold four or six ounces of alcohol. Fill this two thirds full with the

the alcohol you intend to examine, into which throw a dram of the purest and driest salt of tartar, coming very hot out of the fire; then mix them by shaking them together, and set them over the fire till the alcohol is just ready to boil. Being thus shaken, and heated, if the salt of tartar remains perfectly dry, without the least sign of moisture, we are sure that there is no water in the alcohol. The learned Boerhaave tells us, that by this method he discovered water in alcohol which had been looked upon as pure, having undergone every other method of trial.

Medicinal Virtues of SPIRITS. The too free use of inflammable or vinous spirits, is attended with very bad effects; as the body is thereby greatly attenuated, the strength impaired, and the brain stupified. However, as Dr. Pringle justly observes, we ought not to confound the necessary and moderate use of spirits with the vice of indulging in them to excess. So far, therefore, from thinking the moderate use of spirits detrimental to soldiers, and others, who are exposed to the extremes of heat and cold, and to moist and bad air, he even recommends it; and as to soldiers in particular, he observes, that spirits, even when drank to excess, tend more to weaken the constitution than to produce any of the common camp-diseases.

Hence, in establishing messes among the soldiers, which he thinks would be attended with many good consequences, he also recommends some regulations to be made with regard to an allowance of spirits, whether by stoppages on the pay or otherwise: this he enforces by observing, that the like practice already obtains in the navy, and probably for the same reasons for which it would be proper in the army; since in ships, the men are also liable to distempers arising from moist and corrupted air. It is the abuse, therefore, of vinous spirits that ought to be condemned; since, taken in moderation, they can do no harm; and if properly accommodated to circumstances, may have very good effects.

Spirits are also of use, in external applications, to wounds and sores; as they stimulate the fluids, resist putrefaction, and quicken the pulse when absorbed. Tinctures of absorbent and aromatic powders are often prescribed with the same intention; by reason they partake of the nature of their ingredients, but principally of the spirit.

As to the volatile spirits, distilled from animal and other substances, they are in general extremely pungent and acrimonious; applied to the skin, and prevented from exhaling, they inflame the part, and produce the effect of caustics; they also liquefy the animal juices, and dissolve the coagula made from them with acids; with which being mixed, they effervesce, and unite into neutral salt. With regard to their medical virtues, they stimulate the nervous system, attenuate viscid humours, promote a diaphoresis, and other natural secretions, and absorb acidities in the primæ viæ: they are particularly useful in lethargic and apoplectic cases, in hypochondriacal and hysterical disorders, and the languors, head-achs, inflatations of the stomach, flatulent colics, and other symptoms which attend them. However, they are generally found more serviceable in aged persons, and in phlegmatic habits, than in the opposite circumstances: in febrile and inflammatory distempers, they are hurtful, except in such fevers as are accompanied with a cough, hoarseness, and redundancy of phlegm: they are most conveniently exhibited in a liquid form, largely diluted with water, or other convenient liquors; the dose being from five or six to thirty or more drops.

The acid spirits drawn from fossils, and applied to animal bodies, coagulate the fluids, and mortify the solids: by being diluted with water, they approach to the nature of vinegar. Metallic substances, dissolved in these spirits, increase their corroding sphacelating quality, so as sometimes to occasion convulsions.

SPIRITUAL, in general something belonging to, or partaking of, the nature of spirit.

The spiritual courts, in law, are such as have jurisdiction in matrimonial causes, and for probate of wills, and granting administration of goods; as also in regard to tythes, and in cases of defamation, &c.

SPIRITUALITIES of a Bishop, are the profits that he receives as a bishop, and not as a baron of parliament; such are the duties of his visitation, presentation-money, what arises from the ordination and institution of priests, the income of his jurisdiction, &c.

SPLEEN, *Lien*, in anatomy, a soft spongy viscus, situated in the left hypochondrium, under the diaphragma between the ribs and the stomach, above the left kidney. It is tied to the peritonæum, to the midriff, and to the omentum: it is of a bluish or leaden colour, of an oblong figure, thick at the edges, and not thin at the liver. It has two membranes. The external comes from the peritonæum. The internal membrane is finer and thinner than the external: for, if you blow into the splenic artery, the air shall pass through the one, but not the other. Its fibres are not irregularly woven, as those of the other membranes seem to be; but they come from innumerable points, as rays from so many centers, and the fibres of one point are regularly woven with the fibres of the point surrounding it. It receives veins, nerves, and arteries, from those that enter the spleen. The substance of the spleen is not only kept together by its two membranes, but also by innumerable fibres which come from the points of the internal membrane, and are inserted in the points of the opposite side of the same membrane: the expansion of the extremity of these fibres seems to compose the internal membrane. The spleen is composed of an infinity of membranes, which form little cells and cavities of different figures and bigness, which communicate with one another, and which are always full of blood. At the extremities of the blood-vessels in the spleens of sheep, we find several small, white, and soft specks, which Malpighi calls glands. The spleen has arteries from the cœliac, whose capillary branches make frequent anastomoses upon the membranes of the cells. Its veins, whose extremities communicate with the cavities of the cells, as they come out of the spleen, unite, and make the ramus splenicus of the vena portæ, which carries the blood from the spleen to the liver. These, with its nerves, which are considerable from the plexus splenicus, are equally distributed through the whole substance of the spleen, being all included in a common capsula. There are likewise a few lymphatic vessels which arise from the spleen, and discharge them into the lumbar glands.

The spleen, being always full of a dark-coloured blood, was by the ancients thought to be the receptacle of the atra bilis, a humour no where to be found. And all that has been said about its use by the moderns, has been to little satisfaction, till Dr. Keill taught us thus to reason thereupon.

We must consider that the bile is composed of particles, which slowly combine and unite together, and that by reason of the vicinity of the liver to the heart, and of the swift motion of the blood through the aorta, these particles could not in so small a time, and with so great a velocity, have been united together, had not the blood been brought through the coats of the stomach, intestines, and omentum, by the branches of the vena portæ, to the liver. But, because all these parts were not sufficient to receive all the blood which was necessary to be sent to the liver, therefore nature framed the spleen, into whose cavities the blood being poured from a small artery, moves at least as slowly as any that passes otherwise to the liver; by which means the particles which compose the bile in the blood which passes through the ramus splenicus, by a long and slow circulation, have more chances for uniting them; which otherwise they could not have had, had they been carried by the branches of the cœliac artery directly to the liver; and consequently without the spleen, such a quantity of bile as is now secreted, that is, as nature requires, could not have been secreted by the liver. And this he takes to be the true use of the spleen.

SPLEEN is also used for a disease by physicians more usually called the hypochondriac disease.

SPLENETIC, a person affected with oppilations and obstructions of the spleen. In splenic people, the spleen is swelled beyond the natural bulk, or hardened so as to shew a serous tumour thereon.

SPLENETIC VESSEL, a large artery and vein of the spleen.

SPLENIUS, in anatomy, a pair of the extensor muscles of the head, which rising from the lower vertebra of the neck, and the five upper ones of the back, is inserted a little above the mastoide process.

SPLINT, or **SPLINT**, among farriers, a callous, insensible excrescence, breeding on the shank-bone of horses; which, when it grows big, spoils the shape of the leg, and generally comes upon the inside: but if there be one opposite to it on the outside, it is called a peg, or pinned splint; because it does, as it were, pierce the bone, and is extremely dangerous.

The simple splints are only fastened to the bone, at a pretty distance from the knee, and without touching the back sinew, and have not a very bad consequence; but those that touch the back sinew, or are spread on the knee, will make a horse lame in a short time.

For the cure of this malady, shave away the hair, and rub and beat the swelling with the handle of a shoeing hammer; then having burnt three or four hazle-sticks, while the sap is in them, chafe the splint with the juice, or water that issues out at both ends, applying it as hot as you can, without scalding the part: after that, rub or bruise the swelling with one of the sticks, and continue frequently to throw the hot juice upon the part, but so as not to scald it, and continue still rubbing it, till it grows soft. Then dip a linnen cloth, five or six times double, in the hazle-juice, as hot as your hands can endure it, and tie it upon the splint, where let it remain for twenty-four hours, keeping the horse in the stable for the space of nine days, not suffering him to be either ridden or led to water; by which time, the splint will be dissolved, and the hair will afterwards grow on it again.

SPLENTS, or **SPLINTS**, in surgery, pieces of wood, used in binding up broken limbs.

SPLINTER, a small shiver of wood, or the like. The splinters of fractured bones, if loose, are to be carefully removed, otherwise replaced.

SPODIUM, in pharmacy, one of the foulest recrements of copper; being nothing but the worst and heaviest parts of the cadmia ostracitis, thrown up in such coarse pieces by the blast of the bellows, that it does not adhere to the roof or sides of the furnace, but falls down again into several parts of the furnace; and being collected along with many other kinds of foulnesses, in form of a blackish heavy matter, is indeed no better than the sweepings of the furnaces, where the copper is refined.

SPOILS, *Spolia*, whatever is taken from the enemy, in time of war.

Among the ancient Greeks, the spoils were divided in common among the whole army, only the general's share was largest; but among the Romans, the spoils belonged to the Republic.

SPONDEE, in the Greek and Latin prosody, a foot of verse consisting of two long syllables:— as *vērtūt*.

SPONDYLUS, in anatomy, a name anciently given to a vertebra of the spina dorsa.

SPONGIA, *Sponge*, in botany, &c. See the article **SPUNGE**.

SPONGIOSA, in anatomy, an epithet given to several parts of the body by reason of this texture, which is porous and cavernous, like that of a sponge.

SPONSORS, among Christians, are those persons, who, in the office of baptism, answer, or are sureties, for the persons baptised.

In the ancient church, there were three sorts of sponsors: 1. For children, who could not answer for themselves; and in most cases, parents were sponsors for their own children. 2. For such persons as, by reason of sickness or infirmity, were in the same condition with children; who might be baptized, if their friends testified, that they had before-hand desired baptism, and at the same time became their sponsors. 3. For all adult persons in general; for these too had their sponsors, as no persons were baptised without them.

It is observable, that anciently no more than one sponsor was required, namely, a man for a man, and a

woman for a woman: however, in the case of infants, no regard was had to the difference of sex; for a virgin might be sponsor for a male child; and a father for his children, whether male or female.

In the modern Christian church, the office of sponsors, or sureties in baptism, is better known than practised; we call them god-fathers and god-mothers.

SPONTANEOUS, in the schools, is a term applied to such motions of the body and mind as we perform of ourselves, without constraint.

The word is formed from the Latin adverb *sponte*, of one's own accord.

SPORADES, among antient astronomers, a name given to such stars as were not included in any constellation.

SPORADIC, is used for such diseases as reign in the same place and time.

SPOTS, in astronomy, certain places of the sun's or moon's disc, observed to be either more bright, or darker, than the rest, and accordingly, called *faculae* and *maculae*.

SPOUT, or **WATER-SPOUT**, in natural history, an extraordinary and dangerous meteor, observed at sea, and sometimes at land, called by the Latins, *typho* and *sipho*. Its first appearance is in form of a deep cloud, the upper part of which is white, and the lower black: then from the lower part of this cloud hangs, or rather falls down, what is properly called the spout, in form of a conical tube, biggest at top; and under this tube there is always a great boiling and flying up of the water of the sea, as in a *jet d'eau*. For some yards above the surface of the sea, the water stands as a column or pillar, from the extremity of which it spreads and goes off, as in a kind of smoke. Frequently, the cone descends so low, as to touch the middle of this column, and continue for some time contiguous to it; though sometimes it only points to it, at some distance, either in a perpendicular or oblique line. Frequently it is scarce distinguishable, whether the cone or the column appear the first, both appearing all of a sudden against each other. But sometimes the water boils up from the sea to a great height, without any appearance of a spout pointing to it, either perpendicularly or obliquely. Indeed, generally, the boiling or flying up of the water has the priority, this always preceding its being formed into a column. Generally, the cone does not appear hollow, till towards the end, when the sea-water is violently thrown up along its middle, as smoke up a chimney. Soon after this, the spout or canal breaks and disappears; the boiling up of the water, and even the pillar, continuing to the last, and for some time afterwards; sometimes till the spout form itself again, and appear a-new; which it sometimes does several times in a quarter of an hour. See plate CXXII. fig. 7.

M. de la Pyme, from a near observation of two or three spouts in Yorkshire, described in the Philosophical Transactions, gathers that the water-spout is nothing but a gyration of clouds by contrary winds, meeting in a point or center; and there, where the greatest condensation and gravitation is, falling down into a pipe or great tube, somewhat like Archimedes's spiral screw; and, in its working and whirling motion, absorbing and raising the water, in the same manner as the spiral screw does; and thus destroying ships, &c. Thus, June the 21st, he observed the clouds mightily agitated above and driven together; upon which they became very black, and were hurried round, whence proceeded a most audible whirling noise, like that ordinarily heard in a mill. Soon after, issued a long tube or spout, from the center of the congregated clouds, wherein he observed a spiral motion like that of a screw; by which the water was raised up. Again, August 15, 1687, the wind blowing at the same time out of several quarters, created a great vortex and whirling among the clouds; the center whereof, every now and then, dropped down, in shape of a long, thin, black pipe, wherein he could distinctly behold a motion like that of a screw, continually drawing upwards, and screwing up, as it were, wherever it touched. In its progress it moved slowly over a grove of trees, which bent under it like wands in a circular motion.

tion. Proceeding it tore off the thatch from a barn, bent a huge oak-tree, broke one of its greatest branches, and threw it to a great distance. He adds, that, whereas it is commonly said, the water works and rises in a column, before the tube comes to touch it; this is doubtless a mistake, owing to the fineness and transparency of the tubes, which do most certainly touch the surface of the sea, before any considerable motion can be raised therein; but which do not become opaque and visible, till after they have imbibed a considerable quantity of water.

The dissolution of water-spouts he ascribes to the great quantity of water they have glutted; which by its weight impeding their motion, whereon their force, and even existence, depends, they break and let go their contents; which use to prove fatal to whatever is found underneath. A notable instance hereof we have in the Philosophical Transactions, related by Dr. Richardson; for a spout in 1718 breaking on Emott-moor, nigh Coln, in Lancashire, the country was immediately overflowed.

In Pliny's time, the seamen used to pour vinegar into the sea, to assuage and lay the spout, when it approached them: our modern seamen keep it off, by making a noise with filing and scratching violently on the deck, or by discharging great guns to disperse it.

SPRING, Fons, in natural history, a fountain or source of water arising out of the ground.

The origin of springs, or fountains, is a thing greatly controverted among naturalists. There are however but three hypotheses of any tolerable repute relating to this question: all others, it is allowed by every philosopher, are not worth mentioning, much less the trouble of confuting.

The first hypothesis is that of Des Cartes, who was of opinion, that the water of the sea diffused itself in all directions under ground, and that, coming to the bottom of mountains, it there met with large caverns, into which, being rarified by the central heat beneath, it ascended in vapours, leaving its saline parts behind, as being superficially heavier; that these vapours, being impeded in their ascent by the tops of the caverns, condensed there, forming little streams of currents of water, like the steam in the head of an alembic.

But this hypothesis is far from being agreeable to truth; for, in the first place, it is begging the question to suppose any such free passages of communication betwixt the sea and the bases of mountains; nor can any experiment be produced to warrant the supposition of these subterraneous channels; on the contrary, wherever running waters have been discovered in the bowels of the earth, it has been observed, that they run the contrary way, viz. from the mountains to the sea.

But let us grant that the waters have a free passage from the sea, for two or three hundred leagues, to the bases of high mountains; where are the furnaces which remain in such a constant state of readiness and heat, to rarify these waters, and make them evaporate in clouds? But let us still farther allow, that there is a sufficient degree of heat for this purpose; yet where are those caverns six or seven hundred paces high, whose cool vaults are to condense these exhaled vapours? It is certain that people have digged and penetrated far enough into the bowels of the earth and mountains, to make the discovery, but without ever finding caverns big enough to allow the vapours a free ascent to the height of the fountains, from whence the rivers derive their source. Besides, a concurrence of all these vapours could not produce the least stream of fresh water; for the vapours adhering to the side of the caverns, and there condensing, not finding any receptacle to receive them, and from whence they might issue out through the sides in springs, must consequently fall down again into the basin from whence they arose: so that these wonderful alembics, with which Des Cartes seems so highly delighted, are only mere fancies, having no existence in nature.

The second hypothesis supposes that the sea-water percolates through the pores of the earth, which, though large enough for the fluid to penetrate, yet are so small as to deny admittance to the saline particles which are commixed with them; which the water, during

the course of its filtration, leaves behind, thus refining and purifying itself, till it becomes fresh and potable, before it mixes with the fountains and rivers.

But this hypothesis is no less absurd than the former; for, what can become of the salt which so many rivers must have deposited under ground? It is now about six thousand years that the sea, according to this hypothesis, has been distributing out its waters and salts to the source of rivers, without having received in return from them any other than fresh water; and consequently it would have happened, by degrees, either that the sea must have emptied itself of all its salts, or the earth have been so overcharged with them, as that these salts would have blocked up those subterraneous channels the water should pass through, in order to supply the fountains.

It has been found by repeated experiments, that a pound of salt-water will yield four drams of salt, and consequently a cubic foot of water, which weighs near seventy pounds, will produce three pounds of salt; but, that our calculation may be allowed moderate and unexceptionable, we will say only two pounds. Now the celebrated Dr. Halley, by an unexceptionable calculation, found that the quantity of water which passes daily thro' the Thames, is above 76,032,000 cubic feet; and consequently the quantity of salt daily deposited in the bowels of the earth, before it arrives to the sources of that river, must be 152,064,000 pounds, or above 678,857 tons. We have hitherto taken out but one river into our account; but, if we add those of the whole earth, what prodigious quantities of salt must be daily amassed in the bowels of the earth! A few years will be sufficient to render those masses bigger than the mountains themselves, and the earth must constantly increase and swell with these additional supplies of matter.

The third hypothesis owes its origin to that sagacious naturalist, Dr. Edmund Halley, and is as follows: It is evident from experience, that there perpetually arises a vapour from the surface of the sea, rivers, and lakes; this vapour is carried through the atmosphere in the form of a cloud or mist, by the impulse of winds; and, according as it meets with a colder air, or is stopped in its progress by mountains, it condenses, and falls down in dew, snow, or rain; the water, in whichever of these shapes it descends, finds several chinks and crannies, through which it insinuates itself into the main body of the hills or mountains, where it is lodged in beds of stone or clay, according to the nature of the soil; and by degrees, increasing its store and strength, it forces its way through the first outlet it meets with, and takes the name of a temporal or perennial fountain, according to the capacity of the basin, which supplies its current.

This beautiful hypothesis, which has been received with universal applause and satisfaction by the learned world, we shall endeavour to demonstrate, by the two following propositions: 1. That the vapours which arise from the sea, are much more than sufficient to supply both the surface of the earth and the rivers with water. 2. That the mountains do, by their particular structure and formation, attract, and, as it were, arrest the vapours and the rain that fluctuate about in the atmosphere: and, having collected them in their reservoirs, dismiss them again through their sides, either in perpetual or intermitting currents.

With regard to the first, the ingenious author of this theory made the following experiment: he took a vessel of water, and made of the same degree of saltiness with that of the sea, by means of the hydrometer; and having placed a thermometer in it, he brought it, by means of a pan of coals, to the same degree of heat with that of the air in the hottest summer. He then placed this vessel with the thermometer in it, in one scale, and nicely counterpoised it with weights in the other; after two hours, he found, that about the sixtieth part of an inch was gone off in vapour, and consequently in twelve hours, the length of a natural day, one tenth of an inch would have been evaporated.

From this experiment it follows, that every ten square inches of the surface of the water yield a cubic inch of water in vapour per day, every square mile 6914 tons, and every square degree (or 69 English miles) 33 millions of tons. Now, if we suppose the Mediterranean

to be 40 degrees long, and 4 broad, at a medium, which is the least that can be supposed, its surface will be 160 square degrees, from whence there will evaporate 5280 millions of tons per day, in the summer-time.

The Mediterranean receives water from the nine great rivers following, viz. the Iberus, the Rhine, the Tyber, the Po, the Danube, the Neister, the Borysthenes, the Tanais, and the Nile; all the rest being small, and their water inconsiderable. Now let us suppose that each of these rivers conveys ten times as much water to the sea as the Thames; which, as is observed, yields daily 76,032,000 cubic feet, which is equal to 203 millions of tons; and therefore all the nine rivers will produce 1827 millions of tons; which is little more than one third of the quantity evaporated each day from the sea. The prodigious quantity of water remaining, the doctor allows to rains, which fall again into the seas, and for the uses of vegetation, &c.

As to the manner in which these waters are collected, so as to form reservoirs for the different kinds of springs, it seems to be this: the tops of mountains, in general, abound with cavities, and subterraneous caverns formed by nature to serve as reservoirs; and their pointed summits, which seem to pierce the clouds, stop those vapours which fluctuate in the atmosphere, and being constipated thereby, they precipitate in water, and by their gravity easily penetrate through beds of sand and lighter earth, till they are stopped in their descent by more dense strata, as beds of clay, stone, &c. where they form a basin or cavern, and work a passage horizontally, and issue out at the side of the mountain.

Many of these springs running down by the vallies, between the ridges of hills, and uniting their streams, form rivulets or brooks; and many of these again, uniting on the plain, become a river.

In order to account for the different sorts of springs, let A B C D E (plate CXXII. fig. 8.) represent the declivity of a hill, whose section, from top to bottom, is shewn in the figure; in which let F G H be a cavern or basin near the top, which collects the water gleeting through the strata, and has a drain or duct leading to the side of the hill at B. It is evident, that, when the water arises to the drain H, it will descend through it to B, where it will break out in form of a fountain or spring, and will continue running while the reservoir is supplied with water above the level F H, and after that it will become dry. Hence we see that a spring may be formed near the tops of the highest mountains and hills; but on the very tops, it is impossible for them to be generated.

Intermitting springs, or those which flow and stop by regular alterations and intermissions, may be thus accounted for: let I K L represent a cavity in the mountain, to which, at I, there is a feeding stream which brings the water from other parts; and at K, on the lower part, there goes a duct K k C, of a curved or crooked form, which conveys the water to the side of a hill at C, where it breaks out into a spring. Now, it is evident, that, as the water rises in the cavern, it will also rise in the duct, till the surface of the water I L be level with the highest part k of the duct, and then the water will descend from k to C, which point, being lower than the orifice of the duct at K, will exhaust the cavern of all its water, and the spring will stop, till the cistern is replenished to the same level I L, by the feeding stream I, and then the fountain will play again. An artificial fountain of this kind may be also easily made.

Reciprocating SPRINGS, or those which flow and ebb alternately, are occasioned in the following manner. Let A B C D (fig. 9.) represent a reservoir, fed by the stream O, whose water flows into another reservoir I K L, through the syphon M N, and at the same time has another stream at W, falling into the same reservoir, whose outlet or spring is at Y. This spring will reciprocate, or flow and ebb; for, when the syphon M N works, the surface of the water at Y will be suddenly raised, and press upon the water at K, with a greater force, and consequently it will issue out with a greater velocity, and raise the surface, if confined; but, when the syphon intermits, the momentum will be less, and then the stream will ebb or decrease. This may also be

understood from fig. 10. where M N O represents the reservoir, which is fed both by the stream M, and also by that at O, when the spring at C works, and D the out-let or fountain; for when the spring at C works, the spring at D will flow or increase; but, when that at C intermits, the other at D will ebb.

Medicinal Virtues, &c. of SPRINGS. These are owing to the different qualities and temperament of the strata through which these waters may be collected, or pass: if those reservoirs of water in the body of mountains be situated where mineral ores abound, or the ducts and feeding streams run through mineral earths, it is easy to conceive that particles of metal will mix with, and be absorbed by the water, which being saturated therewith, becomes a mineral spring or well. If salt, sulphur, lime-stone, &c. abounds in the strata, through which the water passes, it will then be saline, sulphureous, lime-water, &c. If sulphur and iron should both abound in the parts of the hill, whence the waters come, the waters will partake of the warmth or heat which is occasioned by the mixture of two such substances in the earth, where they are found.

SPRING, Ver, in cosmography, implies one of the seasons of the year; commencing, in the northern parts of the world, on the day the sun enters the first degree of Aries, which is about the twenty-first of March, and ending when the sun leaves Gemini.

SPRING, Elator, in mechanics, denotes a thin piece of tempered steel, or other elastic substance; which, being wound up, serves to put several machines in motion by its elasticity, or endeavour to unbend itself: such is the spring of a clock, watch, and the like.

The spring of a lock, gun, pistol, or the like, is a piece of steel, violently bent; which, being set at liberty, beats back the bolt of the lock, or strikes down the cock.

SPRING-TIDE. See the article *TIDE*.

SPRINGY BODIES, the same with elastic ones; or such as, having had their figure changed by the stroke of another body, can recover again their former figure, which bodies not elastic cannot do.

SPONGE, in natural history, a plant of so very singular a structure, that many authors have supposed it not merely a vegetable, but of an intermediate nature between that and the animal kind, and have ranked it among the number of an imaginary race of beings, which they call zoophytes. Sponge, however, is a genuine plant; nor is there in the creation any such class of beings as zoophytes, or any creature that is partly plant, partly animal.

We meet with sponges, in the shops, often in the whole plant; sometimes only in pieces of larger ones; in either case, it is of a perfectly irregular figure, and is only to be distinguished by its texture, which is cavernous, like that of a honey-comb; its elasticity, which makes it, after passing into a very small compass, immediately expand to its full bulk again, on taking away the pressure; and by its property of imbibing, perfectly, a large quantity of water, and as readily parting with it again, on squeezing.

Sponge is to be chosen perfectly clean, and free from stones within, or from a crustaceous and hard matter without; of as pale a colour as may be, and with small holes, and such as is lightest.

The greatest part of the sponge we use, is brought from Aleppo and Smyrna. It grows in the Archipelago, at considerable depths, on the rocks about some of the islands there, and multitudes of people make a trade of diving for it. It is also common in the Mediterranean and many other seas, though in general, browner or yellower, and not so fine as that of the Archipelago.

It grows in large masses to rocks and stones, sometimes to large shells; and is sometimes round, sometimes flat, sometimes hollow, like a funnel. It is one of the cryptogamiæ of Linnæus, one of the herbæ marinæ of Tournefort, and one of the herbæ imperfectæ of Mr. Ray. It is described by all the botanical writers, under the name of *spongia marina alba*, and *spongia globosa*, the white or round sponge. Distilled by a retort, it yields a large quantity of white milky phlegm, of a fishy smell; after this a large portion of an urinous

reddish liquor, with a little of a dry, volatile, urinous salt, and a thick, brownish, foetid oil. The remainder, in the retort, yields only a small portion of a lixivial salt, and that not merely alkaline.

Sponge calcined to a blackness, and reduced to powder, has been lately brought into great use as a sweetner of the blood, and a diuretic: some have pretended even to cure leprosy with it, and others have extolled it against the bite of a mad dog; but these are virtues less certainly known of it.

In the larger and coarser pieces of sponge, there are often small stones found imbedded in the substance of the matter; and yet, more frequently, a crustaceous sparry matter gathered round the surface of certain parts of the plants; both these substances are called by the common name of lapis spongiæ, the sponge-stone; and both are recommended as diuretics, and remedies against the stone and gravel. See SPAR.

Pyrotechnical SPUNGES are made of the large fungous excrescences growing on old oaks, ashes, fir, &c. which being boiled in common water, then dried and well beaten, are put in a strong ley prepared with salt-petre, and again dried in an oven. These make the black match or tinder brought from Germany, used to receive and sustain the fire struck from a flint and steel, &c.

SPUNGE is also used, in gunnery, for a long staff or rammer with a piece of sheep or lamb-skin wound about its end, to serve for scouring great guns, when discharged, before they are charged with fresh powder.

SPUNGE of a Horse-shoe, the part next the heel, where the calkins are made.

SPUNGING, in gunnery, the cleaning a gun's inside with a sponge, in order to prevent any sparks of fire from remaining in her, which would endanger the life of him who should load her again.

SPUR, a piece of metal, consisting of two branches encompassing a horseman's heel, and a rowel in form of a star, advancing out behind, to prick the horse.

SPURIOUS DISEASES, such as, in some symptoms, cannot be reduced to any one kind; and, therefore, are denominated from those with which they agree in most particulars: thus we say, a spurious or bastard pleurisy, quinzy, &c.

SPY, a person hired to watch the actions, motions, &c. of another; particularly of what passes in a camp. When a spy is discovered, he is hanged immediately.

SQUADRON, in military affairs, denotes a body of horse whose number of men is not fixed: but is usually from one to two hundred.

Each squadron usually consists of three troops of fifty men each.

SQUADRON of Ships, a division or part of a fleet, commanded by a vice-admiral, or commodore.

SQUALUS, the SHARK-KIND, in ichthyology, a numerous genus of fishes, of the chondropterygious order; the characters of which are these: the foramina of the gills are five on each side, and are situated in a longitudinal direction, from the sides of the head down to the pectoral fins; the head is of a depressed form; the body is oblong, and is either rounded or angulated, and the skin is rough; the eyes stand on the sides of the head; the tail is bifid; and the upper part longer than the under; the mouth is usually transverse, and in the under part of the rostrum, not at its extremity.

The species of this genus being very numerous, are arranged under the following subdivisions. 1. Those which have granulated-teeth, as the saw-fish, and the smooth hound-fish. 2. Those which have acute teeth, and prickles on the back; as the common hound-fish, the shagreen-fish, centrine and monk-fish. 3. Those which have acute teeth, but no spines or prickles on the back; as the zygæna, or ballance-fish, the sea-fox, and the tope. 4. Those which have the rostrum shorter than usual; as the bounce, morgag, and blue and white sharks.

SQUAMOUS, or SQUAMOSE, in anatomy, an appellation given to the spurious or false sutures of the skull, because composed of squamæ or scales like those of fishes, or like tiles laid so as to reach over one another.

SQUARE, *Quadratum*, in geometry, a quadrilateral figure, both equilateral and equiangular.

To find the area of a square, seek the length of one side; multiply this by itself, and the product is the area of the square.

SQUARE NUMBER, the product of a number multiplied into itself.

Thus 4, the product of 2 multiplied by 2; or 16, the product of 4 multiplied by 4; are square numbers.

SQUARE ROOT, a number considered as the root of a second power or square number; or a number by whose multiplication into itself, a square number is generated.

SQUARE-BATTLE, or BATTALION of Men, is one that hath an equal number of men in rank and file.

Hollow SQUARE, in the military art, is a body of foot drawn up with an empty space in the middle for the colours, drums, and baggage; faced and covered by the pikes every way, to keep off horse.

SQUARE, *Norma*, an instrument consisting of two rulers, or branches, fastened perpendicularly at one end of the extremes, so as to form a right angle: it is of great use in the description and mensuration of right angles, and laying down perpendiculars.

SQUATT, among miners, a small bed of ore less valuable than a vein or load, as reaching only a little way.

SQUINANCY, or ESQUINANCY, in medicine, the same with the quinzy. See QUINZY.

SQUINTING, *Strabismus*, in medicine and surgery. See the article STRABISMUS.

SQUIRREL, *Sciurus*, in zoology, the English name of a genus of quadrupeds of the order of the glires, the fore-teeth of which are prominent; it has no canine teeth; and its legs are formed both for climbing and leaping.

The common reddish-brown squirrel, with a white belly, is a very lively little animal, with an extremely long and bushy tail.

But besides this, there are several other species; as the American grey-squirrel, with a smaller tail, and twice as large as the common kind; the Ceylon blackish squirrel, with a very large tail, and about the size of the common squirrel; the flying-squirrel, with the sides extended, so as to be able to leap from one tree to another at a great distance; and, lastly, the Barbary squirrel, of a blackish tawny-brown colour, with variegated sides.

STABLE, a place or house for horses, &c. furnished with stalls and proper apartments to contain their food, &c.

Nothing conduces more to the health of a horse than the having a good and wholesome stable. The situation of a stable should always be in a good air, and on a firm, dry, and hard ground, that in winter the horse may go out and come in clean. It should always be built somewhat on an ascent, that the urine and other foulnesses may be easily conveyed away by means of trenches or sinks for that purpose. As there is no animal that delights more in cleanliness than the horse, or that more abominates bad smells, care should be taken that there be no hen-roost, hog-stie, or necessary-house, near the place where the stable is to be built; for the swallowing of feathers, which is very apt to happen, when hen-roosts are near, often proves mortal to horses; and the steams of a bog-house, or hog's-dung, will breed many distempers. The walls of a stable, which ought to be of brick rather than stone, should be made of a moderate thickness, two bricks, or a brick and a half at least, for the sake of warmth in the winter, and to keep out the heat in the summer. The windows should be made on the east and north side of the building, that the north wind may be let in to cool the stables in the summer, and the rising sun all the year round, especially in winter. The windows should either be sashed, or have large casements, for the sake of letting in air enough; and there should always be close wooden shutters, that the light may be shut out at pleasure, by which means the horse may be made to sleep in the day as well as in the night, when it is judged proper he should do so. Many pave the whole stable with stone, but that part which the horse is to lie on should be boarded with oak planks,

D d d

which

which should be laid as even as possible, and cross-wise rather than length-wise; and there should be several holes bored through them to receive the urine, and carry it off underneath the floor into one common receptacle; the ground behind should be raised to a level with the planks, and it should be paved with small pebbles. There are two rings to be placed on each side of the stall, for the horse's halter to run through, and a logger is to be fixed to the end of this sufficient to poise it perpendicularly, but not so heavy as to tire the horse, or to hinder him from eating; the best place for him to eat his corn in is a drawer or locker, made in the wainscot partition, which need not be large, so that it may be taken out at pleasure to clean it, by which means the common dirtiness of a fixed manger may be avoided. Many people are against having a rack in their stables; they give the horse his hay sprinkled upon his litter, and if they think he treads it too much, they only nail up three or four boards, by way of a trough, to give it to him in: the reason of this is, that the continual lifting up of the head to feed out of the rack, is an unnatural posture for a horse, who was intended to take his food up from the ground, and makes him, as they express it, with-cragged. When there is stable-room enough, partitions are to be made for several horses to stand in; these should always allow room sufficient for the horse to turn about and lie down conveniently, and they should be boarded up so high towards the head, that the horses placed in separate stalls may not be able to smell at one another, nor molest each other any way. One of these stalls ought to be covered in, and made convenient for the groom to lie in, in case of a match, or the sickness of a horse. Behind the horses there should be a row of pegs, to hang up saddles, bridles, and other utensils; and some shelves for the brushes, pots of ointment, &c. The other requisites for a stable are a dung-yard, a pump, and a conduit.

STACK of Wood, among husbandmen, is a pile of three feet long, as many broad, and twelve feet high.

STADIUM, an antient Greek long measure, containing 125 geometrical paces, or 625 Roman feet, corresponding to our furlong.

The word is formed from the Greek *στασις*, station; and it is said, on this occasion, that Hercules, after running so far at one breath, stood still. The Greeks measured all their distances by stadia, which they call *stadia*.

STADTHOLDER, **STADTHOULDER**, or **STAT-HOLDER**, a governor or lieutenant of a province in the United Netherlands; particularly that of Holland; where the word is most used by reason of the superior importance of the government of that province.

Menage derives the word from *stadt*, state, and *houder*, holding, q. d. lieutenant of the states: others will have it compounded of *stad*, or *stede*, stead, or place, and *houder*, holding; in regard this officer held the place of the counts, and represented them in their absence.

The stadtholder, that is, the stadtholder of Holland is the first member of the republic; he is chief of all the courts of justice, and may preside therein when he pleases. All sentences, judgments, &c. are dispatched in his name.

—When an office becomes vacant in any of the courts, the states propose three persons to the stadtholder, who is to choose one of them.

He can even pardon criminals, which is a sovereign prerogative, and has the choice of scabines, or chief magistrates in each city, to which end the council of the city present him two persons, one of which he appoints.

STAFF, in music, five lines on which, with the intermediate spaces, the notes of any song or piece of music are marked.

STAFF, in surveying, a kind of stand whereon to mount a theodolite, circumferentor, plain table, or the like, for use. It consists of three legs of wood joined together at one end, whereon the instrument is placed, and made sharp at the other to enter the ground. Its upper end is usually fitted with a ball and socket.

STAG, in zoology, a very stately and beautiful animal. People are apt to confound it with the common fallow deer, but with great impropriety, being of twice

the size, and different in many other respects: the head is remarkably large; the neck strong and thick; the eyes are full and large; the ears long and patulous; the horns tall, almost erect, and of a beautiful form; they rise each with a single and elegant stem, which continues its form to the top, only sending off branches and divarications: they are hairy when first formed, but afterwards they become very strong, and lose that downy appearance. The body of the stag is round and plump, the back somewhat flattened, and the belly prominent: the legs are long, the hoofs cloven, the fur deep, thick, and of a tawny reddish colour.

STAGE, in the modern drama, the place of action and representation, included between the pit and the scenes, and answering to the proscenium, or pulpitum, of the ancients.

The laws of the stage are the rules and decorums to be observed, with regard to the oeconomy and conduct of a dramatic performance to be exhibited on the stage. These relate principally to the unities, the disposition of the acts and scenes, the unravelling, &c.

STAGGERS, or **STAVERS**, in farriery. See the article **STAVERS**.

STAIR-CASE, in architecture, the ascent inclosed between walls, or a balustrade, consisting of stairs, or steps, with landing places and rails, serving to make a communication between the several stories of a house.

The construction of a complete stair-case is one of the most curious works in architecture. The common rules to be observed therein are as follows: 1. That it have a full free light to prevent accidents of slipping, falling, &c. 2. That the space over-head be large and airy, which the Italians call *un bel sfocato*, i. e. good ventilation, in regard a man spends much breath in mounting. 3. That the half paces, or landing-places, be conveniently distributed for repassing in the way. 4. That to prevent rencounters, &c. the stair-case be not too narrow: however, this last is to be regulated by the quality of the building. 5. That care be taken in placing the stair-case, so as the stairs may be distributed without prejudice to the rest of the building.

The kinds of stair-cases are various: in some the stairs are straight, in others winding, in others both ways, or mixed. Again, of straight stairs, called also fliers; some fly directly forwards, others are square, others triangular, and others are called French flights. Of winding-stairs, called also spiral or cockle-stairs; some are square, some circular, and some elliptical: and these again are various; some winding round a solid, and others round an open newel. Lastly, of mixed stairs; some are called dog-legged, others both wind about a solid newel, and fly about a square open newel.

Stair-cases being of great importance in building, it will be necessary to give a particular account of each kind. First, straight-stairs are such as always fly; that is, proceed in a right line, and never wind; whence their denomination. Of these there are several kinds, as, 1. Straight-fliers, or plain fliers, which proceed directly from one floor to another, without turning either to the right or left: these are seldom used, except either for garret or cellar stairs. 2. Square-fliers, which fly round the sides of a square newel, either solid or open, having at every corner of the newel a square half step, taking up one fourth of a circle, so that they fly from one half pace, or step, to another; and the length of the stairs is perpendicular to the side of the newel. 3. Triangular fliers are those which fly round by the sides of a triangular newel, either solid or open, having at each corner of the newel a trapezial half-step, taking up two thirds of a circle, so that they fly from one half step to another, and their length is perpendicular to the side of the newel. 4. French fliers, those which fly first directly forwards, till they come within the length of a stair of the wall, and then have a square half-pace, from which you immediately ascend to another half-pace, from which the stairs fly directly back again, parallel to their first flight.

Secondly, Winding-stairs are such as always wind and never fly: of these there is great variety; as, 1. Circular winding stairs; of which there are four kinds, viz. such as wind about a solid newel, the fore-edge of each

each being in a right line, pointing to the center of a newel; commonly used in church-steeple and great old houses: such as wind round an open newel, the fore-side of each being in a right line, pointing to the center of the newel, as those in the Monument of London: such as wind round a solid newel, only the fore-side of each an arch of a circle, either concave or convex, pointing near to the circumference of the newel, and such as resemble the last in all other respects, save that they have an open newel. Any of these winding-stairs take up less room than the other kinds. In stairs that wind round a solid newel, architects make the diameter of the newel either one sixth, or one fourth, or one third, or three sevenths, of the diameter of the stair-case, according as that is in bigness: if very small, the newel is but one sixth; and, if large, three sevenths, &c. In stairs that wind round an open newel, Palladio orders the newel to be one half of the diameter of the stair-case, though there does not appear any reason why the newel here should not be proportioned to the stair-case, as in the former. As to the number of stairs in each revolution, Palladio orders, that if the stair-case be six or seven feet diameter, the stairs in each revolution to be twelve; if the diameter be eight, the stairs to be sixteen; or if nine or ten, the stairs to be twenty; and if eighteen, to be twenty-four. 2. Elliptical winding-stairs, whereof there are two kinds, the one winding round a solid, the other round an open newel: they are much of the same nature with circular stairs, excepting that in the one the newel is a circle, and in the other an ellipsis. 3. Square winding-stairs are such as wind round a square newel, either solid or open, the fore-side of each stair being a right line pointing to the center of the newel. 4. Triangular winding-stairs are such as wind round a triangular newel, the fore-side of each being a right line pointing to the center of the newel. 5. Columniated winding-stairs. Palladio mentions a stair-case in Pompey's portico, at Rome, set on columns, so as the light they receive from above may distribute itself to all parts alike. 6. Double winding-stairs. Scamozzi mentions a stair-case in this form made by Piedro del Bergo and Jean Coffin, at Sciamburg, in France, in the king's palace. It is so contrived, that the one ascending and the other descending, shall never meet. Dr. Grew describes a model of this kind of stair-case kept in the Musæum of the Royal Society. The foot of one of the stair-cases, he says, is opposite to that of the other, and both make a parallel ascent, and within the same cylinder: the newel in the middle is hollow, and built with long apertures, to convey light from candles placed at bottom, and at the sides of the newel, in both cases. 7. Quadruple winding-stairs. Palladio mentions a stair-case of this form in the castle of Chambor, near Blois. It consists of four stair-cases, carried up together, having each its several entrance, and going up one over another in such a manner as that being in the middle of the building, the four serve to lead to four apartments, so that the people of the one need not go up and down the stairs of the other; yet being open in the middle, they all see each other pass.

Thirdly, mixed-stairs are such as partly fly and partly wind; whence some call them fliers and winders. Of these there are several kinds: as, 1. Dog-legged-stairs, which first fly directly forwards, then wind a semi-circle, and then fly directly backwards parallel to that. 2. Square-fliers and winders have a square newel, either solid or open, and fly by the sides of the newel, winding a quadrant of a circle at each corner. 3. Solid and open newelled fliers and winders are of two kinds: the one winds the quadrant of a circle about a solid newel, then flies by the side of a square open newel, then winds again by the side of a solid newel, then flies again as before, and so alternately. The other flies first, then winds, then flies again, alternately.

The dimensions of stairs are differently assigned by different authors; but, however, they agree in this, that they must not be more than six, nor less than four inches high; nor more than eighteen, nor less than twelve inches broad: nor more than sixteen, nor less than six feet long, each stair. But these measures regard only large and sumptuous buildings; for in common and

ordinary houses, they may be something higher and narrower, and much shorter; yet even in these the stairs are not to exceed seven, or at most eight inches in height, nor be less than nine or ten inches in breadth; nor three feet in length. To reduce the dimensions of stairs to some natural, or at least geometrical, standard, Vitruvius borrows the proportion of the sides of a rectangled triangle, which the ancient school expressed by the numbers 3, 4, and 5; the first for the perpendicular height, from the stair-head to the ground; the second for the horizontal breadth; and the third for the whole slope, or inclination, from the edge of one stair to that of another. But this rule is laid aside, and with good reason, by the modern builders; for on this principle, the lower the stairs, the narrower they must be; and stairs, for instance, four inches high, such as we find mentioned by ancient architects, must be but five inches and one third broad.

One rule to be regarded in the making of stairs is, that they be laid somewhat sloping, or a little higher behind, that the foot may, as it were, both ascend and descend at the same time; which, though it is observed by few, is found a secret and delicate deception of the pains in mounting.

STAKE, the name of a small anvil, used by smiths; sometimes it stands on a broad iron-foot on the work-bench, to be moved up and down occasionally; and sometimes it hath a strong iron-spike at the bottom, by which it is fixed to some place on the work-bench: Its use is to set small and cold work straight, by hammering it on the stake; or to cut or punch upon the cold chisel or cold punch.

STALACTITÆ, or STALACTAGNIA, STONY ICICLES, in natural history, crystalline spars formed into oblong, conical, round, or irregular bodies, composed of various crusts, and usually found hanging in form of icicles from the roofs of grottos, &c.

Of this class there are various species, as the hard, white stalactitæ; the white, shattery stalactitæ; and the yellow shattery crystalline stalactitæ, &c.

STALK, in botany, the stem or stock of a plant. Stalks are distinguished into several kinds, viz. the naked stalk, which has no leaves on; crested stalk, which has furrows, or ridges, winged stalk, which has leaves on both sides; striped stalk, which has two or more colours, &c.

STALLION, or STONE-HORSE, in the manege, an ungelt horse, designed for the covering of mares, in order to propagate the species. See the articles HORSE and MARE.

STAMINA, in botany, those fine threads or capillaments growing up within the flowers of tulips, lilies, and most other plants, around the style or pistil. See PLANT.

The word is Latin, and literally signifies threads.

STAMINA, in the natural body, are defined to be those simple original parts, which existed first in the embryo, or even in the seed, and by whose distinction, augmentation, and accretion, by additional juices, the animal body, at its utmost bulk, is supposed to be formed.

STAMINEOUS, in botany, a term used by authors, for those flowers of plants which have no petals, or flower-leaves, but consist only of a number of stamina and pistils placed in a cup. This cup is sometimes mistaken for a flower, and its leaves thought to be true petals, but they remain when the stamina are fallen, and become the capsules containing the seed; which, according to Tournefort, is the true character of a cup, not of a flower.

STAMP-DUTIES, certain impositions laid on all parchment and paper, on which deeds, grants, or other instruments, or any process in law or equity, are ingrossed or written.

The stamp-duties are also extended to almanacs, newspapers, pamphlets, cards, and dice. All pamphlets above a sheet, and under six sheets in octavo, twelve in quarto, or twenty in folio, are subject to a stamp-duty.

STAMPS, in metallurgy, a sort of large pestles, lifted up by water wheels, and serving to beat to powder the ores, and the refuse of ores, of metals. This engine is called

called the stamping-mill, and sometimes the knocking-mill.

STAND, in commerce, a weight, from two hundred and a half to three hundred, of pitch.

STANDARD, in war, a sort of banner or flag borne as a signal for the joining together the several troops belonging to the same body.

Du Cange derives the word from *standarum*, or *stantarum*, *standarum* or *standale*, words used in corrupt Latin, to signify the principal flag of an army. Menage derives it from the German *stander*, or the English *stand*.

The standard is usually a piece of silk, a foot and a half square, on which are embroidered the arms, device, or cypher, of the prince, or of the colonel: it is fixed on a lance eight or nine feet long, and is carried in the center of the first rank of a squadron of horse.

The standard is used for any martial ensign of horse, but more particularly for that of the general, or the royal standard: those borne by the foot are rather called colours.

STANDARD, in commerce, the original of a weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try the weights used by particular persons in traffic.

The justness of weights and measures is of that importance to the security and good order of trade, that there is no civilized nation, but makes it a part of their policy, to preserve the equality thereof, by means of standards. The standards of weights and measures in England are appointed by magna charta to be kept in the exchequer by a special officer, called the clerk or comptroller of the market.

The standard of gold-coin is twenty-two carats of fine gold and two carats of alloy in the pound weight troy: and the French, Spanish, and Flemish gold are nearly of the same fineness. The pound weight is cut into forty-four parts and a half, each current for twenty-one shillings. The standard of silver is eleven ounces and two penny-weights of silver, and eighteen penny-weights of alloy of copper. Whether gold or silver be above or below standard, is found by assaying, and the hydrostatical ballance.

STANDARDS, or STANDELS, in husbandry, are young trees, reserved at the felling of woods, for the growth of timber.

STANNARIES, the mines and works where tin is dug and purified, as in Cornwall, Devonshire, &c. There are four courts of the stannaries in Devonshire, and as many in Cornwall, and great liberties were granted them by several acts of parliament, in the time of Edward I. &c. though somewhat abridged under Edward III. and Charles I.

STANZA, in poetry, a certain stated number of grave verses containing some perfect sense, terminated with a rest or pause.

The word is Italian, and literally signifies a *stand*, or *station*, because of the pause to be made at the end of each stanza, or complete sense.

What the couplet is in songs, and the strophe in odes, the stanza is in the greater and graver pieces; as epic poems, &c.

STAPES, in anatomy, a little bone situated in a cavity of the fenestra ovalis; thus called from its resembling a stirrup.

STAPLE, *Stapula*, primarily signifies a public place or market, whither merchants, &c. are obliged to bring their goods to be bought by the people: as the Greve, or the places along the Seine, for the wines and corns of Paris; whither the merchants of other parts are obliged to bring those commodities.

Vossius and Menage derive the word from *stapulus*, which is found in the ripuary laws, signifying a place where justice is administered.

STAPLE also signifies a city or town where merchants jointly agree to carry certain commodities, as wool, cloth, lead, tin, &c. in order to their being commodiously sold by the great. In England, staples are settled and appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Norwich, Westminster, Canterbury, Chichester, Winchester, Exeter, and Brif-

tol, to which places merchants and traders were to carry goods to sell in those parts.

The staple commodities of England are chiefly wool, leather, cloth, tin, lead, &c. though by staple goods is now meant any proper saleable commodities not easily subject to perish.

STAR, *Stella*, in astronomy, a general name for all the heavenly bodies, which, like so many brilliant studs, are dispersed throughout the whole heavens.

The stars are distinguished, from the phenomena of their motion, &c. into fixed, and erratic or wandering stars: these last are again distinguished into the greater luminaries, viz. the sun and moon; the planets, or wandering stars, properly so called; and the comets.

As to the fixed stars, or simply stars, they are so called because they seem to be fixed, or perfectly at rest, and consequently appear always at the same distance from each other.

Distribution and Number of the Fixed STARS. An observer will first divide these stars into several classes, according to the splendor of their light; the brightest he will call stars of the first magnitude; those of the next inferior light, he will call stars of the second magnitude; and so in order to those which can barely be seen by the naked eye, which are called stars of the sixth magnitude: and those which cannot be seen but by the help of magnifying glasses, are of the seventh, eighth, &c. magnitudes. Afterwards, to avoid confusion, and to be able to point out any one star, without being obliged to give a particular name to each, he will divide them into separate parcels, of which he will make a particular plan; and to each of these constellations, or parcels of stars, he will assign a figure at pleasure, as that of a ram, a bull, a dragon, a Hercules, &c. but so that all the stars in each of the parcels, drawn in the plan, may be enclosed in the designed figures, and correspond to the different parts from whence they take their name: for example, having drawn the figure of a bull about a parcel, or constellation, of stars, that star which falls in the eye, will be called the star in the bull's eye, or simply, the bull's eye; another, which respects the tip of one horn, will be named the bull's horn; and so of others. A parcel of stars thus contained in any assigned figure, is called a constellation.

By this means, notwithstanding the seeming impossibility of numbering the fixed stars, their relative situations one to another have been so carefully observed by astronomers, that they have not only been able to number them, but even to distinguish the place of each star in the heavens, and that with greater accuracy than any geographer could ever point out the situations of the several cities or towns upon the surface of the earth; and not only the places of those few, if they may be so called, which are to be seen with the naked eye, have been pointed out and registered by them, but even of those which are discovered only by the telescope. The most ancient observations of the stars, which have reached these times, were made by Timocharis and Aristillus, about 300 years before Christ. The next after them, who made a catalogue of the stars visible to the naked eye, and registered their places, was Hipparchus of Rhodes; he flourished about 120 years before Christ, and numbered 1022 stars. After him, Ptolemy enlarged his catalogue to 1026: Ulug Beigh, the grand-father of Tamerlane the Great, about the year 1437, constructed a new catalogue, more exact than that of Ptolemy, containing 1017 stars: Tycho, in the year 1600, determined the places of 777 fixed stars, and reduced them to a catalogue: Kepler's catalogue contained 1163 stars; and that of the prince of Hesse, 400: Ricciolus enlarged Kepler's catalogue to 1468; and John Bayer, a German, had described the places of 1725 stars: after this, about 1670, Hevelius of Dantzick, composed a catalogue of 1888 fixed stars: Dr. Halley also undertook a voyage to the island of St. Helena, in order to take the position of the stars within the antarctic circle, of which he published a catalogue, containing 373 stars; but the largest and most complete catalogue ever yet published, is that of our accurate astronomer Mr. Flamsteed, in his *Celestial History*, which contains near 3000 stars; all whose places are more exactly determined in the heavens, than the position of cities and other places on the earth.

We ought not, however, to imagine, that all the fixed stars are thus numbered, and reduced to their respective places in the heavens; since their number continually increases, according to the goodness of the telescope, appearing millions beyond millions, till, by their immense distance, they evade the sight, even though assisted by the best instruments. The telescopic stars with which Mr. Flamsteed has enriched his catalogue, are only the more remarkable ones, whose longitudes and latitudes, or situations in the heavens, it was thought worth while to register and put down. Dr. Hook, with a telescope of twelve feet, saw 78 stars among the Pleiades; and with a longer telescope still more; and, in the single constellation of Orion, which, in Mr. Flamsteed's catalogue, has but 80 stars, there have been seen 2000. We may, therefore, venture to pronounce the number of fixed stars, including the telescopic ones as well as those visible to the naked eye, to be infinitely great, far beyond what it is possible for the best astronomers to calculate, much less to reduce to order. But though the stars are certainly innumerable, yet those visible to the naked eye, in one hemisphere, seldom exceed a thousand; which, perhaps, may appear strange, since, at first sight, their number seems immensely great; but this is only a deception of sight, arising from a confused and transient view; for let a person single out a small portion of the heavens, and after some attention to the situation of the more remarkable stars therein, begin to count, he will soon be surprised to find how few there are therein. However, even the number of stars visible to the naked eye, small as it is in comparison with that of the telescopic ones, is far from being constant; since, besides that the different states of the atmosphere renders many of the lesser stars invisible, some stars have been observed to appear and disappear by turns; particularly one in the chair Cassiopeia, in the year 1572, which, for some time, outshone the biggest of the fixed stars, and in sixteen months time, by degrees, vanished quite away, and was never seen since: in the year 1640, the scholars of Kepler saw a star in the right leg of Serpentarius, which likewise gradually disappeared: Fabricius, in the year 1596, gives the first account of the *stella mira*, or wonderful star, in the neck of the Whale; which has been since found to appear and disappear periodically, its period being seven revolutions in six years, but is never quite extinguished. Several other new stars have been observed: as one by Hevelius, in 1670; and another by Mr. Kirch, in 1689. These new stars are generally observed in the galaxy, or milky way.

As to the causes of this appearing and disappearing of the fixed stars, Sir Isaac Newton conjectures, that as it is possible our sun may sometimes receive an addition of fuel by the falling of a comet into it: so the sudden appearance of some stars, which formerly were not visible to us, may be owing to the falling of a comet upon them, and occasioning an uncommon blaze and splendor for some time: but that such as appear and disappear periodically, and increase by very slow degrees, seldom exceeding the stars of the third magnitude, may be such as having large portions of their surfaces obscured by spots, may, by revolving round their axes, like the sun, expose their lighter and darker parts to us successively.

Nature and Distance of the Fixed Stars. From the similitude there appears to be between them and the sun, it is generally supposed by philosophers, that they are not placed in the heavens by way of ornament only, or to supply us with a faint light in the absence of the moon; but that each of them is placed in the midst of a system of planetary worlds, and that it directs their motions, and supplies them with light and heat, in the same manner that the sun does the several bodies of which our solar system is composed; in short, that they are so many suns, which no doubt have planets moving regularly round them, though invisible to us. That this is not mere hypothesis, will appear from the following arguments, drawn from the analogy they bear to our sun: the sun shines by its own native light, and so do the fixed stars: the sun, at the distance of the fixed stars, would appear no larger than a star; none of our planets, at that distance, could be seen at all: is it not probable,

therefore, that each of the fixed stars is a fixed sun, surrounded by a system of planets and comets, which may be again furnished with different numbers of satellites, or moons, though invisible to us? Besides, as the number of stars is immensely great, dispersed through spaces of the universe, far beyond the reach of the best telescopes, and as God has made nothing in vain, it seems highly probable that they severally serve the purposes of light and heat for the planets of their systems; since nothing can be more absurd than to pretend that myriads of unseen stars were made to twinkle in the unknown regions of the universe.

That the fixed stars shine by their own light is thus proved: when viewed through a telescope, they appear only as mere lucid points, destitute of all sensible magnitude, and consequently must be at a vast distance; because the satellites of Jupiter and Saturn, when viewed through a telescope, appear of very distinguishable magnitudes, and yet are invisible to the naked eye. Since, then, the fixed stars are at such a vast distance, that the best telescope has no power to magnify them, and nevertheless shine with a very bright and sparkling light, it is inferred that they must shine with their own proper and unborrowed light; because, if their light was only borrowed, they would, like the satellites already mentioned, be invisible to the naked eye.

The celebrated Huygens found the brightest and largest, and consequently the nearest of the fixed stars, viz. Sirius, or the dog-star, to be in appearance 27664 times less than the sun; and since the distances of objects are greater as their apparent magnitudes are lesser, the dog-star must be distant from our earth 2000000000000, or above two millions of millions of English miles: which is so very great, that a cannon-ball continuing in the same velocity it acquires when immediately discharged at the mouth of the cannon, would spend almost seven hundred thousand years in passing through it: and it is very probable, that the fixed stars are equally distant from each other, as the nearest of them is from our sun; since, the better the telescopes we make use of, the more stars are seen. Hence it is very natural to conclude, that all the fixed stars are not placed at equal distances from us: but that they are every where interspersed, at great distances beyond one another, throughout the universe; and that, probably, the different appearances which they make, in point of splendor and magnitude, may be rather owing to their various distances from us, than to any real difference in their magnitudes.

From what has been said, concerning the number, nature, and distance of the fixed stars, the hypothesis of a plurality of worlds, wherein each fixed star serves as a sun to a system of planets, seems rational, worthy a philosopher, and greatly displays the wisdom, and redounds to the glory, of the great Creator and Governor of the universe.

Apparent Motions of the Fixed Stars. See ABERRATION.

Falling Stars, Stellæ cadentes, in meteorology, fiery meteors, which dart through the sky in form of a star; being occasioned by a nitro-sulphureous matter, the common cause of all such meteors.

STAR, in heraldry, a charge frequently borne on the shield, and the honourable ordinaries, in figure of a star; which differs only from the mullet, in not being pierced as this last is.

STAR is also a badge of honour, worn by the knights of the garter, bath, and thistle.

STAR, in pyrotechny, a composition of combustible matters, which, being thrown aloft in the air, exhibits the appearance of a real star.

Stars are chiefly used as appendages to rockets, a number of them being usually inclosed in a conical cap or cover, at the head of the rocket, and carried up with it to its utmost altitude, where the stars, taking fire, are spread around, and exhibit an agreeable spectacle.

To make stars, mix three pounds of salt-petre, eleven ounces of sulphur, one of antimony, and three of gunpowder dust: or twelve ounces of sulphur, six of salt-petre, five and a half of gunpowder-dust, four ounces of oilibum, one of mastic, camphire, sublimate of mer-

E c c

cury,

cury, and half a one of antimony and orpiment. Moisten the mass with gum water, and make it into little balls of the size of a chesnut, which dry either in the sun or the oven. These, set on fire in the air, will represent stars.

STAR-CHAMBER, a chamber at Westminster, so called from having its roof painted with gilt stars.

STAR-FISH, *Asterias*, or *Stella marina*, in zoology, a genus of naked insects, in the form of a radiated star: the mouth is situated in the centre, on the under part; and the anus in the center, on the upper part; the tentacula are extremely numerous, and in a manner cover, either the whole upper surface of the body, or the extremities of the ramifications.

The species of this genus, being very numerous, are distinguished according to the number of their rays; they are also of different sizes; the largest, or great Magellanic star-fish, forming a circle of three feet in diameter, when its rays are fully extended, others not exceeding an inch in diameter.

STAR-SHOT, a gelatinous substance frequently found in fields, and supposed by the vulgar to have been produced from the meteor called a falling-star: but, in reality, is the half digested food of herons, sea-mews, and the like birds; for these birds, when shot, have been found, when dying, to disgorge a substance of the same kind.

STAR-STONE, *Asteria*, in natural history, a name given to certain extraneous fossil stones, in form of short, and commonly somewhat crooked, columns, composed of several joints; each resembling the figure of a radiated star, with a greater or smaller number of rays in the different species: they are usually found of about an inch in length, and of the thickness of a goose-quill. Some of them have five angles, or rays, and others only four; and in some the angles are equidistant, while in others they are irregularly so; in some also they are short and blunt, while in others they are long, narrow, and pointed; and some have their angles so very short and obtuse, that at first sight they might be taken for entrochoasteria. The several joints in the same specimen are usually all of the same thickness; this however is not always the case, but in some they are larger at one end, and in others at the middle, than in any other part of the body; and some species have one of the rays bifid, so as to emulate the appearance of a fix-rayed kind.

STARCH, a fecula or sediment, found at the bottom of vessels wherein wheat has been steeped in water; of which fecula, after the bran is separated from it, by passing through sieves, they form a kind of loaves, which being dried in the sun, or an oven, is afterwards broke in little pieces, and so sold.

The best is white, soft, and friable, easily broke into powder. Such as require very fine starch, do not content themselves, like the starchmen, with refuse wheat, but use the finest grain. The process of making starch of wheat is as follows: The grain, being well cleaned, is put to ferment in vessels full of water, which they expose to the sun when in its greatest heat, changing the water twice a day, for the space of eight or twelve days, according to the season. When the grain bursts easily under the finger, they judge it sufficiently fermented. The fermentation perfected, and the grain thus softened, it is put handful by handful into a canvas bag, to separate the flour from the husks, which is done by rubbing and beating it on a plank, laid across the mouth of the empty vessel that is to receive the flour.

As the vessels are filled with this liquid flour, there is seen swimming at the top a reddish water, which is to be carefully skimmed off from time to time, and clean water put in its place; which, after stirring the whole together, is all to be strained through a cloth or sieve, and what is left behind put into the vessel with new water, and exposed to the sun for some time; and, as the sediment thickens at the bottom, they drain off the water four or five times, by inclining the vessel, but without passing it through the sieve; what remains at bottom, is the starch, which they cut in pieces to get out, and leave it to dry in the sun; when dry, it is laid up for use.

STATE, the policy or form of government of a nation.—Hence ministers of state, reasons of state, &c.

STATES, or ESTATES, a term applied to several orders or classes of people assembled to consult of matters for the public good.

Thus states-general, is the name of an assembly consisting of the deputies of the Seven United Provinces.

States of Holland are an assembly consisting of the deputies of the council, or colleges of each city, wherein resides the sovereignty of that province.

STATICS, that branch of mathematics which considers the motion of bodies arising from gravity. See MOTION.

Statics then is the doctrine, or theory, of motion, considered merely as arising from the weight of bodies; in which sense it is distinguished from mechanics, which is the application of statics to machines, engines, &c. though it must be owned, that statics and mechanics are frequently confounded.

STATICS, in medicine, a kind of epileptics, or persons seized with an epileptic fit; during which they contemplate some strong and lively idea, whereby they are distinguished from cataleptics, or persons seized with a catalepsy.

STATION, in geometry, surveying, &c. a place pitched upon to make an observation, take an angle, or the like.

STATIONARY, in astronomy, signifies the appearance of a planet, when it seems to remain immoveable on the same point of the zodiac for several days.

As the earth, whence we view the motions of the planets, is out of the center of their orbits, the planets appear to proceed irregularly; being sometimes seen to go forwards, that is, from west to east, which is called the direction; sometimes to go backwards, or from east to west, which is called the retrogradation. Now between these two states there must be an intermediate one, wherein the planet neither appears to go backwards nor forwards, but to stand still, and keep the same place in her orbit; which is called her station; and this will happen, when the line that joins the earth's and planet's center is constantly directed to the same point in the heavens; that is, when it keeps parallel to itself. For all right lines, drawn from any part of the earth's orbit, parallel to one another, do all point to the same star; the distance of these lines being insensible, in comparison of that of the fixed stars.

Saturn is seen stationary at the distance of somewhat more than a quadrant from the sun; Jupiter at the distance of fifty-two degrees; and Mars at a much greater distance.

Saturn is stationary eight days, Jupiter four, Mars two, Venus one and a half, and Mercury an half, though the several stations are not always equal.

STATIONARY-DAYS, in church-history, an appellation given to the weekly fast-days, viz. Wednesdays and Fridays; otherwise called half-fasts, and fasts of the fourth and sixth days of the week.

These fasts are certainly as ancient as Clemens Alexandrinus and Tertullian, who both mention them; and the reason of their institution is, because on the fourth day of the week the Jews took council to put our Saviour to death, which was actually accomplished on the sixth: however, being in continual use throughout the year, they were not kept with such rigour and strictness as Lent.

STATIONARY-FEVER, a peculiar kind of fever, adapted, and owing, to some general constitution of the air and seasons. Sydenham observes, that there are certain general constitutions of years which owe their origin neither to heat, cold, dryness, nor moisture, but rather depend upon a certain secret and inexplicable alteration in the bowels of the earth, whence the air becomes impregnated with such kinds of effluvia as subject the human body to peculiar distempers, so long as that kind of constitution prevails, which after a certain course of years declines, and gives way to another. Each of these general constitutions is attended with its own proper and peculiar kind of fever, which never appears in any other; and this is thence called a stationary-fever.

STATIVA, among the Romans, a standing-camp kept for the defence of the frontiers of the empire. These camps gave rise to a great many towns, which took their names from the legion stationed there.

STA-

STATUARY, *Statuaria*, a branch of sculpture, employed in the making of statues.

Statuary is one of those arts wherein the ancients surpassed the moderns; and indeed it was much more popular, and more cultivated among the former than the latter. It is disputed between statuary and painting, which of the two is the most difficult and the most artful. Statuary is also used for the artificer who makes statues. Phidias was the greatest statuary among the ancients, and Michael Angelo among the moderns.

STATUE, *Statua*, is defined to be a piece of sculpture in full relievo, representing a human figure. Daviler more scientifically defines statue a representation, in high relievo and insulate, of some person distinguished by his birth, merit, or great actions, placed as an ornament in a fine building, or exposed in a public place, to preserve the memory of his worth. In strictness, the term statue is only applied to figures on foot, the word being formed from *statura*, the size of the body.

Statues are formed with the chissel of several matters, as stone, marble, plaster, &c. They are also cast of various kinds of metal, particularly gold, silver, brass, and lead. For the method of casting statues, see the article CASTING.

Statues are usually distinguished into four general kinds: the first are those less than the life, of which kind we have several statues of great men, of kings, and of gods themselves; the second are those equal to the life, in which manner it was that the ancients, at the public expence, used to make statues of persons eminent for virtue, learning, or the services they had done: the third, those that exceed the life, among which, those which surpassed the life once and a half, were for kings and emperors, and those double the life, for heroes: the fourth kind were those that exceeded the life twice, thrice, and even more, and were called colossuses.

Every statue resembling the person it is intended to represent, is called *statua iconica*. Statues acquire various other denominations. 1. Thus allegorical statue, is that which, under a human figure, or other symbol, represents something of another kind, as a part of the earth, a season, age, element, temperament, hour, &c. 2. Curule statues, are those which are represented in chariots drawn by bigæ, or quadrigæ, that is, by two, or four horses; of which kind there were several in the circuses, hippodromes, &c. or in cars, as we see some, with triumphal arches, on antique medals. 3. Equestrian statue, that which represents some illustrious person on horse-back, as that famous one of Marcus Aurelius, at Rome: that of king Charles the first, at Charing-Cross; King George the second, in Leicester-Square, &c. 4. Greek statue denotes a figure that is naked and antique; it being in this manner the Greeks represented their deities, athletæ of the Olympic games, and heroes: the statues of heroes were particularly called Achillean statues, by reason of the great number of figures of that prince in most of the cities of Greece. 5. Hydraulic statue, is any figure placed as an ornament of a fountain or grotto, or that does the office of a jet d'eau, a cock, spout, or the like, by any of its parts, or by any attribute it holds; the like is to be understood of any animal serving for the same use. 6. Pedestrian statue, a statue standing on foot; as that of King Charles the second, in the Royal-Exchange; and of King James the second, in the Privy-Gardens. 7. Roman statue, is an appellation given to such as are clothed, and which receive various names from their various dresses.

Those of emperors, with long gowns over their armour, were called *statuæ paludatæ*; those of captains and cavaliers, with coats of arms, *thoracatæ*; those of soldiers, with cuirasses, *loricatæ*; those of senators and augurs, *trabeatæ*; those of magistrates, with long robes, *togatæ*; those of the people, with a plain tunic, *tunicatæ*; and, lastly, those of women, with long trains, *stolatæ*.

The Romans had another division of statues into divine, which were those consecrated to the gods, as Jupiter, Mars, Apollo, &c. Heroes, which were those of the demi-gods, as Hercules, &c. and Augusti, which were those of the emperors, as those two of Cæsar and Augustus, under the portico of the Capitol. In repairing a statue cast in a mould, they touch it up with a chissel, graver,

or other instrument, to finish the places which have not come well off: they also clear off the barb, and what is redundant in the joints and projectures.

STATURE, the size or height of a man.—From the Latin *statura*, or *stare*, to stand.

The stature, or pitch of a man, is found admirably well adapted to the circumstances of his existence. Had man, observes Dr. Grew, been a dwarf, he could scarce have been a reasonable creature: for, to that end, he must have had a jolt head; and then he would not have had body and blood to supply his brain with spirits: or, if a small proportional head, there would not have been brain enough for his business.—Again, had man been a giant, he could not have been so commodiously supplied with food; for there would not have been flesh enough of the best eatable beasts to supply his turn; or, if the beasts had been made proportionably bigger, there would not have been grass enough, &c.

It is a common opinion, however, and has been so ever since Homer's time, that people, in the earliest ages of the world, much surpassed the moderns in stature; and it is true, we read of men, both in sacred and profane history, whose pitch appears surprising: but then it is true, that they were esteemed giants.

The ordinary stature of men, Mr. Derham observes, is, in all probability, the same now, as at the beginning; as may be gathered from the monuments, mummies, &c. still remaining. The oldest monument in the world is that of Cheops in the first pyramid of Egypt, which, Mr. Greaves observes, scarce exceeds the measure of our ordinary coffins. The cavity, he says, is only 6.488 feet long, 2.218 feet wide, and 2.160 deep: from which dimensions, and those of several embalmed bodies, taken by him in Egypt, that accurate writer concludes, there is no decay in nature; but that the men of this age are of the same stature as those three thousand years ago.

To these we have other and later instances to add from Hakewell: the tombs at Pisa, which are some thousands of years old, are no longer than ours. The same may be said of Athelstan's in Malmsbury church; Sheba's in Paul's, of the year 693, &c.

The like evidence we have from the ancient armour, shields, vessels, &c. dug up at this day; for instance, the brass helmet dug up at Metaurum, fits one of our men; yet it is allowed to have been left there at the overthrow of Asdrubal. Add, that Augustus was five feet nine inches, which was the measure of our queen Elizabeth; only the queen exceeded the emperor by two inches, allowance being made for the difference between the Roman and our foot.

STAVERS, or STAGGERS, among the farriers, a giddiness in a horse's head, which ends in madness. The signs of it are dimness of sight, reeling and staggering, watery eyes, &c. at length, for very pain he beats his head against the wall, thrusts it into the litter, rises and lies down with fury, &c. The methods of cure are various; but they all begin with bleeding. However, the most approved remedy for this distemper, which shews itself in horses in a giddiness, and reeling about, in wateriness of the eyes, and a variety of odd motions of the head, is the following method: The creature is first to be blooded largely, then a glyster is to be given him, composed of two quarts of emetic wine, and four ounces of the unguentum populneum. When he has reposed an hour or two after voiding his glyster, let another be given him, made of two ounces of the scorix of the liver of antimony finely powdered, boiled a little while in five pints of beer, and with the addition of four ounces of the same ointment, or of ointment of roses. This last glyster is to be frequently repeated, and his legs are to be all the while rubbed strongly with wisps of hay, wetted in warm water, to make a revulsion. His food should be bran and white-bread, and he should be walked from time to time in some temperate place. If these methods do not succeed, let an ounce of Venice treacle be dissolved in a quart of some cordial waters, and given him; and, after this, let the following glyster be given warm: Take Venice treacle and sal polychrestum, of each two ounces; dissolve them in two quarts of a decoction of mallows and camomile flowers; add a quarter of a pint of oil of rue. This repeated

repeated two or three times after bleeding, and the other methods, will often cure the worst stages of this disease.

STEEL, a kind of iron refined and purified by the fire with other ingredients, which renders it whiter, and its grain closer and finer than common iron.

Steel, of all other metals, is that susceptible of the greatest degree of hardness, when well tempered; whence its great use in the making of tools and instruments of all kinds.

The manner of making iron into steel had remained very long a secret; but many authors of late date have given the process, though it does not appear the same in all, and in many is encumbered with circumstances intended only to disguise it. Mr. Reaumur has taken greater pains, than almost any man, to come at the truth; but, to be rightly informed of his reasons, we ought to begin where he did, that is, at the origin of the iron in its pure metallic state.

The ores of this metal are mixed bodies, composed of some particles truly metallic, and of others sulphureous, saline, and terrene; this compound mass is put in fusion by the fire, and on this operation the metallic parts, being heaviest, subside to the bottom of the vessel, or furnace, and are then easily separated from the lighter substances which float at the top. This separation, however, is not supposed to be perfect; but the metal, after this its first fusion, retains many heterogeneous particles, which prevent it from being malleable. It is after this to be refined, that is, to be melted again, and, that ever so often performed, the metal becomes yet more and more pure and perfect, some heterogeneous matter being every time deposited, or thrown off; and this is usually much less after every fusion. The metal, when thus purified, by melting, yet remains hard and brittle: these are two qualities which we do not want in iron, and this hardness and friability are no incompatible qualities, since their origin is this, that the iron in this state is composed of a multitude of small granules, every one of which is very firm and compact in its own texture, though they cohere but slightly one with another. The knife, or the file, cannot easily cut any one of these granules, but a blow of a hammer easily separates large parcels of them from those to which they were joined: this cast iron is therefore used only for such purposes as requires a substance possessed of these qualities; purposes where hardness is required, and where no blows are to be met with. Thus, backs of grates, iron pots, and the like, are made of it.

One of the general properties of metals is, that they are malleable; that is, their several particles cohere so well together, that they are ductile and extensible under the hammer, and will suffer the whole mass to bend any way without breaking, that is, without their separating from one another. In the works of the artificers, such suppleness and pliability is called *body* in a metal, and the cast iron, which wants this, is said to have no body, and is what they call *no soft metal*. It is therefore no way fit for such works as require fashioning by the hammer or the file, nor of such as are to stand any violent blows; but, as it is easily fusible, it serves for the cast works where there is no great delicacy in the figuring, since it does not run so thin as to adapt itself to every lineament of a fine figure, nor is qualified to be repaired by instruments.

The ill qualities of cast iron are, in a great degree, remedied in the forged or wrought iron, taken from the same quantity, and the same fusion. The forging of iron is only the placing it over the fire till heated to a certain degree, and then beating it out with large hammers till it becomes soft. When it has been sufficiently forged, it becomes soft and malleable, even when cold, and, when heated, is easily wrought into any figures, which it retains afterwards; and it is easily cut by the file when cold, and is not brittle on being struck, as is the cast iron.

While it gains these properties by the forging, it loses, however, another by the same means, which is its fusibility. It will no longer melt in the fire, but when the workmen give it the strongest heat they can, it is only reduced to a sort of soft paste, and sweats a little, as

they express it; that is, some few drops of truly melted iron fall from it.

It is very certain, that both the cast and the forged iron are mixtures of metalline, saline, and sulphureous particles; and the different arrangement of these, in their mere simple running together in the fusion, and their being driven intimately into, and among one another, by the hammering, makes the fusibility different in the two states.

If the forged iron differ greatly from the cast, there is however a third state into which it is reducible by art, which is yet different from both; this is what we call *Steel*; and the quality of iron on receiving this change is not one of its least valuable ones, since from this we have all our instruments for cutting, sawing, boring, and the like purposes, the value of which to us is almost infinite. The German steel has always been in great repute, and, though several other nations have made it, yet the Germans have kept their method a sacred mystery, to keep up their trade in it.

Steel is considerably harder than forged iron, and so it is necessary that it should be, in order to many of the purposes it is employed in. Shears of steel, which are intended to cut iron, must be harder than iron, otherwise their edge will turn, and they will not cut; whereas, if the metal is too hard, then the granules will fly off, and the edge break away in small fragments. This is the case with all edged tools; and hence it is, that good steel is so nice and difficult a thing to make, since there is required such a degree of hardness, and no more.

It is very well known, that steel acquires its hardness from the plunging it into water; it is to be heated to a certain degree, and then immediately plunged, while the fiery particles yet remain in it, into water perfectly cold; it is then to be speedily drawn out of the water, and thus the whole operation is finished. It acquires its hardness in degrees, proportionate to its heat when plunged into the water; and this hardness, or temper, remains with it only till it is heated as high again; for, after that, if left to cool leisurely, and not thrown into water, it is lost. All the masses of steel which are sold are thus tempered; nevertheless, when they are wrought into tools, their temper is lost, and is to be renewed by plunging them again into cold water, when they have been forged into the shape of which they are to be.

Mr. Reaumur affirms, that steel differs in nothing from forged iron, except that it contains more sulphurs, and more salts. Hence, it follows, that cast iron should be steel, since it evidently differs from forged iron in the same manner, and by the same properties; and, in effect, cast iron is steel, such as it is, especially the white sort, which is more pure, and more perfectly divested of its earth, than the browner sorts; and this white kind may be accordingly brought to all the hardness of steel, by repeated heating and quenching in cold water. It follows also, that in order to convert iron into steel, we are to give it new salts and new sulphurs. It may be asked, where is the necessity of giving again that which the mere cast iron possesses? To which the answer is, that steel is required to be malleable in some degree, which the mere cast iron is not; and it is to be added to this, that it may be possible for us to give to forged iron such salts and sulphurs as are more proper for the steel, than those which the cast iron naturally possesses.

We have great variety of salts and sulphurs, out of which to chuse for this purpose, and Mr. Reaumur made many trials to find which would succeed best; and the result of all was, that, for sulphurs, powdered charcoal and common foot; and, for salts, sea salt alone succeeded best; and that these were properly to be mixed with ashes, by way of an intermediate substance.

These substances must also have their allotted dose; that is, there must not only be a certain proportion of the several ingredients one to another, which, however, need not be very precise and exact, but there must also be a proportional quantity of the whole employed to the quantity of iron that is to be wrought upon; and in this also regard must be had to the several sorts of ores from which the iron was obtained, since the iron of some
ores

ores is much sooner convertible into steel than that of others, and makes also a better steel.

The manner of best introducing these salts and sulphurs into the body of the iron was found by this author a matter of great difficulty to determine. He soon perceived, that fire was the only agent that could convey these bodies into the metal; and in contriving how this might be done most easily, and with least expence, he found out, after many trials, a new sort of furnace, which effected this purpose with great ease, and which was not subject to the inconveniencies of other furnaces.

As steel is iron with an admixture of heterogeneous particles, it follows that it must be less metallic, that is, less malleable, or more brittle; it is also necessary that it must be, in some degree, malleable for the purpose it is required for; and it is easy to conceive that these properties cannot be given it, in a proper degree, but by means of a very accurate operation; and, even when all the parts of the process are the same, there is yet much depending on the iron itself, which can never be perfectly known but by trial. Something, however, may be judged of the iron by breaking bars of it: the several sorts of iron, when broken, shew some of them only granules, others flakes, and others fibres; some also shew all three of these molecularæ at once, and others two of them; but it is easy, in either of these cases, to see which sort is in the greatest number.

The laminated and the fibrous iron are the two extremes; the first is very brittle, the latter very malleable. The laminated iron is ever the worst of all kinds for making into steel; and of this kind such pieces are worst of all, the laminæ of which are very white and shining, and are large and irregularly disposed, and arranged in different inclinations. Mr. Reaumur began to reckon from these an arrangement of all the kinds of iron, which coming, each by degrees, to have the laminæ still smaller and smaller, and at the same time less glittering, and placed more evenly together, sunk at last into the irons of the granulated kind. It is easy to conceive how many differences there must be between these; and from these the fibrous ones may be deduced, owing their texture merely to the granularæ, which in these are disposed into long strings or streaks. Though, in this arrangement of the irons, the first are, of all others, the least proper for making steel, it does not follow that the last are the most so; these indeed usually make a very soft and pliant sort of steel, which has what the workmen call the greatest body of all the kinds of steel, and is therefore most proper of all for certain purposes, as the making of watch springs, and the like; but the want of hardness makes it very unfit for cutting tools of all kinds, from the razor to the ax. The granulated iron always makes the finest and hardest steel: and of these such succeed best, whose granules are smallest.

One thing remarkable is, that all steel, though made of iron of the granulated or striated kind, yet is, before it has been hammered, of a flaky, or a sort of laminated structure; but this seems owing to the fire's having melted some of the granules in the operation, and run great numbers of them together into these plates. The smallness of these flakes in steel, which has not been worked, are a proof of its being a bad kind.

A bar of iron, when converted into steel, is not equally so converted in all its parts; the fire has always acted more strongly on its surface than on its central parts, and it is therefore more perfectly steel there than in its inner parts; but a perfection in the operation is not necessary to the steel's being good and useful, and the whole bar is often very good steel, as are also many bars made at the same time, yet all, perhaps, somewhat differently affected.

If the composition, which is to convert the iron into steel, be too strong, or if the fire be too violent, or the matter contained too long in it, in all these cases the steel will be over made; that is, there will be an over proportion of saline and sulphureous parts added to the iron: these will therefore too far separate the particles of the metal asunder, and the consequence will be, that the steel will be too brittle to bear hammering, and will be of great loss to the proprietor in the great quantities

that will be broken, besides the loss he will have from the abundance of scales which will fly off in the working. The way to meliorate such steel as this must be to divest it of a part of its salts and sulphurs, but particularly of the last; and Mr. Reaumur found, that by the burying the bars of such steel in lime, or any other alkaline substance that would readily absorb the sulphurs, and placing it for a proper time in the fire, it would be in a manner decomposed again, and come out a very good and perfect steel; and this is no trivial proof, that the account given of the manner of iron's becoming steel is the true one.

By this management steel may again be converted, or reduced to its primitive iron, and a body of any middle degree, between steel and iron, may be produced, by stopping this process at different points of time, or continuing it till all the adventitious salts and sulphurs are drawn off or absorbed. Hardness and flexibility are the two great points of this operation, and what the metal gets of the one of these, it assuredly loses of the other. The greater hardness is from the greater quantity of the adventitious salts and sulphurs; and the greater flexibility, or as the workmen call it, the greater body, is from the greater quantity of the metallic; and he who is able to calculate properly the quantities of his salt, charcoal, and foot, and to regulate exactly the degree of fire, is capable to make steel of what degree of temper or perfection he pleases.

Iron, impregnated with new salts and new sulphurs, is not however perfectly reduced to the state of what the workmen expect in steel; there wants yet the quenching it while hot in cold water, to complete the operation. The steel, penetrated every way by the particles of fire, and at that instant plunged into water, is by that quenching stopped in the very state in which it was, and is not suffered to exhale the igneous bodies, as it would otherwise have done. It was, while in the fire, rarified and dilated, and this quenching continues it in that state, and it is found, on measuring, considerably thicker and larger than it was while unheated. It might be supposed from hence, that the particles of fire, which were lodged in the steel while red-hot, were thus detained and imprisoned in it, and so wrought the change, as they are known to remain in many calcined bodies, though they have not been so suddenly quenched; but, if this were the case, the steel must be increased in weight as well as bigness, as many calcined bodies are; but this is not found to be so in fact.

Recourse must be had therefore to some other operation on the steel; and this appears, in reality, to be no other than the change of its texture, or internal structure. If a body be naturally composed of a number of particles, which are in themselves hard and compact, but between which there are certain spaces; if one takes from these hard and compact particles somewhat to fill up these voids, it must appear very evidently, that, though by this the proper particles are rendered less hard, yet the whole body must be made harder than it was before. In the converting of iron into steel, Mr. Reaumur conceives that the particles of iron, being naturally very covetous of salts and sulphurs, have imbibed great quantities of these adventitious bodies, while the spaces between them have been able to retain very few. This being then the first state of the steel, when it is afterwards heated, in order to its being tempered by quenching, the fire drives these sulphureous and saline particles, so abundant in the iron, out of its granules, and disperses them throughout the spaces between these granules; and that it is to this equal and regular distribution of these salts and sulphurs, fixed in this state by the immediate quenching, that the hardness and other qualities of steel are owing.

To the advantage the metal gets by this means, there is however always joined a disadvantage, which is, that its grain naturally and necessarily becomes coarser by it, and the steel has the less body. The hardest steel always must necessarily have the least body; but according to the rules laid down by Mr. Reaumur, one may dispose the hardness in what degree one pleases, and consequently all the other properties are in the direction of the same laws.

If the opposition of the qualities of steel be nicely considered, we shall find, that, instead of being hurtful, they are truly what should be most wished for, and are productive of the most desirable consequences. It may appear somewhat strange, that hardness and flexibility in steel should be such directly opposite and contradictory principles, and that the quenching, which makes steel more powerful to resist pressure or rubbing, should, at the same time, make it more feeble in action; but this is plainly the case, and a piece of steel wire, which, before it is tempered by quenching, will when hung vertically, suspend a certain weight, will not sustain the same weight when tempered, but will be broken even by a less; and that if the trial be made by tempering it up to one certain part, and no farther, the wire will assuredly break at that very part where the tempered and non-tempered portions meet. The increase of size in every grain of steel, from the quenching, gives the plain solution of this phenomenon. The rupture of any body whatever, that is, the separation of its parts, by whatever means it is done, must be more difficult, the more intimately those parts touch, or the more points they touch in. The granules of steel are those touching parts, and it is very evident that these granules, becoming larger on the quenching, must after this touch in fewer points, in the whole combination of the mass; and, on the other hand, as they are larger, they also must mutually touch each other in a larger space. Here are two contrary principles, which constitute the facility and the difficulty of the rupture by different means; and it cannot be, but that the one of these constrictions must give the greater force to resist pressure or friction, and the other to resist drawing or traction.

It has been already observed that steel is the harder, according as it was more or less hot at the time when it was plunged into the water; and it must be added to this, that it also is the more so, the more cold the water is into which it is plunged. The degree of heat in the steel is easily known by its colour, and the distinctions in it are familiar to the workmen. Several persons have thought there was great virtue to be communicated to the water by means of different ingredients: this Mr. Reaumur carefully tried, and the result was, that he found common cold water the best and most useful of all liquors: it is true, that vinegar and verjuice harden the steel somewhat more, and aqua fortis greatly so; but the latter of these renders it too hard for service, and repeated trials have evinced, that common water alone will give steel all the hardness it can be wished to have, provided only that it be plunged into it at a time when it is sufficiently hot. If steel, after tempering, be found too hard, there is a very familiar way of bringing it back to what state one pleases, between that and iron, which is only the heating it in the fire; for it may be kept in the fire so long, as to be reduced wholly to iron again. It is easy to infer from hence, what was before observed, that cast iron is steel of a peculiar kind; its properties plainly evince, that it is steel with an over proportion of all that makes it so, and consequently of all its properties. It is not malleable, is very brittle, and too hard for the file, or any other tool, to cut. These are the qualities of steel which is over tempered, or, as it may be called, too much steel: it owes these qualities to its being overcharged with those sulphurs and salts, which in a due proportion make steel of iron. The method of reducing this to the state of wrought iron is the same that we have before observed is to be used to untemper too high tempered steel, that is, keeping it in the fire till part of its salts and sulphurs are driven off; and, if the fire alone be thought too difficult or too tedious a method, Mr. Reaumur has found that those alkaline substances, which naturally absorb sulphurs, will assist the reducing this to the state of wrought iron, as they do to the untempering of steel; and that the very same substances of this kind, which have been found best in the untempering steel, succeed best in the rendering this malleable; such are lime, chalk, and the like.

Cast iron may be taken for these operations in two states; the one that of simply melted iron in its first fusion, the other that of the iron which has been run into the mould. When a cast piece of iron, in a

certain form, is heated again with the calx of animal bones, which is one common way, this being a substance extremely divested of salts and sulphurs, it absorbs those of the metal too greedily, and divests it of too great a quantity of them; so that, when the piece comes afterwards to be filed, the fragments fly off in large scales, and the beauty of the cast figure must be lost: to remedy this difficulty, some powdered sulphur is to be added in the heating; for this, being a sulphureous and saline body, checks and moderates the effect of the calx of bone.

Chalk in the same manner can only be employed with certain regulations; it succeeds very well, if the fire be not too violent, or too long continued; but, if it be excessive in either of these particulars, the chalk throws into the body of the iron salts and sulphurs of its own, which lay hid in its structure, and which would not have been dislodged by a smaller fire; but which being dislodged, and thrown into the iron, act upon it, and render the success of the operation quite different from what was intended, the iron becoming more hard and more brittle by it.

One great nicety, in all these operations, is the understanding the signs by which it is known at what time cast iron is sufficiently softened, or overtempered steel is sufficiently reduced towards the state of iron again; but this is only to be acquired by nice observation, and on this depends the whole certainty of the processes, since every minute's continuance in the fire gives the operation a different turn in degree.

Mr. Reaumur, in one of his experiments in the softening a piece of cast iron of a beautiful figure, found, on taking it out, that it had lost prodigiously of its weight; and, coming to a nicer examination, he found that it was hollow, its outer crust having been sooner converted into malleable, that is, into fusible iron, than the rest, and the violence of the fire afterwards having melted away the inner part, which was not yet so changed. This accident led him to experiments, by which he found that he could, at any time, melt out the central part of a thick square bar of cast iron, the outer part changing first into the condition of malleable iron, and serving as a crucible for the fusion of the yet unaltered fusible iron within. By a proper management of this discovery, it will be easy to take off the unwieldy weight of many works of cast iron, which do not require so much strength as that of the solid contained in their circumference. *Mem. de l'Acad. des Scien. 1722.*

Mr. Cramer observes, that the method of making steel out of iron, is either by fusion, or by cementation. That by cementation may be performed in the following manner: chuse some bars of pure iron, not too thick: prepare a cement of charcoal dust, moderately pulverised, one part, and wood ashes half a part; or of charcoal dust two parts, bones, horns, leather, or hair of animals, burnt to a blackness in a close vessel, and in a gentle fire, and afterwards reduced to a powder, one part, wood ashes half a part; mix them together. Prepare a cylindrical earthen vessel, two or three inches higher than the bars are long; put into the bottom of this vessel the cement, prepared as before directed, so that, being gently pressed down, it may cover the bottom of the vessel an inch and a half deep; place then the iron bars perpendicularly, so that they may be every-where an inch distant from the sides of the vessels, and from each other; fill the interstices with the cement, and cover the bars with it, that the vessel may be quite full; cover it with a tile, and stop the joints with a lute; put this vessel into a furnace, and keep it moderately, but equally red-hot, for six or ten hours. When this is over, take the red-hot bars out, and dip them in cold water; they will then be brittle, and turned to steel.

The method of making steel by fusion is this: take of iron ore, or of unmalleable iron of the first fusion; divide it into small parcels, and put them into a bed made of charcoal dust in a smith's forge; let the quantity of the iron be but small for the experiment; put to it, as a defensive menstruum, some of the vitrescent scoriæ of sand, or stones of the same nature; then put upon them a quantity of charcoal; light this, and admit only a small blast of the bellows, that the scoriæ and metal may both melt

melt regularly: when this has been some time kept in fusion, take it out, divide it into two parts, which make red-hot, and hammer into long bars; finally, heat them red-hot, and plunge them into cold water, and they will then be found to be steel, so very hard, as not to be filable; and so brittle, as to break asunder, when struck with a considerable force. *Cramer's Art of Assaying.*

Mr. Lemery shews a simple method of reducing steel to a very fine powder, without rusting it: pour water on filings of steel in an earthen vessel, till it is four inches above the filings; stir it well every day, supplying more water, as that in the vessel subsides, so that the steel is always covered; continue this operation till the steel falls into an impalpable black powder; then dry it for use. *Mem. d'Acad. des Scien. 1736.*

Mr. Boyle tells us of his having opened the body of steel, by a highly rectified spirit of urine made per se, and poured upon new filings of the steel. This being put into a warm place, the menstruum dissolved a considerable part of the metal. *Mem. de l'Acad. des Sciences, 1736.*

Annealing of STEEL, is by some used for the softening it, in order to make it work easier; which is usually done by giving it a blood-red heat in the fire, and then taking it out, and letting it cool of itself.

Steel may indeed be made a little softer than in the common way, by covering it with a coarse powder of cow-horn, or hoofs; thus inclosing it in a loam, heating the whole in a wood fire till it be red-hot, and then leaving the fire to go out of itself, and then the steel to cool. *Mox. Mechan. Exercises.*

STEELING, in cutlery, the laying on a piece of steel upon a larger mass of iron, to make that part which is to receive the edge harder than the rest. The body of an axe may very well be of iron, as it never comes in use to cut with, and perhaps is stronger, and less liable to break than if of steel: but it must have a quantity of steel at that part where the edge is to be made.

STEEL-GLASSES, a name given by some authors to the metalline spheres used in optics. These, according to Cardan, are made of three parts of brass, one part of tin, and one of silver, with an eighteenth part of antimony; but most either totally leave out the silver, or add only a twenty-fourth part, to save the expence. There are many other methods directed by several authors, but most use arsenic and tartar mixed with the metals. These are afterwards to be polished with emery, rotten-stone, putty, and the like.

STEELYARD, *Statera Romana*, in mechanics, a kind of ballance by means of which the gravity of different bodies is found by the use of one single weight. See *BALLANCE*.

STEEPLE, an appendage erected generally on the western end of a church, to hold the bells. Steeples are denominated from their form, either spires or towers; the first are such as ascend continually diminishing either conically or pyramidally. The latter are more parallelopeds, and are covered at the top platform-like.

In each kind there is usually a sort of windows or apertures to let out the sound, and so contrived at the same time, as to drive it down.

STEGANOGRAPHY, the art of secret writing, or of writing in cyphers, known only to the persons corresponding.

STEGNOTICS, in medicine, remedies proper to close and stop the orifices of the vessels, or emunctories, when relaxed, stretched, lacerated, &c.

The word is formed from the Greek, *στέχω*, to hinder, or close.

STELLATE, among botanists, expresses leaves which grow not less than six at a joint, and are arranged like the rays of a star.

STEM, in botany, that part of a plant arising out of the root, and which sustains the leaves, flowers, fruits, &c.

STEMPLES, in mining, cross bars of wood in the shafts which are sunk to mines. In many places the way is to sink a perpendicular hole or shaft, the sides of which they strengthen from top to bottom with wood-work, to prevent the earth from falling in; the transverse pieces of wood used for this purpose, they call

stemples, and by means of these the miners, in some places, descend without using any rope, catching hold of these with their hands and feet.

STENONIAN DUCT, or *Ductus salivus Stenonius*, in anatomy, a name given from Steno, its discoverer, to one of the superior salival ducts, running from each of the parotids, about three fingers long; and of the thickness of a wheat straw; having a great number of roots. This duct passes over the masseter muscle through the middle of the cheek, and there perforates the buccinator muscle, and the membrane of the mouth near the second or third molares, and at this perforation it discharges a very large quantity of its proper fluid into the mouth.

STENTOROPHONIC TUBE, a speaking trumpet, thus called from Stentor, a person mentioned by Homer. See *TRUMPET*.

STEP and Leap, in the manege, one of the seven airs or artificial motions of a horse, consisting, as it were, of three airs, viz. the pace or step, which is terra a terra; the raising, which is the curvet, and the whole finished with a fault or leap. The step properly puts a horse on the hand, and gives him a rise to leap; like one that runs before he leaps, that he may go the higher or the farther. For leaps of all kinds, the rider is not to give any aids or helps with his legs, only to hold the horse well up with the bridle-hand when he rises before, that he may rise the higher behind. When he begins to rise behind, he is to put the bridle-hand a little forwards to hold him before, and stay him there on the hand as if he hung in the air, timing the motion of the bridle-hand so, as to make him like a ball on the bound, which is the great secret in leaping.

STEPHEN, or *St. STEPHEN'S-DAY*, a festival of the Christian church, observed on the 26th of December, in memory of the first martyr St. Stephen.

STEREOGRAPHIC PROJECTION, is the projection of the circles of the sphere on the plane of some one great circle, the eye being placed in the pole of that circle. The method and practice of this projection in all the principal places, viz. on the planes of the meridian, equinoctial, and horizon, have already been given under the articles *MAP* and *PROJECTION*.

STEREOGRAPHY, the art of drawing the forms and figures of the solids upon a plane.

STEREOMETRY, *στερεομετρία*, that part of geometry which teaches how to measure solid bodies, i. e. to find the solidity or solid content of bodies, as globes, cylinders, cubes, vessels, ships, &c.

STEREOTOMY, the art or act of cutting solids, or making sections thereof, as walls or other members in the profiles of architecture.

STERILITY, the quality of a thing that is barren, in opposition to fecundity.

The word is formed from the Latin *sterilitas*, or *sterilis*, barren.

STERLING, a term frequent in English commerce, a pound, shilling, or penny, of lawful money of England, as settled by public authority.

STERNOHYOIDÆUS, in anatomy, a pair of muscles arising from the upper and internal part of the bone of the sternum.

STERNUM, in anatomy, the breast-bone, is situated in the middle of the breast, and is composed of seven or eight bones in infants, which at first are cartilaginous, but which harden and unite into three bones after they are seven years old; the substance of these bones is not solid, but somewhat spongy. The first and uppermost is the biggest and largest; it is uneven and rough on the outside, but smoother on its inside, where it has a shallow furrow, which gives way for the descent of the windpipe. It has a sinus lined with a cartilage on each side of its upper end, wherein it receives the heads of the claviculæ. The second is longer and narrower than the first, and on its sides, there are several sinus's in which the cartilaginous ends of the ribs are received. The third is shorter, but broader than the second. It receives into the lateral sinus's the extremities of the last two ribs; it terminates in a cartilage which hardens sometimes into a bone, called cartilago xiphoidis, or ensiformis, because it is broad at its upper end, where it joins

joins the third bone, and grows narrower to its extremity, where it is sometimes forked, and sometimes it bends inwards, compresses the upper orifice of the stomach, and causes a great pain and vomiting. The use of the sternum is to defend the heart, and to receive the extremities of the true ribs.

STERNUTATIVE, or **STERNUTATORY**, a medicine proper to produce sneezing.

STEW, a small kind of fish-pond, the peculiar office of which is to maintain fish, and keep them in readiness for the daily uses of a family.

STEWS, or **STUES**, were also places, anciently, permitted in England to women of professed incontinency for the proffer of their bodies to all comers. They were under particular rules and laws of discipline, appointed by the lord of the manor.

STEWARD, an officer appointed in another's stead or place, and always taken for a principal officer within his jurisdiction. Of these there are various kinds. The greatest officer under the crown is the lord high steward of England, an office that was anciently hereditary and permanent in the families of the dukes of Lancaster, till the time of Henry IV. But the power of this officer is so very great, that it has not been judged safe to trust it any longer in the hands of a subject, excepting only *pro hac vice*, occasionally: as to officiate at a coronation, at the arraignment of a nobleman for high treason, or the like. During his office, the steward bears a white staff in his hand, and the trial, &c. ended, he breaks the staff, and with it his commission expires. There is likewise a lord steward of the king's household, who is the chief officer of the king's court, has the care of the king's house, and authority over all the officers and servants of the household, except such as belong to the chapel, chamber, and stable.

There is also a steward of the Marshalsea, who has judicial authority. And in most corporations, and all houses of quality in the kingdom, there is an officer of the name and authority of a steward.

The steward of a ship is he who receives all the victuals from the purser, and is to see it well stowed in the hold; all things of that nature belonging to the ship's use are in his custody; he looks after the bread, and distributes out the several messes of victuals in the ship; he hath an apartment for himself in the hold, which is called the steward's room.

STIGMATA, in natural history, the apertures in different parts of the bodies of insects, communicating with the tracheæ, or air vessels, and serving for the office of respiration. Nature has given to these minute animals a much larger number of tracheæ and bronchia than to us; all the two winged and four winged flies, which have a single or undivided corcelet, to which their legs are all fixed, have also four stigmata in that corcelet, two on each side; they have them also on the rings of their body, but those on the corcelet are the most considerable. Of the four on the corcelet, the two anterior ones are usually the largest; these, as well as the posterior ones, are oblong, and placed obliquely to the length of the body. The colour of the stigmata frequently differs from that of the corcelet; some are yellowish, others of a coffee-colour, or some degrees of a fallow colour, in flies whose corcelet is brown, black, or blue. Flies have, beside these, several stigmata also in the rings of their bodies, perhaps in every one of them: these stigmata are not like those of the corcelet, but are round, usually a little eminent above the rest of the surface, and resembling a pin's head.

STIGMATA, in antiquity, certain marks impressed on the left shoulders of the soldiers when listed.

STIGMATA were also kinds of notes or abbreviations, consisting only of points disposed various ways, as in triangles, squares, crosses, &c.

STIGMATIZING, among the antients, was inflicted upon slaves, as a punishment, but more frequently as a mark to know them by, in which case it was done by applying a red-hot iron marked with certain letters to their foreheads, till a fair impression was made, and then pouring ink into their furrows, that the inscription might be the more conspicuous. Stigmatizing, among

some nations, was, however, looked upon as a distinguishing mark of honour and nobility.

STIL de Grain, in the colour-trade, the name of a composition used for painting in oil or water, and is made by a decoction of the lycium or Avignon-berry in alum-water, which is mixed with whiting into a paste, and formed into twisted sticks. It ought to be chosen of a fine gold-yellow, very fine, tender and friable, and free from dirt.

STILE, *Stilus*. See the article **STYLE**.

STILES, in carpentry, denote the upright pieces which go from the bottom to the top of any wainscot, or the like.

STILLATITIOUS OILS, such as are produced by distillation, in opposition to those got by infusion, expression, &c.

STILL-BOTTOMS, in the distillery, a name given by the traders to what remains in the still after the working the wash into low wines. These bottoms are procured in the greatest quantity from the malt wash, and are of so much value to the distiller, in the fattening of hogs, &c. that he often finds them one of the most valuable articles of the business.

The liquor left behind in the still, after the rectifying the low wines into proof-spirit, is also called by some by the name of still-bottoms; but this is little more than mere phlegm, or water impregnated with a few acid and oily parts, not worth separating, unless for curiosity. The liquor left in the still, after the rectifying the proof-spirit into alcohol, is also of the same kind.

The bottoms of melasses spirits seem calculated for many uses. It is very probable that the vinegar-makers would find their account in the trying them; and the strong and lasting yellow colour, with which they tinge the hands, may recommend them to the dyers. A small proportion of them, added to the new treacle to be fermented, greatly promotes the operation, and increases the quantity of spirit.

The bottoms of the wine spirit, that is, the remainder, after distilling the spirituous part from damaged wines, or wine lees, may be brought to afford Mr. Boyle's acid spirit of wine, and that substance called by Becher the *media substantia vini*. A parcel of tartar may also be procured in very great perfection; and the last remainder may be converted into excellent and genuine salt of tartar. This liquor may likewise be serviceable in making vinegar and white lead.

STILL-HOUSE. The Dutch have much the advantage of us in the structure of their still-houses. The general rules in building those houses, according to Shaw, should be such as follow. The first caution is, to lay the floor aslope, not flat, where any wet work is to be performed. It should also be well flagged, with broad stones, so that no wet be detained in the crevices, but all may run off, and be let out at the drains made at the bottom and sides. The stills should be placed abreast on that side of the still-house to which the floor has its current. Fronting the stills, and adjoining to the back of the wall should be a stage for holding the fermenting backs, and these being placed at a proper height, may empty themselves by means of a cock and a canal into the stills, which are thus charged with very little trouble. Near this set of fermenting backs should be placed a pump or two, that may readily supply them with water, by means of a trunk, or canal, leading to each back; under the pavement adjoining to the stills should be a kind of cellar, wherein to lodge the receivers, each of which should be furnished with its pump, to raise the low wines into the still for rectification; and through this cellar the refuse wash, or still bottoms, should be discharged by means of a hose, or other contrivance.

STIMULATING, *Stimulans*, a property in angular or sharp bodies, whereby they vellicate and cause vibrations and inflections of the fibres of the nerves, and a greater derivation of nervous fluid into the parts affected. Stimulants produce pain, heat, redness, &c. They may be reduced to violent penetrating depilatories, gentle sinapisms, vesicatories, and caustics.

STING, *Aculeus*, an apparatus in the body of certain insects, in form of a little spear, serving them as a weapon

pon of offence. The sting of a bee or wasp, is a curious piece of mechanism; it consists of a hollow tube, at the root whereof there is a bag full of sharp, penetrating juice, which in stinging, is injected into the flesh, through the tube; within the tube, Mr. Durham has observed, there lie two sharp small bearded spears: in the sting of a wasp, he told eight beards on the side of each spear somewhat like the beards of fish-hooks. One of these spears in the sting, or sheath, lies with its point a little before the other, to be ready, as should seem, to be first darted into the flesh, which once fixed by means of its foremost beard, the other then strikes too, and so they alternately pierce deeper and deeper, their beards taking more and more hold in the flesh; after which the sheath or sting follows to convey the poison into the wound, which that it may pierce the better, is drawn into a point with a small slit below that point for the two spears to come out at. By means of these beards it is, that the animal is forced to leave its sting behind it, when disturbed, because it can have no time to withdraw the spears into the scabbard.

STINK, or **STENCH**, a disagreeable smell exhaling from a corrupted, or other body, and which is prejudicial to the nose and brain. A stinking breath is usually the result either of diseased lungs, or else of scorbutic gums, &c. A stinking nose is the result of a deep ulcer within the nose, whence arise fetid scales, &c.

STIPEND, *Stipendium*, among the Romans, signified the same with tribute; and hence stipendiarii were the same with tributarii.

STIPULATION, in the civil law, the act of stipulating, that is, of treating and concluding terms and conditions to be inserted in a contract. Stipulations were anciently performed at Rome, with abundance of ceremonies; the first whereof was, that one party should interrogate, and the other answer, to give his consent, and oblige himself. By the ancient Roman law, no body could stipulate but for himself; but as the tabelliones were public servants, they were allowed to stipulate for their masters, and the notaries, succeeding the tabelliones, have inherited the same privilege.

STOCKING, that part of the cloathing of the leg and foot which immediately covers their nudity, and screens them from the cold.

Anciently, the only stockings in use were made of cloth or milled stuff sewed together; but since the invention of knitting and weaving stockings of silk, wool, cotton, thread, &c. the use of cloth stockings is quite laid aside.

The modern stockings, whether wove or knit, are a kind of plexus's formed of an infinite number of little knots, called stitches, loops, or masses, intermingled in one another.

Knit stockings are wrought with needles made of polished iron or brass wire, which interweave the threads and form the masses the stocking consists of. This operation is called knitting, the invention of which is commonly attributed to the Scots, on this ground, that the first works of this kind came from thence. It is added, that it was on this account that the company of stocking-knitters established at Paris, in 1527, took for their patron St. Fiacre, who is said to be the son of a king of Scotland. Woven stockings are ordinarily very fine; they are manufactured on a frame, or machine of polished iron, the structure and apparatus of which being exceedingly ingenious, are represented in plate CXXIII. *fig. 1.* where A is the jack for the bobbins to turn upon; B is the fizer, or woman whose business it is to twist the threads as they shall best suit the frame, in which the work is to be performed; C, the rices which wind the hanks or skains upon the bobbins for the use of the fizer; D, the winder; and E the stocking-frame, or engine, with the maker at work. 1. Are the treddles, like those of other sorts of looms; 2. is the bobbin of twisted silk, &c. fixed on the bobbin-wire, which it turns with ease to feed the engine; 3. is the wheel, by whose motion the jacks are drawn together upon the needles; 4. is the silk, &c. which runs off the bobbin, and is in that posture directed up to the needle to be looped; 5. is the needle on which the stockings are made according to art.

The English and French have greatly contested the honour of the invention of the stocking-loom; but we are assured, whatever pretensions the French claim to this invention, that the same was certainly devised by William Lee, of St. John's college, Cambridge, in the year 1589, though it is true, that he first made it public in France, after despairing of success in his own country.

STOICS, a sect of antient philosophers, the followers of Zeno, thus called from the Greek, *στοα*, which signifies a porch or portico, in regard Zeno used to teach under a portico or piazza.

It was the common fault of the Stoics to introduce abundance of subtilty and dryness into their disputations, either by word of mouth, or in writing. They seemed as carefully to avoid all beauty of stile, as depravity of morals. Chrysippus, who was one of the Stoics, did no great honour to his sect, and could only disgrace it. He believed the gods perishable, and maintained, that they would actually perish in the general conflagration. He allowed the most notorious and most abominable incests, and admitted the community of wives amongst sages.

To the praise of the Stoics in general, it must, however, be confessed, that, less intent than other philosophers upon frivolous, and often dangerous speculations, they devoted their studies to the clearing up of those great principles of morality which are the firmest supports of society; but the dryness and stiffness that prevailed in their writings, as well as in their manners, disgusted most of their readers, and abundantly lessened their utility. Zeno's chief followers, among the Greeks, were Lucippus, Cleanthus, Chrysippus, Diogenes Babylonius, Antipater, Panætius, Possidonius, and Epicetetus. Among the Romans, Cato, Varro, Cicero, Seneca, the emperor Antoninus, &c. The Stoics cultivated logic, physics, metaphysics, &c. but especially ethics. The principal of their dogmata, of the former kinds, are, that there are certain catalepsias or comprehensions, called also *νοηται εννοιας*, innate ideas or principles, naturally found in the mind; that God is the seminal cause of the universe, and with the Platonist, that the world is an animal, by reason of God's inhabiting and informing every part thereof; that nature is an artificial fire tending to generation; and that the world is at last to be destroyed by a conflagration. As for the morality of the Stoics, it was couched much in paradoxes; as that a wise man is void of all passions, or perturbation of mind; that pain is no real evil, but that a wise man is happy in the midst of torture, is always the same, and is always joyful; that there is none else free; that none else ought to be esteemed king, magistrate, poet, or philosopher; that all wise men are great men; that they are the only friends or lovers; that nothing can happen to them beyond their expectations; that all virtues are insensibly connected together; that all good things are equal, and equally to be desired; that goodness admits of no increase or diminution. They own but one God, whom they, however, call by various names, as Fate, Jupiter, &c. by which they did not mean various things, but various powers and relations of the same thing. Providence they expressed under the name Fate, which Chrysippus defines to be a natural series, or composition of things mutually following each other, by an immutable nexus, or tie, fixed from all eternity. They held the immortality of the soul.

STOLE, *Stola*, a sacerdotal ornament wore by the Romish parish priests over their surplice, as a mark of superiority in their respective churches; and by other priests, over the alb, at celebrating of mass, in which case it goes a cross the stomach; and by deacons, over the left shoulder, scarf-wise; when the priest reads the Gospel for any one, he lays the bottom of his stole on his head. The stole is a broad swath, or slip of stuff hanging from the neck to the feet, with three crosses thereon. The bishops anciently pretended, that the parish-priests were never to appear before them, but in their stole. In Flanders and Italy, they always preach in stoles; it is supposed to be a representation of the extremities of the long robe, wore by the high-priest of the Jews.

Groom of the STOLE, the eldest gentleman of his majesty's bed-chamber, whose office and honour it is to present and put on his majesty's first garment, or shirt, every morning, and to order the things in the chamber.

Order of the STOLE, an order of knights instituted by the kings of Arragon. Another military order, at Venice, is called the order of the golden stole; thus called from a golden stole, which those knights wore over their shoulder, reaching to the knee, both before and behind, a palm and a half broad. None are raised to this order but patricians, or noble Venetians. It is uncertain when either of these orders was instituted.

STOMACH, *Ventriculus*, in anatomy, a hollow, membranous, organical part of an animal, destined to receive the food, after deglutition, and convert it into chyle.

It lies immediately under the midriff, the liver covers a part of its right side, the spleen touches it on the left, and the colon at its bottom, to which also the cawl is tied. Its figure resembles a bag-pipe, being long, large, wide, and pretty round at the bottom, but shorter and less convex on its upper part, where it has two orifices, one at each end, which are somewhat higher than the middle between them. The left orifice is called *oesophagus*, to which the *oesophagus* is joined. By this orifice the aliments enter the stomach, where being digested, they ascend obliquely to the pylorus, or right orifice, which is united to the first of the intestines. At this orifice the tunics of the stomach are much thicker than they are any where else, and the inmost has a thick and strong duplicature, in form of a ring, which serves as a valve to the pylorus, when it contracts and shuts. The stomach is composed of four membranes or coats. The first and inmost is made of short fibres, which stand perpendicularly upon the fibres of the next coat: they are to be seen plainly towards the pylorus. When the stomach is distended with meat, these fibres become thick and short. Whilst they endeavour to restore themselves by their natural elasticity, they contract the cavity of the stomach for the attrition and expulsion of the aliments. This coat is much larger than the rest, being full of plaits and wrinkles, and chiefly about the pylorus: these plaits retard the chyle, that it run not out of the stomach before it be sufficiently digested. In this coat there are, also, a great number of small glands, which separate a liquor which besmears all the cavities of the stomach, and helps the concoction of the aliments; therefore, this coat is called *tunica glandulosa*. The second is much finer and thinner; it is altogether nervous; it is of an exquisite sense, and is called *nervosa*. The third is muscular, being made of straight and circular figures; the straight run upon the upper part of the stomach, between its superior and inferior orifices; and the circular run obliquely from the upper part of the stomach, to the bottom. Of these, the innermost descend towards the right side, and the outermost towards the left; so that by their action both ends of the stomach are drawn towards its middle, and the whole is equally contracted; by their contraction and continual motion, the attrition and digestion of the aliments is in a great measure performed. The fourth tunic is common, it comes from the peritonæum. The stomach sends veins to the porta, viz. the *gastrica*, *pylorica*, and *vas breve*, and branches to the *gastro-epiplois dextra* and *sinistra*, which are accompanied with branches of the *arteria cæliaca*, all which lie immediately under the fourth coat of the stomach. The eighth pair of nerves, or *par vagum*, give two considerable branches to the stomach, which, descending by the sides of the gullet, divide each into two branches, the external and internal. The two external branches unite in one, and the internal do so likewise; both which piercing the midriff, form, by a great number of small twigs, upon the upper orifice of the stomach and plexus, and then the internal branch spreads itself down to the bottom of the stomach; and the external branch spreads itself upon the inside about the upper orifice of the stomach. This great number of nerves which is about the upper orifice renders it very sensible, and from them also proceeds the great sympathy between the stomach, head, and heart; upon which account Van Helmont thought that the soul had

its seat in the upper orifice of the stomach. The plexus nervosi of the hypochondria and mesenterium give several branches to the bottom of the stomach; therefore in hysterical and hypochondriac passions the stomach is also affected.

STOMACHICS, are such medicines as are serviceable to the stomach, promote digestion, &c.

Stomachic corroboratives are such as strengthen the tone of the stomach and intestines, among which are carminatives, as the roots of galangals, red gentian, zedoary, pimpinella, calamus aromaticus, and arum. Of barks and rinds, those of canella alba, sassafras, citrons, Seville and China oranges, &c. Of spices, pepper, ginger, cloves, cinnamon, cardamums, and mace. Other things of this nature are, among simples, Roman and common chamæmile, wormwood, mint, carduus benedictus, and the four carminative seeds. Of preparations, the oil of cedar, oil of oranges by expression, oils of common chamæmile, daucus Creticus, anisum stellatum, cumin, caraway, mint, and wormwood, with the spirit of salt and sweet nitre. Among compounds, are the sal volatile sylvii, the stomachic elixir, the essence of orange peel, with sweet spirit of nitre, tincture of tartar, oils of oranges prepared by expression, the compound essence of wormwood, &c.

STOMACHIC, is also applied to the arteries, veins, &c. of the stomach.

STOMACHUS, in anatomy, the same with the *oesophagus*, or *gula*. See *OESOPHAGUS*.

STOMATIA, in natural history, a genus of simple shells, without any hinge, and formed of one piece; its figure is depressed and flat, its mouth the most patent of all the shells, the limpet only excepted; it has a short spiral turn running into the mouth, at the head; and has no perforations in any part of the surface. The animal inhabiting this shell is a *nereis*.

STOMATICA, a term used by some for all medicines used in disorders of the mouth and fauces.

STONE, in natural history, a hard solid body, neither malleable, fusible by fire, nor soluble in water; formed, by succession of time, in the bowels of the earth.

Mr. Tournefort supposes that stones vegetate; but M. Geoffroy accounts for the origin and formation of stones in a different manner. He lays it down as a principle, that all stones, without exception, have been fluid; or, at least, a soft paste, now dried and hardened.

On this principle he examines the formation of the different kinds of stones, and shews that the earth alone is sufficient for the same, independent of all salts, sulphurs, &c. Mr. Geoffroy conceives two kinds of primitive particles in the earth. Those of the first kind exceedingly fine, thin lamellæ, equal to each other, or nearly so. Now when these meet together, from any cause whatever, in a sufficient quantity, the regularity and equality of their figures determine them to range themselves equally and regularly; and thus to form a homogeneous compound, which is very hard, from the immediate contact of the parts; and very transparent, by reason of their regular disposition, which leaves a free passage to the rays of the light every way; and this is called crystal.

The parts of the second kind have all sorts of irregular figures, and must accordingly form assemblages that are much opaquer, and less hard. Now crystal is formed wholly of parts of the first kind, and all other stones of a mixture of the two kinds of parts together; this mixture is absolutely necessary, in order to unite and bind together the parts of the second kind, and give them a hardness and consistence, without which they would only make a sand or dust. Water appears the fittest vehicle, to carry the parts of the first kind. This is seen from several petrifying springs, which incrustate the pipes through which their waters are conveyed, or even solid bodies laid in them for some time. The water does not dissolve these earthy parts; it only keeps them in fusion, as it does the juices wherewith plants are nourished.

This water, thus charged with earthy particles of the first kind, M. Geoffroy calls the stony, or crystalline juice, of which those bodies are primarily formed.

STONE,

STONE, in medicine, a stony or terrestrial concretion in any of the urinary passages, which occasions a difficulty in making water, and a pain in the small of the back, or about the os pubis. When this collection is so large as to form one or more bodies, unable by reason of their size to pass through the conduits of urine, they frequently cause great pain, ulcers in the parts, and an intire suppression of urine; and, from the part where this obstructing matter happens to lodge, this distemper receives its denomination, as from the kidneys, bladder, ureters, or urethra.

This disorder, says Dr. Shaw, may sometimes have an hereditary cause; that is, the urinary passages may be naturally straighter than they ought to be; or the constitution may be naturally disposed to generate a stony matter; an obstructed perspiration, and a cold or moist air, may also give rise to it; for by means hereof the more heavy particles of the animal fluids will be detained in the body.

Another occasion of this distemper may be the use of such waters, as by running through various strata of the earth, are impregnated with stony particles. There are some wines too, and other liquors, which being either foul or not sufficiently fined down, or abounding in tartar, or other terrestrial corpuscles, may lay the foundation for the stone. Again, in persons subject to the asthma or gout, who have a weak digestion, viscid chyle, and stony concretions in the joints, there are manifest seeds of this distemper. In short, whatever can bring on an accumulation of earthy particles in the urinary passages, whether by obstructing or lessening the capacity of the canals, or by immediately or remotely producing the substance itself, will cause gravel, and in time the stone.

The symptoms of the gravel or stone are, frequently, a nausea and vomiting, with a numbness down the leg and thigh of the part affected; a pain fixed or moveable, great or less, in proportion to the bulk of impacted matter felt generally about the region of the loins, os pubis, and parts adjacent. This pain is very acute, and almost continual, when the gravel or stone remains at the head of the ureters; but begins to lessen, as it is protruded forwards. Sometimes when the stone is angular, or continues long fixed, the urine is bloody; and, generally in nephritic obstructions, it is thin, and made in a small quantity, especially at the beginning of the fit. Sometimes there happens a total suppression of it, in which case both the ureters may be obstructed.

When the obstructed matter is forced into the bladder, the urine is turbid, and comes away plentifully: and there appears in it much sand, and sometimes small stones; which when angular, are seldom voided without much pain; and when the paroxysm is violent, and of long continuance, there sometimes happens an entire suppression of stool so far, that cathartics lose their force; and sometimes too, though rarely, the terrestrial matter is deposited in such parts where the canals are lax and the circulation languid, so as at the same time to occasion both an arthritic and a nephritic fit. When a stone is lodged in the urethra, the pain generally proves exquisite, but limited to the part, where sometimes the stone will bulge outwards, and may be felt with the fingers.

All paroxysms, in case of a confirmed stone, are dangerous. An accumulation of sand in the kidneys or ureters, is less dangerous than a formed stone. A stone in the kidneys is of a worse consequence than in the ureters, and more or less so in proportion to its bigness. The largest stone, naturally capable of passing the urethra in men, is supposed to be about the size of a small hazel nut; but in women, one considerably larger may pass the meatus urinarius. When both kidneys, or both ureters, are affected, it is so much the more dangerous, especially if attended with sharp pain, exulceration, inflammation, want of sleep, loss of strength, a fever, suppression of urine, &c. When the symptoms continue many days without intermission, the case is desperate; especially if coldness has seized the extremities, the pulse ticks, and the patient has cold sweats, &c. When the case is habitual or hereditary, or happens in old age or gouty constitutions, it is difficult.

The symptoms of bloody urine, continuing after the fit is gone off, prove hard to remove. When the urine is plentifully discharged, has its ordinary sediment, is turbid, and the symptoms decrease, it is a sign the paroxysm is going off. If a large stone be long detained in the urethra, especially if it be rugged, and can neither be propelled backwards nor forwards, and there be a total suppression of urine, the case usually proves mortal.

As to the method of cure, it consists in the easy exclusion of the stone, and the preventing the breeding of others. To this purpose, Sydenham recommends bleeding, a posset-drink, in which two ounces of marsh-mallow roots have been boiled, and an emollient clyster; after which, he advises a pretty large dose of an opiate; that is, about twenty-five drops of the thebaic tincture, or fifteen grains of the saponaceous pills. And Huxham tells us, that nothing is so efficacious to ease the pain, and promote the descent of the stone through the ureters, as a tepid and emollient bath. Dr. Mead assures us, that it is an error in practice, to give strong forcing diuretics, with a view of driving out the gravel with the urine: whereas this intention is answered with greater safety, in most cases, by relaxing and lubricating medicines; especially if, in case of violent pain, bleeding be premised, and anodynes interspersed. He therefore advises, to give three or four grains of opium, dissolved in five or six ounces of the common decoction, by way of clyster. However, he allows, there are conjunctures, after the pain is abated, when powerful diuretics may be administered; but with this precaution, that as soon as they have had their effect, they are no longer to be continued. All this time the body should be kept open, by giving a turpentine clyster, and sometimes purging gently with an infusion of senna and manna, because strong cathartics are to be avoided.

The chief lubricating medicines are oil of sweet almonds, syrup of marsh-mallows, emulsions made with almonds, and the like; to which may be added the use of the warm bath. Soap and lime-water are also celebrated lithontriptics.

Such as have a stone in the bladder, should, while they are taking the foresaid medicines, have four ounces or upwards of tepid oyster shell lime-water injected into the bladder every day; taking care to evacuate their urine before injection, and to retain it as long as they can without pain. And were it not for the trouble of introducing the catheter, the injection might be made at least twice every day; and if a flexible catheter were always kept in the bladder, it might be done at pleasure, and the dissolution of the largest stone quickly procured. The lime-water will be safer, and yet lose nothing of its virtue, if a dram of starch, or the fourth part of the yolk of an egg, be boiled in six or seven ounces of it.

Those who, though they have no stone in the bladder, are nevertheless frequently troubled with fits of the gravel in the kidneys, may probably put a stop to the disorder, by drinking every morning a pint of oyster-shell lime-water, two or three hours before breakfast. Its disagreeable taste may be mitigated, by adding a very small quantity of new-milk to it; also a dram and a half, or two drams, of juniper-berries, infused in every quart-bottle of it, will mend its taste much.

As to the regimen to be observed, Dr. Mead recommends a mild diet, and such as is easy of digestion; and wine and water, mead, or new soft ale, for drink; and gentle exercise, especially riding.

STONE also denotes a certain quantity or weight of some commodities.

A stone of beef at London, is the quantity of eight pounds; in Herefordshire twelve pounds; in the north, sixteen pounds.

A stone of wool, according to the statute of 11 Hen. VII. is to weigh fourteen pounds; yet in some places it is more, in others less; as in Gloucestershire fifteen pounds; in Herefordshire twelve pounds.

A stone among horse-courers, is the weight of fourteen pounds.

STONEHENGE, in antiquity, a famed pile or monument

ument of huge stones in Salisbury plain, six miles distant from that city. It consists of the remains of four ranks of rough stones, ranged one within another, some of them, especially in the outermost and third rank, twenty feet high, and seven broad; sustaining others laid across their heads and fastened by mortises: so that the whole must have anciently hung together.

Antiquaries are now pretty well agreed that it was a British temple; and Dr. Langwith thinks it might easily be made probable at least, it was dedicated to the sun and moon. Inigo Jones has given a fine scheme of the work, and strives hard to persuade the world, that it was Roman: but Dr. Langwith, who took his measures on the spot, assures us he could by no means reconcile them with that scheme.

STONE BRASH, in agriculture, is a light lean soil, full of larger and smaller masses of rubble stones.

These are to be tilled according to the condition in which they are found, for if they are grassy they fallow them pretty late; but, if they have no grass upon them, they fold them in winter, when the sheep's dung, with the help of some hay-seed, will furnish them with grass; or else, early in the spring, they lay upon them old thatch or straw, or the strawy part of old dunghills, earth out of ditches, or the like, which will all, more or less, help forward a coat of grass upon the land; for it is a rule, in regard to these lands, that they must have a covering of grass before they are fallowed, else they will yield but a poor crop.

STONY-LANDS, in agriculture, such as are full of flints, pebbles, or small fragments of free-stone.

These lands in many places yield good crops, and the general rule is, that in stiff and cold lands the stones should be as carefully picked out as may be, but in light and dry grounds they should be left. In Oxfordshire they have great quantities of a lean earth, and a small rubble-stone, or a four sort of land mixed with it; this is sometimes very full of weeds, and sometimes very clear of them: if they are weedy, they fallow them late; but if they be seary, as they express it, that is, if they have sward upon them, they either fold them in winter, and add some hay-seed to the sheep's dung, to bring up grass; or else they lay old thatch, or straw, and dung upon it; for they reckon, that if these lands have no sward upon them before they are fallowed, they will by no means be brought to bear a good crop, but a great deal of May-weed, and other unprofitable herbs. In September, November, and December, they fallow as the sward directs them: if this is done in either of the two last months, they call it a winter fallowing, and never stir it again till they plough it, and sow it with barley; and these lands are reckoned to do better than if finely tilled. They will bear wheat and meslin in a kindly year, and large crops of barley, if they are well managed, and kept in good heart.

They always fallow these lands every other year, unless they sow pease upon them; sometimes they sow them with lentils; and, when they are quite worn out, they lay them down for clover, or rye-grass.

STOOMING of *Wine*, is the putting bags of herbs, or other ingredients, into it. See *WINE*.

STOOPING, in falconry, is when a hawk being upon the wing, at the height of her pitch, bends down violently to take the fowl.

STOP, in the manege, is a pause, or discontinuance of a horse's motion.

To form a stop, you must, in the first place, bring to the calves of your legs to animate him, bend your body backwards, raise the bridle-hand without moving the elbow, then vigorously extend your hams, and rest upon your stirrups, and make him form the times or motions of his stop, in falcading his haunches three or four times. After stopping your horse, make him give three or four curvets. The opposite term of stop, is parting. In former times, the stop of a horse was called parade.

Half a stop, is a stop not finished, but a pefate; so that the horse, after falcading three or four times upon the haunches, resumes and continues his gallop, without making pefades or corvets.

STOPS, or POINTS, in grammar. See the articles *POINTING* and *PUNCTUATION*.

STORAX, or STYRAX, in the materia medica, an odoriferous resin exuding in the warmer climates, from a middling sized tree, with leaves like those of the quince, flowers like those of the orange tree, and fruit like filberds; a native of Asia, and, as it is said, of Italy. Two sorts of this resin have been commonly distinguished in the shops.

1. Storax in the tear, not in separate tears, or exceeding rarely, but in masses, sometimes composed of whitish and pale reddish brown tears, and sometimes of an uniform reddish-yellow or brownish appearance; unctuous and soft like wax, and free from visible impurities. This is supposed to be the sort which the ancients received from Pamphylia in reeds or canes, and which was thence named calamita.

2. Common storax, in large masses, considerably lighter and less compact than the foregoing, and having a large admixture of woody matter like saw-dust. This appears to be the kind intended by the London college, as they direct their styrax calamita to be purified, for medicinal use, by softening it with boiling water, and pressing it out from the feces betwixt warm iron plates; a process which the first sort does not stand in need of. And indeed there is rarely any other than this impure storax to be met with in the shops.

The writers on the materia medica in general prefer the pure storax in the tear, and reject that which is mixed with woody matter. It appears however, upon comparison, that this last, notwithstanding its large proportion of impurities, is the most fragrant of the two: nor is it difficult to assign a reason for this superiority, as the pure juice must have required, for its inspissation to a firm consistence, a longer exposure to the sun and air, and consequently lost more of its volatile parts, than when absorbed and thickened by the woody substance.

Common storax, infused in water, imparts to the menstruum a gold yellow colour, some share of its smell, and a slight balsamic taste. It gives a considerable impregnation to water by distillation, and strongly diffuses its fragrance when heated, though it scarcely yields any essential oil. Hence, in the purification of it by straining, it is apt to suffer a considerable loss of its finer matter, which is partly dissipated by the heat, and partly kept dissolved by the water: a part of the storax is likewise defended by the woody substance from the action of the press, and left behind among the feces. It may be purified rather more elegantly by means of rectified spirit, which readily dissolves the fine resin, leaving only the impurities and a little inert gummy matter: the spirit gently distilled off from the filtered reddish-yellow solution, brings over with it very little fragrance of the storax; and the remaining is more fragrant than the finest storax in the tear which we have met with. The pure resin, distilled without addition, yields, along with an empyreumatic oil, a portion of saline matter similar to the flowers of benzoine, and sometimes also a substance has been extracted from it of the same nature by coction in water.

Storax is one of the most agreeable of the odoriferous resins, of a mild taste, of no great heat or pungency, nearly similar, in its medical as in its pharmaceutic qualities, to benzoine and balsam of Tolu. It is not, however, much used in common practice, unless as an ingredient in some of the old compositions, and in an opiate pill to which it gives name in the shops.

Liquid STORAX, a resinous juice, obtained from a large tree, with angular leaves like those of the maple, and a round fruit composed of a number of pointed seed-vessels, called by Ray *styrax aceris folio*, a native of Virginia and Mexico, and lately naturalized to our own climate. The juice called liquid amber is said to exude from incisions made in the trunk of this tree, and the liquid storax to be obtained by boiling the bark or branches in water.

Two sorts of liquid storax are distinguished by authors: one, the purer part of the resinous matter that rises to the surface in the boiling, separated by a strainer, of the consistence of honey, tenacious like turpentine, of a reddish or ash-brown colour, of an acrid unctuous taste, and a fragrant smell, resembling that of the solid storax, but

but somewhat disagreeable: the other, the more impure part, which remains on the strainer, in smell and taste much weaker, and containing a considerable proportion of the substance of the bark. What is most commonly met with under the name in the shops, is of a weak smell, and a grey colour, and is supposed to be an artificial composition.

STORGE, *στοργή*, a Greek term, frequently used for the parental instinct, or natural affection, which almost all animals bear their young; whereby they are most powerfully moved to defend them from dangers, and procure for them suitable nourishment.

STOVES, in gardening, are buildings erected for the preservation of tender exotic plants, which will not live in these northern countries, without artificial warmth in winter. These are built in different methods, according to the ingenuity of the artist, or the different purposes for which they are intended; but in England they are at present reducible to two.

The first is called a dry stove, being so contrived, that the flues through which the smoke passes are either carried under the pavement of the floor, or else are erected in the back-part of the house, over each other, and are returned six or eight times the whole length of the stove. In these stoves the plants are placed on shelves of boards laid on a scaffold above each other, for the greater advantage of their standing in light, and enjoying an equal share of light and air. In these stoves are commonly placed the tender sorts of aloes, cereus's, euphorbiums, tithymals, and other succulent plants, which are impatient of moisture in winter; and therefore require, for the most part, to be kept in a separate stove, and not placed among trees, or herbaceous plants, which perspire freely, and thereby often cause a damp air in the house, which is imbibed by the succulent plants, to their no small prejudice.

These stoves may be regulated by a thermometer, so as not to over-heat them, nor to let the plants suffer by cold; in order to which, all such plants, as require nearly the same degree of heat, should be placed by themselves in a separate house; for, if in the same stove there are plants placed of many different countries, which require as many different heats, by making the house warm enough for some plants; others, by having too much heat, are drawn and spoiled.

The other sorts of stoves are commonly called bark stoves, to distinguish them from the dry stoves already mentioned. These have a large pit, nearly the length of the house, three feet deep, and six or seven feet wide, according to the breadth of the house; which pit is filled with fresh tanners bark, to make an hot-bed; and in this bed the pots of the most tender exotic trees, and herbaceous plants, are plunged: the heat of this bed being moderate, the roots of the plants are always kept in action; and the moisture, detained by the bark, keeps the fibres of their roots in a ductile state, which, in the dry stove, where they are placed on shelves, are subject to dry too fast, to the great injury of the plants. In these stoves, if they are rightly contrived, may be preserved the most tender exotic trees and plants, which, before the use of the bark was introduced, were thought impossible to be kept in England; but, as there is some skill required in the structure of both these stoves, we shall describe them as intelligibly as possible, particularly the bark stove; by which it is hoped every curious person will be capable of directing his workmen in their structure.

The dimension of this stove should be proportioned to the number of plants intended to be preserved, or the particular fancy of the owner; but their length should not exceed forty feet, unless there are two fire-places; and, in that case, it will be proper to make a partition of glass in the middle, and to have two tan-pits, that there may be two different heats for plants from different countries, for the reasons before given in the account of dry stoves; and were I to erect a range of stoves, they should be all built in one, and only divided with glass partitions, at least, the half way towards the front; which will be of great advantage to the plants, because they may have the air in each division shifted by sliding the glasses of the partitions, or by opening the glass-

door, which should be made between each division, for the more easy passage from one to the other.

This stove should be raised above the level of the ground, in proportion to the driness of the place; for, if it be built on a moist situation, the whole should be placed upon the top of the ground; so that the brick-work in the front must be raised three feet above the surface, which is the depth of the bark-bed, whereby none of the bark will be in danger of lying in water; but, if the soil be dry, the brick-work in front need not be more than one foot above-ground, and the pit may be sunk two feet below the surface. Upon the top of this brick-work, in front, must be laid the plate of timber, into which the wood-work of the frame is to be mortised; and the upper timber in front must be placed four feet asunder, or somewhat more, which is the proportion of the width of the glass-doors or sashes: these should be about six feet and an half, or seven feet long, and placed upright; but from the top of these should be sloping glasses, which should reach within three feet of the back of the stove, where there should be a strong crown-piece of timber placed, in which there should be a groove made for the glasses to slide into. The wall in the back-part of the stove should be at least thirteen inches thick; but eighteen inches is still better; because, the thicker the out-side wall is built, the more the heat of the flues will be kept in the house; and carried up, about nine feet above the surface of the bark-bed; and, from the top of this wall, there should be a sloping roof to the crown-piece where the glasses slide in. This crown-piece should be about sixteen feet high from the surface of the bark-bed or floor, which will give a sufficient declivity to the sloping glasses to carry off the wet, and be of a reasonable height for containing many tall plants. The back-roof may be slated, covered with lead, or tiled, according to the fancy of the owner: for the manner of this outside building is often very various, and differently built.

In the front of the house there should be a walk, about eighteen or twenty inches wide, for the convenience of walking; next to which the bark pit must be placed, which should be in width proportionable to the breadth of the house: if the house is twelve feet wide, which is a due proportion, the pit may be seven feet wide; and behind the pit should be a walk eighteen inches wide, to pass in order to water the plants, &c. then there will be twenty-two inches left next the back-wall, to erect the flues, which must be all raised above the top of the bark-bed; these flues ought to be one foot wide in the clear, that they may not be too soon stopped with the soot; and the lower flue, into which the smoke first enters from the fire, should be two feet deep in the clear; and this may be covered either with cast iron plates, or broad tiles; over this the second flue must be returned back again; which may be eighteen inches deep, and covered on the top as before; and so, in like manner, the flues may be returned over each other three or four times, that the heat may be spent before the smoke passes off. The thickness of the wall in front of these flues need not be more than four inches; but it must be well jointed with mortar, and plaistered within to prevent the smoke from getting into the house; and the out-side should be faced with mortar, and covered with a coarse cloth, to keep the mortar from cracking, as is practised in setting up coppers. If this be carefully done, there will be no danger of the smoke entering the house, which cannot be too carefully avoided; for there is nothing more injurious to plants than smoke, which will cause them to drop their leaves; and, if it continue long in the house, will entirely destroy them.

The fire-place may be made either at one end, or in the middle, according as there is most convenience; for, where-ever it is placed, it should have a shed over it, and not be exposed to the open air; for it will be impossible to make the fire burn equally, where the wind has full ingress to it; and it will be troublesome to attend the fire in wet weather, where it is exposed to the rain.

The contrivance of the furnace must be according to the fuel which is designed to burn; but, as turf is the best firing for stoves, where it can be had, because it burns more moderately, and lasts longer, than any other

sort of fuel, and so requires less attendance, I shall describe a proper sort of furnace for that purpose.

The whole of this furnace should be erected within the house, which will be a great addition to the heat; and the front wall on the outside of the fire place, next the shed, should be three bricks thick, the better to prevent the heat from coming out that way. The door of the furnace, at which the fuel is put in, must be as small as conveniently may be to admit of the fuel; and this door should be placed near the upper part of the furnace, and made to shut as close as possible; so that there may but little of the heat pass off through it. This furnace should be about twenty inches deep, and sixteen inches square at bottom; but may be sloped off on every side, so as to be two feet square at the top; and under this furnace should be a place for the ashes to fall into, which should be about a foot deep, and as wide as the bottom of the furnace: this should also have an iron door to shut as close as possible; but just over the ash-hole, above the bars which support the fuel, should be a square hole about four inches wide, to let in air to make the fire burn: this must also have an iron frame, and a door to shut close when the fire is perfectly lighted, which will make the fuel last the longer, and the heat will be more moderate.

The top of this furnace should be nearly equal to the top of the bark-bed, that the lowest flue may be above the fire; so that there may be a greater draught for the smoke; and the furnace should be covered with a large iron plate, closely cemented to the brick work, to prevent the smoke from getting out; or it may be arched over with bricks; but you should be very careful, wherever the fire is placed, that it be not too near the bark-bed; for the heat of the fire will, by its long continuance, dry the bark, so that it will lose its virtue, and be in danger of taking fire; to prevent which, it will be the best method to continue an hollow between the brick-work of the fire and that of the pit, about eight inches wide; which will effectually prevent any damage arising from the heat of the fire; and there should be no wood-work placed any where near the flues, or the fire-place, because the continual heat of the stove may in time dry it so much, as to cause it to take fire; which ought to be very carefully guarded against.

The entrance into this stove should be either from a green-house, the dry stove, or else through the shed where the fire is made, because, in cold weather, the front-glasses must not be opened.

The other sort of stove, which is commonly called the dry stove, as was before said, may be either built with upright and sloping glasses at the top, in the same manner, and after the same model of the bark stove; or else the front-glasses, which should run from the floor to the ceiling, may be laid sloping, to an angle of forty-five degrees, the better to admit the rays of the sun in spring and autumn: the latter method has been chiefly followed by most persons who have built this sort of stoves; but, were I to have the contrivance of a stove of this kind, I would have it built after the model of the bark stove, with upright glasses in front, and sloping glasses over them, because this will more easily admit the sun at all the different seasons; for, in summer, when the sun is high, the top glasses will admit the rays to shine almost all over the house; and, in winter, when the sun is low, the front glasses will admit its rays; whereas, when the glasses are laid to any declivity in one direction, the rays of the sun will not fall directly thereon above a fortnight in autumn, and about the same time in spring; and, during the other parts of the year, they will fall obliquely thereon; and, in summer, when the sun is high, the rays will not reach above five or six feet from the glasses.

Besides, the plants placed towards the back-part of the house will not thrive in the summer-season for want of air; whereas, when there are sloping glasses at the top, which run within four feet of the back of the house; these, by being drawn down in hot weather, will let in perpendicular air to all the plants; and, of how much service this is to all sort of plants, every one who has had opportunity of observing the growth of plants in a stove, will easily judge: for, when plants are placed under co-

ver of a ceiling, they always turn themselves towards the air and light, and thereby grow crooked; and if, in order to preserve them straight, they are turned every week, they will nevertheless grow weak, and look pale and sickly, like a person shut up in a dungeon; for which reasons, I am sure, whoever has made trial of both sorts of stoves, will readily join with me to recommend the model of the bark stove for every purpose. *Miller's Gard. Diet.*

STOVE, among confectioners, denotes a little closet, well enclosed on all sides; wherein they dry their sweet-meats, ranged on several rows of shelves, made of wire.

STRABISMUS, *spasmus*. Squinting, in medicine and surgery, a distortion of the eyes, whereby their pupils are turned from, instead of being directed towards objects at which they look; sometimes only one eye, but more frequently both are thus affected.

This disorder is frequently caused in infants, from letting them constantly suck at one and the same breast; or from placing them in the cradle, so as that they always look the same way towards the light or window; by which repeated action, the muscles on that side become too strong to be ballanced by their opposite muscles; and hence the eye is contorted, or looks obliquely at objects. But it may be also owing to convulsive and epileptic motions, to which the eyes of infants are extremely subject. And, lastly, it may proceed, as well in adults as infants, from a spasm, or rigor, or from a palsy in some of the muscles of the eye; as also from a defect, or insensibility, of some part of the retina.

Squinting is a disorder very difficult to be cured, especially when in adults, and caused by some defect in the muscles, or retina: but, in young infants, it may probably be cured, says St. Yves, by frequently placing them before a looking-glass, that their eyes may be directed towards the image of their own face. Those more advanced in years may be assisted by reading very small writing or print; or by inspecting very minute objects, provided they turn their eyes even, and bathe them at times with hungary-water. Others propose to cure this disorder with a sort of mask, or eye-swath; but this method is seldom practicable, through the moroseness of infants, and other impediments.

STRAIGHT, STREIGHT, or STRAIT, in hydrography, a narrow sea, or gut shut up between lands on either side, and affording a passage out of one great sea into another.

STRAIN, or SPRAIN, a violent extension of the sinews or tendons of some muscle.

STRANGURY, in medicine, a partial suppression of urine; when it is total, it is called ischuria.

These cases are either true or spurious; true, if the suppression happens while the bladder is full; but spurious when, through some fault in the parts, there is no separation made of the urine, so that the bladder remains empty.

Paralytic or convulsive motions in the sphincter vesicae may cause these disorders. The neck of the bladder may be also too closely shut up by tumors, schirrhosities, inflammations, cistosities, caruncles, the stone, &c. The foetus likewise by pressing hard upon the neck of the bladder may give a rise hereto; the intestinum rectum being filled with indurated faeces, or the haemorrhoids being greatly swelled internally. This suppression may likewise happen from the urine being long detained; which distending the bladder may press its neck against the adjacent parts so hard, as to hinder the exclusion of its contents. A suppression of the urine also must necessarily ensue, when the serum of the blood is not duly separated, as in dropsies; so likewise in luxations of the vertebrae of the back in fevers; or when the kidneys or ureters are obstructed, &c. When this distemper proceeds from the stone, caruncles, tumors, &c. it is known by introducing the catheter. The other symptoms are easily discovered from the relaxation of the patient. If it proceed from inanition no tumor appears, there is a little pain, and the desire of making water returns less frequently, nor is there any weight or pressure perceivable in the abdomen; all which symptoms attend, when it proceeds from repletion.

An

An ischuria is more dangerous than a stranguria, and, if it continues long, proves always mortal; especially if it be from repletion, or when the spinal vertebræ are broke. The suppression continuing and hiccup supervening is accounted a sign of death.

As to the treatment, in order to obtund the acrimony of the blood, and take off the spastic motions, there is no medicine so useful as nitre, whether given alone, or mixed with some absterfivè salt, or with an absorbent, mixed with a small quantity of an acid to saturate it, and with a little cinnabar. A compound powder may be prepared of these ingredients, and a scruple of it given four times a day, will usually soon take off the complaint.

The cooling emulsions, made with barley-water and almonds, and with the cold seeds, are also of great service: and when there is farther occasion for medicines, gum arabic, and pills of boiled turpentine, are found very good ones; and decoctions of liquorice roots in barley-water, with syrup of marsh-mallows, may be drank in large draughts. Many people are also fond of external remedies, and recommend onions, roasted and buttered, to be applied to the pubes, and goat's suet to be rubbed warm about the navel.

A common strangury is often carried off by mere diluters, such as tea, barley-water, or any other watery liquor, drank in large quantities, till a sweat comes on; and in the gentler cases, where these alone are not quite effectual, there is no better addition to them than a little nitre.

Bleeding in time often prevents great mischiefs from these disorders; and in cases of a dysury, brought on by the taking cantharides, there is no remedy so powerful as warm milk alone, drank in large quantities. Mr. Boyle has also said much in favour of Venice-soap on this occasion.

STRAP, among surgeons, a strong piece of leather, or the like, used for stretching limbs, in the setting broken or dislocated bones.

STRAPS of a Saddle, are strong leather thongs, nailed to the bows of a saddle, in order to make the girths, &c. fast.

STRAPADO, or STRAPPADO, a kind of military punishment, wherein the criminal is hoisted up by a rope, and let down; so that, by the weight of his body in the fall, his arms are dislocated.

STRATA, in natural history, the several bodies or layers of different matters of which the body of the earth is composed.

The strata include all the layers of earths, minerals, metals, stones, &c. lying under the upper tegument or stratum, the turf, or mould,

The time when these several strata was laid was doubtless at the creation; unless with some great naturalists, as Steno, Dr. Woodward, &c. we suppose the globe of the earth to have been dissolved by the flood.

At that time, says Mr. Derham, whenever it was when the terrestrial globe was in a chaotic state, and the earthy particles subsided, then these several beds were repositied in that commodious order in which they are now found; and that, as is asserted, according to the laws of gravity, the lower still heavier than the upper.

But Dr. Leigh, in his natural history of Lancashire, speaking of the coal pits, denies the strata to be according to the laws of gravitation; observing that the strata there are first a bed of marle, then free-stone, next iron-stone, then coal, or channel mire, then some other strata, then coal again. This determined Dr. Derham to make a nicer enquiry into the matter; accordingly, in 1712, he caused divers places to be bored, laying the several strata by themselves, and afterwards determined very carefully their specific gravity. The result was that, in his yard, the strata were gradually specifically heavier and heavier, the lower and lower they went; but, in another place in his field, he could not perceive any difference in the specific gravities.

Acquainting the Royal Society therewith, their operator, Mr. Hawksbee, was ordered to try the strata of a coal pit, which he did to the depth of thirty strata: the thickness and specific gravity of each of which he gives

us in a table in the Philosophical Transactions, and from the whole makes this inference, that it evidently appears the gravities of several strata are in no manner of order, but purely casual, as if mixed by chance.

STRATAGEM, a military wile; or, a device in war for the surprising or deceiving the enemy.

The word is formed from the Greek *στρατηγία*, to lead or command an army.

STRATEGUS, in Grecian antiquity, an annual officer among the Athenians, of which there were two chosen, to command the troops of the state.

STRATIFICATION, in chemistry, the ranging any thing to be calcined in several layers or strata one above another; which operation is denoted by the abbreviation S. S. S.

STRAWBERRY, *Fragaria*, in botany. See FRAGARIA.

The common strawberry is frequent in the woods of England, and is thence transplanted into gardens. The best season for this is in September, that the plants may be rooted before the frosts. They may also be transplanted in February; but then, if the spring should prove dry, they will require a great deal of watering to keep them alive.

The proper soil for strawberries is a light hazely loam, not over rich; the ground must be well dug, and very carefully cleared of all noxious weeds; and, when it is levelled even, it should be marked out into beds about three feet and a half wide, leaving a path-way between each bed of two feet broad. In each of these beds should be planted four rows of plants, so that they may stand about a foot distance from each other in the rows, and they should be planted at about eight inches plant from plant in each. This is the proper distance for the wood strawberry, which is of the least growth of any; but the scarlet strawberry must be planted at a foot distance every way, and the hautboy sixteen inches; and, finally, the large Chili strawberry, which is the largest grower of all, must be set at twenty-two inches distance plant from plant.

In the spring, when the strawberries begin to flower, if the season is dry, they must be very plentifully watered, and they must be kept very carefully cleared from weeds. At Michaelmas the beds should be dressed, the weeds all very carefully taken up, all the strings or runners must be taken from the roots, and the weak plants, which stand too close, must be pulled up; throwing a little fine earth, at the same time, over the plants, also greatly strengthens their roots. These beds, however well managed, will not continue good above three years; and, the beds of the first year bearing but few fruit, it is necessary to new-plant some fresh ground every third year, and destroy the old beds; but the new ones must be first of one year's growth.

Different palates prefer different species of strawberries, but the white-fruited one is, of all others, the best flavoured; though it is but a very bad bearer. The great Chili strawberry is cultivated in the fields in that country; it is a much stronger and larger plant than any of our kinds, and its fruit is as large as a walnut, but not so well tasted as our own strawberries. Mr. Frezier brought them some years ago to Paris, and, since that, they have been spread over the several parts of Europe. They grow best in a loamy soil under the shade of trees. *Miller's Gard. Dict.*

STRENGTH, *vis*, in physiology, the same with force.

The strengths of different animals of the same species or of the same animal, at different times, are demonstrated to be in a triplicate proportion of the quantities of the mass of their blood; the whole strength of an animal is the force of all the muscles taken together; therefore, whatever increases strength, increases the force of all the muscles, and of those serving digestion as well as others.

STRENGTHENERS, in pharmacy, medicines that add to the bulk and firmness of the solids; and such are all absorbent, agglutinant, and astringent medicines.

STRÆ, in the ancient architecture, the lists, fillets, or rays which separate the striges or flutings of columns.

Among

Among naturalists, the term *striae* denotes the small channels and ridges in scollop-shells, &c.

STRICTOR, in anatomy, the same with constrictor and sphincter.

STRIKE, a measure of capacity, containing four bushels.

STROPHE, in the Greek and Latin poetry, a stanza or certain number of verses including a perfect sense; succeeded by another consisting of the same number and measure of verses, and in the same disposition and rhythmus, called *antistrophe*.

The work is Greek, *στροφή*, formed from *στρέφω*, to turn; because at the end of the strophe the same measures returned again; or rather, as the term related principally to the music or dancing, because at first coming in the chorus, or the dancers, turned to the left, and, that measure ended, they turned back again to the right.

STRUMÆ, in medicine, tumors arising most usually on the neck and throat; called also *scrophulæ*, and popularly the evil or king's evil.

STUC, or **STUCCO**, in building, a composition of white marble, pulverized and mixed with plaster of lime, the whole sifted and wrought up with water; to be used like common plaster. This is what Pliny means by *marmoratum opus*, and *albarium opus*.

STUFF, in commerce, a general name for all kinds of fabrics of gold, silver, silk, wool, hair, cotton, or thread, manufactured on the loom; of which number are velvets, brocades, mohair, sattins, taffeties, cloth, serges, &c.

STUM, in the wine-trade, denotes the unfermented juice of the grape, after it has been several times racked off, and separated from its sediment. The casks are for this purpose, well matched, or fumigated with brimstone every time, to prevent the liquor from fermenting, as it would otherwise readily do, and become wine.

It is this fume of the sulphur from the match, that prevents, in this case, all tendency to fermentation, and continues the natural juice of the grape in a sweet state, fit to be readily mixed with wines instead of sugar; for which purpose it is very much used in Holland, and some other countries; as also for giving a new fret, or briskness to decayed wines: so that very large quantities of this stum are annually imported to all parts, along with the foreign wines. And after the same manner a stum is prepared in England, from the juice of apples, which serves the ordinary purposes of the wine-cooper. In the preserving this liquor in this state, we see the vast use of brimstone, for it could never be done otherwise than by the matching of the casks.

Dr. Shaw gives the following method of preparing an artificial stum, nothing inferior to the natural; and as fit for the refermenting, fretting, improving, or making of wines, vinegars, and spirits. Take three pounds of fine lump-sugar, or such as has been well refined from its treacle; melt it in three quarts of water, and add, in the boiling, of Rhenish tartar, finely powdered, half an ounce; this dissolves with a remarkable ebullition, and gives a grateful acidity to the liquor: take the vessel from the fire, and suffer it to cool, and you have an artificial must, which in all respects resembles the natural taste and sweet juice of a white flavourless grape, when well purified, and racked off from its sediment, in order to make stum. If this artificial must be stummed, that is, well fumigated, with burning brimstone, it becomes a perfect stum, and may be made of any flavour, at the discretion of the artist.

STUPEFIERS, in medicine, the same with narcotics and opiates.

STUPOR, a numbness in any part of the body, whether occasioned by ligatures obstructing the blood's motion, by the palsy, or the like.

STURGEON, *Sturio*, a well known large and fine-tasted fish, caught in many places, and sometimes in the river Thames, being one of those fishes called *anadromi* by authors, which spend a part of their time in the sea, and a part in rivers.

It never goes into the sea to any great distance, and never is caught there of any very great size. The sea

serves for its production, but it is only in large rivers that it grows to its usual size.

STYE, or **STITHE**, a disorder of the eye-lids; being a small encysted tumor, about the bigness of a barley-corn.

The stye frequently occasions much pain and uneasiness, and must be treated with great caution, on account of the tenderness of the eye. Some recommend cataplasms, and the like applications; but the eye is often hurt by those; and it is observed besides, that these tubercles seldom give way to topical applications of any kind.

When they are small, Heister thinks it best to let them take their own course: but if so large as to occasion deformity, or danger of hurting the sight, the way to extirpate them, is to make a longitudinal incision on the part, and carefully take them out whole; or, if it cannot be thus got out clean, it must be cut out, as far as may be done, with scissars, and dressed with Ægyptian ointment, and a little red precipitate, or touched at times with the common caustic, till eaten thoroughly away, and then the wound dressed and healed in the common manner.

This is the method by which the flat and broad-bottomed tumours of this kind are to be extirpated; and in this, great care must be taken that none of the sharp applications touch the eye, as they might injure the sight. It is common, however, with these tumours to hang by a sort of small root, and then they are much more easily managed, there being no more necessary than the cutting them close off, with a pair of scissars, or the tying them firmly round with a piece of silk or horse-hair. They are sometimes, if taken in time, dispersed by rubbing them with fasting spittle, or by applying the pulp of a roasted apple mixed with some saffron and camphor.

STYGIAN LIQUORS, an appellation given to caustic and corrosive waters, and particularly to *aqua regia*.

STYLE, a word of various significations, originally deduced from *στυλ*, a kind of bodkin, wherewith the ancients wrote on plates of lead, or on wax, &c. and which is still used to write on ivory-leaves, and paper prepared for that purpose, &c.

STYLE, in dialling, denotes the gnomon or cock of a dial, raised on the plane thereof, to project a shadow.

STYLE, in matters of language, is the manner of expressing ourselves, or of cloathing our thoughts in words.

The matter ought to direct us in the choice of the style. Noble expressions render the style lofty, and represent things great and noble; but, if the subject be low and mean, sonorous words and pompous expression is bombast, and discovers want of judgment in the writer. Figures and tropes paint the motions of the heart, but to make them just, and truly ornamental, the passion ought to be reasonable. There is nothing more ridiculous than to be transported without cause, to put one's self in a great heat for what ought to be argued coolly: whence it is plain, that the matter regulates the style. When the subject or matter is great, the style ought to be sprightly, full of motion, and enriched with figures and tropes; if our subject contain nothing extraordinary, and we can consider it without emotion, the style must be plain.

The subject of discourse being extremely various in nature, it follows, there must be as great a variety in the style: but the masters of this art have reduced them all to three kinds, which they call the sublime, the low, and the intermediate.

Let the subject of which we design a lofty idea be never so noble, its nobleness will never be seen, unless we have skill enough to present the best of its faces to the view. The best of things have their imperfections, the least of which, discovered, may lessen our esteem, if not extinguish it quite: we must therefore take care not to say any thing in one place, which may contradict what we have said in another: we ought to pick out all that is most great and noble in our subject, and put that in its best light, and then our expression must be noble and sublime, capable of raising lofty ideas: and it is our duty

duty to observe a certain uniformity in our style; though all we say have not an equal magnificence, so far, at least, as to make all the parts of a piece bear a correspondence with the whole.

The danger here is, lest we fall into a puffy style, which some call inflation, or swelled; for, if we stretch things beyond their nature, and hunt only after great and sounding words, we seldom mind their agreeableness to the nature of the subject. And this has been the fault of many of our modern tragic writers, who yet with the vulgar have gained applause, and settled a reputation.

We come next to the plain or low style; and this simple and plain character of writing is not without its difficulties; not in the choice of subjects, those being always ordinary and common; but because there is wanting in this style that pomp and magnificence which often hide the faults of the writer, at least, from the general reader, or hearer. But on common and ordinary subjects there is little room for figures and tropes, so we must make choice of words that are proper and obvious. When we call the style simple and plain, we intend not meanness of expression; that is never good, and should always be avoided; for, though the matter or subject of this style have nothing of elevation, yet ought not the language to be vile and contemptible: mob-expressions, and vulgarisms, are to be avoided, and yet all must be clean and natural.

The intermediate, or middle style, consists of a participation of the sublime, on one side, and of simplicity of the plain, on the other. Virgil furnishes us with examples of all the three; of the sublime in his *Æneids*; the plain, in his *Pastorals*, and the mean, or middle, in his *Georgics*.

Though the style of an orator, or one that speaks in public, and of an historian and poet, are different, yet there are some differences in the styles of the same character; for some are soft and easy, others more strong; some gay, others more severe. Let us reflect on the differences, and how they are distinguished.

The first quality is easiness, and that is when things are delivered with that clearness and perspicuity, that the mind, without any trouble, conceives them. To give this easiness to a style, we must leave nothing to the hearer's or reader's decision; we must deliver things in their necessary extent, with clearness, that they may be easily comprehended; and here care must be taken of the fluency, and to avoid all roughness of cadence.

The second quality is strength, and it is directly opposite to the first; it strikes the mind boldly, and forces attention. To render a style strong, we must use short and nervous expressions, of great and comprehensive meaning, and such as excite many ideas.

The third quality renders a style pleasant and florid, and depends, in part, on the first; for the mind is not pleased with too strong an intention. Tropes and figures are the flowers of style; the first give a sensible conception to the most abstruse thoughts; figures awaken our attention, and warm and animate the hearer, or reader, by giving him pleasure. Motion is the principle of life and pleasure; but coldness mortifies every thing.

The last quality is severe: it retrenches every thing that is not absolutely necessary; it allows nothing to pleasure, admitting no ornaments or decorations. In short, we are to endeavour that our style have such qualities, as are proper to the subject of which we discourse.

STYLE, in music, denotes a peculiar manner of singing, playing, or composing; being properly the manner that each person has of playing, singing, or teaching; which is very different both in respect of different geniuses, of countries, nations, and of the different matters, places, times, subjects, passions, expressions, &c.

Old STYLE, in chronology, is a method of computing time introduced by Julius Cæsar, and which was followed in England, till the late reformation of the calendar.

New STYLE, is the manner of computing time introduced by pope Gregory, when he reformed the Julian

year; this is now followed in most countries of Europe.

STYLET, or **STILETTO**, a small dangerous kind of poniard, which may be concealed in the hand, chiefly used in treacherous assassinations. The blade is usually triangular, and so slender that the wound it makes is almost imperceptible. The stylet is prohibited in all well-disciplined states.

STYLOGLOSSUS, in anatomy, a muscle arising from the apex of the styloide process; and, descending obliquely to the side and root of the tongue, moves it sideways, backwards and forwards.

STYLOHYOIDÆUS, in anatomy, a pair of muscles arising from the styloide process, and terminating in the horn and the base: this is often perforated by the digastric muscle of the jaw. These muscles draw laterally upwards.

STYLOIDES, in anatomy, an apophysis of the os petrosum, thus called from its resembling a style or stylet.

STYLOPHARYNGÆUS, in anatomy, a pair of muscles, arising round and fleshy, from the process styloides; and which in its oblique descent becomes thicker, and is afterwards expanded on the back parts of the fauces. It serves to draw up and dilate the pharynx.

STYPTIC, *στυπτικόν*, in pharmacy, medicines which by their astringent qualities stop hæmorrhages.

When a considerable hæmorrhage is stoppt by absorbents or styptics, it is always produced by means of a clot of blood, secured by compression, so that the orifice of the vessel is stoppt. This clot generally consists of two parts, the one without, and the other within, the vessel: that without is formed by the last flowing blood, which, in coagulating, incorporates itself with the lint, moss, or powders, used for stopping the blood: the other part of the clot within the vessel, is only that portion of the blood which was ready to be discharged when the vessel was stoppt. These two parts are often but one continued clot. That without the vessel performs the office of a covering, whilst that within serves as a kind of stopper. Alcohol, or pure spirit of wine, is the most usual, and perhaps the best, styptic; and is the basis of most of the celebrated arcana for stopping hæmorrhages. Boerhaave says it becomes an immediate styptic, as it prevents putrefaction, and occasions a thin but very solid eschar. For if pledgets be dipped in pure alcohol, made hot, and applied to a bleeding wound, if it be closely compressed upon the part, and covered with a piece of bladder lightly besmeared with oil, and kept on with a proper bandage, the hæmorrhage presently ceases, and the whole dressing may continue unremoved for three days, in which time the vessels are usually closed, and strongly contracted and consolidated, by means of the alcohol.

The styptic powder of Helvetius is a medicine said to be serviceable in uterine hæmorrhages, either to correct the too frequent return of the menses, or their too great abundance; also to stop the flooding to which women with child are subject, and to moderate the flow of the lochia. It is also found to have very surprising good effects in the fluor albus. It is a composition of alum and dragon's blood: and in the Edinburgh dispensatory, two parts of alum are directed to be made into powder with one of the dragon's-blood: others use equal parts of both. Heister recommends this powder or alum alone, with a decoction of linseed.

Eaton's styptic is famous for curing fresh wounds in a very small time, and immediately stopping their bleeding: but Dr. Sprengel is said to prove, beyond all possibility of doubt, that this is in effect no other than the styptic of Helvetius.

The female agaric has been of late greatly celebrated as a styptic, and is said to restrain not only the venal but arterial hæmorrhages, without the use of ligatures.

SUB, a Latin preposition, signifying *under*, or *below*, frequently used in composition in our language: thus, 1. Sub-brigadier is an officer in the cavalry who commands under the brigadier, assisting him in the discharge of his office. 2. Sub-chantor, an officer in the choir, who officiates in the absence of the cantor. 3. Sub-deacon, an ancient officer in the church that was

made by the delivery of an empty platter and cup by the bishop; and of a pitcher, basin, and towel by the arch-deacon. His office was to wait on the deacon with the linnen whereon the body, &c. was consecrated, and to receive and carry away the plate with the offerings at the sacraments, and the cup with the wine in it, &c. 4. Sub-dean, a dignity in some chapters beneath the dean. 5. Sub-marshal, an officer in the Marshalsea that is deputy to the chief-marshal of the king's house, who is commonly called knight-marshal, and has the custody of the prisoners there. 6. Sub-prior, a claustral officer who assists the prior, &c.

SUBALTERN, a subordinate officer, or one who discharges his post under the command and subject to the direction of another: such are lieutenants, sub-lieutenants, cornets and ensigns, who serve under the captain; but custom has now appropriated the term to those of much lower ranks, as serjeants, and the like. We also say subaltern-courts, jurisdictions, &c. Such are those of inferior lords, with regard to the lord paramount; hundred courts, with regard to county-courts, &c.

SUBCLAVIAN, *Subclavius*, in anatomy, is applied to any thing under the arm-pit or shoulder, whether artery, nerve, vein, or muscle.

Subclavius more particularly denotes a small oblong muscle lying between the clavicle and first rib. It is fixed by one end in all the middle lower portion of the clavicle, at the distance of about an inch from each extremity, and by the other in the cartilage, and a small part of the bone of the first rib.

SUBCONTRARY POSITION, in geometry, is when two similar triangles are so placed, as to have one common angle at the vertex, and yet their bases not parallel.

SUBCOSTAL MUSCLES, *Subcostales*, in anatomy. These muscles are fleshy planes of different breadths, and very thin, situated more or less obliquely on the inside of the ribs, near their bony angles, and running in the same direction with the external intercostals. They are fixed by their extremities in the ribs, the inferior extremity being always at a greater distance from the vertebrae than the superior, and several ribs lying between the two insertions. These muscles are more sensible in the lower ribs than in the upper, and they adhere closely to the ribs that lie between their insertions.

SUBCUTANEOUS, in anatomy, a thin membranous muscle running under the skin, called also quadratus genæ, and platysma myoides. It arises with a pretty broad origin from the hind part of the neck, and from the pectoral muscle below the clavicle. It adheres firmly to the panniculus carnosus, from which it is not separated without difficulty, and therefore was not anciently distinguished from it; and is inserted obliquely on each side into the lower jaw-bone near the skin, lips, and sometimes the bottom of the nose, all which parts it draws downwards, and awry.

A convulsion herein is called a *spasmus cynicus*; in some persons it reaches to the ears, and in others not; which is the reason some folks have a faculty of moving their ears, which others want.

SUBDUPE Ratio, is when any number or quantity is contained in another twice—Thus, three is said to be subdupe of six, and six is dupe of three.

SUBDUPLICATE RATIO of any two quantities is the ratio of their square roots.

SUBJECT, *Subditus*, a person under the rule and dominion of a sovereign prince or state.

SUBJECT, *Subiectum*, is also used for the matter of an art or science, or that which it considers, or wherein it is employed. Thus the human body is the subject of medicine.

SUBJUNCTIVE, in grammar, the fourth mood or manner of conjugating verbs; thus called because usually joined to some other verb, or, at least, to some other particle, as, if “I loved, though this were true, &c.”

The Greek is almost the only language that properly has any subjunctive mood; though the French, Spanish, and Italian, have some shew thereof. In all other languages the same inflections serve for the optative and subjunctive moods; for which reason the subjunctive mood might be retrenched from the Latin, and those

other grammars; it not being the different ways of signifying, which may be very much multiplied, but the different inflections that constitute the different moods.

SUBLIMATE BODIES, a term used by some of our chemical writers to express such substances as are capable of sublimation in a dry form.

SUBLIMATE, a chemical preparation, the basis whereof is mercury or quicksilver. There are two kinds of sublimate; corrosive sublimate and sweet sublimate, or *mercurius dulcis sublimatus*.

SUBLIMATION, the condensing and collecting in a solid form by means of vessels aptly constructed, the fumes of bodies raised from them, by the application of a proper heat. Sublimation is in all respects the same with distillation, except that in the first the produce is solid, but in the latter fluid. The only variation therefore necessary in the operation is the accommodating the recipient part of the apparatus to this difference, which admits, in most cases, that one vessel may perform the office both of condenser and receiver, as the matter cannot, like fluids, flow to another part, but must remain where it first settles, except in some instances where the matter is extremely volatile, or where a fluid rising with it renders a depending receiver necessary.

The vessels proper, in respect of the different subjects of this operation, vary in their structure and the substance of which they are made, as well on account of the degree of heat requisite to be employed, as the nature of the matter to be sublimed, since corrosions of them are here, and indeed in all other cases, to be carefully avoided. In sublimations of mercury, whether combined with acids or sulphur, of *sal ammoniacum* and of sulphur alone, a single vessel may answer all the purposes, as their necessity of a great heat to keep them in the condition of fumes renders the upper part of the glass capable of detaining them when they are raised thereto; but it is proper, in these instances, that a glass in sand, or earthen ware, should be used. A glass body in a strong sand-heat may very well serve for all these; but sublimate of mercury is frequently sublimated in a bolt-head or matrafs; and the factitious cinnabar, by those who make large quantities, in an earthen vessel made in the shape of an egg. In the sublimation of volatile salts, salt of amber, and flowers of benjamin, a container and condenser are separately necessary, and they may, in all these cases, be extremely well supplied by a retort and receiver; though bodies with alembic heads, and receivers of glass fitted to them, have been generally recommended in several of them; but the luting two junctures, the difficulty of fitting them in each other, with several other reasons, make retorts far more convenient. A retort and receiver are likewise proper in the case of cinnabar of antimony; for, though the cinnabar might be easily restrained in one glass, the butter of antimony makes a receiver necessary.

In sublimation of factitious cinnabar, mercury sublimate and *sal ammoniacum*, &c. is sufficient to cover the aperture or neck of the vessels with a piece of tile, and, in the sublimation of cinnabar of antimony and flowers of benjamin in retorts, it is necessary to lute on the receiver; but, in the sublimation of volatile salts, it is requisite to lute the vessels as securely as possible, leaving only a small vent, till they attain the greatest heat they are to suffer during the operation.

The requisite degree of heat in sublimation varies in almost every different subject of the operation. The limits are from the greatest degree that can be given in sand, to a degree something less than that which will make water boil.

Hoffman observes, that only those things are sublimable which contain a dry exhaleable matter in their original construction; and among these is found a great variety, which require various methods and means to execute that effect.

Among the minerals, sulphur, antimony, and orpiment, are named as the principal sublimable bodies: these are of a very lax compage or structure, and easily raised by fire in small particles, which concrete again on being stopt from flying off by the cover of the vessel; while, on the contrary, iron, silver, and the other metals, being of a closer structure, remain fixed in the

greatest heat, and never ascend without being mixed with some volatile substance that is of itself capable of rising and taking up some of them with it.

Thus copper and iron will be raised in sublimation by means of sal ammoniac mixed with them; and even gold itself is said to be subject to the same law; Mr. Boyle assuring us that he had a secret method of preparing a certain saline substance, by means of a very small admixture of which, gold would be made to rise in sublimation, and form fine purple crystals.

The admixtures which make bodies sublimable that are not so in themselves, are to be of various kinds, according to the nature of the body to be sublimed. Among these some act by rendering the body more easily fusible, and disuniting those particles more readily which the fire is expected to carry up: others act again by preventing the cohesions of the particles of the substance to be sublimed, which heat would otherwise occasion: and, finally, others, by entering the body of the fixed substance they are mixed with, and giving wings, as it were, to its subtle particles, so that they may ascend with its easily sublimable matter, and join with it in the formation of one mixed substance in the top of the vessel, by partaking of the nature of both. Others act potentially in the same way, but by different means, themselves not being capable of sublimation, but acting on the substance to be sublimed, by enervating, weakening, or absorbing those substances, or parts, of the mixed body, which would otherwise have prevented the ascent of the rest; and, finally, some act as dissolvents only, and by that means render things easy of sublimation, which would have been very difficultly so, while their parts were in a more strict continuity.

SUBLIME, in discourse, is defined by Boileau, to be something extraordinary and surprising, which strikes the soul, and makes a sentiment or composition ravish and transport.

From this definition it appears, that the sublime is a very different thing from what the orators call the sublime style. The sublime style necessarily requires big and magnificent words; but the sublime may be found in a single thought, a single figure, a single turn of words. A thing may be in the sublime style and yet not be sublime; that is, it may have nothing extraordinary and surprising.

Longinus makes five sources of the sublime: the first, a certain elevation of the mind, which makes us think happily: the second is the pathetic, or that natural vehemence and enthusiasm which strikes and moves us; these two are wholly owing to nature, and must be born with us; whereas the rest depend partly on art: the third is the turning of figures in a certain manner, both those of thoughts and of speech: the fourth, nobleness of expression; which consists of two parts, the choice of words, and the elegant figurative diction: the fifth, which includes all the rest, is the composition and arrangement of the words in all their magnificence and dignity.

SUBLINGUAL GLANDS, in anatomy, two glands under the tongue, placed one on each side thereof. These, called also hypoglossides, filtrate a serous humour of the nature of saliva, which they discharge by little ducts near the gums into the mouth.

SUBMULTIPLE, in geometry, &c. A submultiple number, or quantity, is that which is contained a certain number of times in another, and which, therefore, repeated a certain number of times, becomes exactly equal thereto; thus 3 is a submultiple of 21; in which sense submultiple coincides with an aliquot part.

SUBMULTIPLE RATIO is that between the quantity contained and the quantity containing: thus the ratio of 3 to 21 is submultiple. In both cases submultiple is the reverse of multiple, 21, e. g. being a multiple of 3, and the ratio of 21 to 3 a multiple ratio. See the article RATIO.

SUBNORMAL, in geometry, a line which determines the point in the axis of a curve, where a normal, or perpendicular, raised from the point of contact of a tangent to the curve, cuts the axis. Or the subnormal is a line which determines the point wherein the axis is cut by a line falling perpendicularly on the tangent in the point

of the contact: thus T M plate CXXIII. fig. 2. being a tangent to a curve in M, and M R a normal or perpendicular to the tangent, the line P R intercepted between the semiordinate P M, and the normal M R, is called the subnormal. Hence 1. in a parabola, as A M, &c. the subnormal P R is to the semi-ordinate P M, as P M is to P T, and M R to T M. 2. In the parabola the subnormal P R is subduple the parameter, and, consequently, an invariable quantity.

SUBORDINATION, a relative term, expressing the degree of inferiority between one thing and another.

SUBORDINATION, a secret or underhand preparing, instructing, or bringing in a false witness, or corrupting or alluring a person to do such a false act.

SUBPŒNA, a writ, whereby any person, under the degree of peerage, is called to appear in Chancery, in cases where the common law has made no provision.

The name is taken from the words in the writ, which charge the party summoned to appear at the day and place assigned, *sub pœna centum librarum*, on the penalty of an hundred pounds.

SUBROGATION, or SURROGATION, in the civil law, the act of substituting in the place, and intitling him to the rights, of another.

SUBSCAPULARIS, in anatomy, a muscle arising from the basis and side of the scapula, and spreading itself under the whole convex, or under side of it; it is inserted by a semi-circular tendon into the os humeri, and draws it down to the side of the trunk.

SUBSCRIPTION in general signifies the signature put at the bottom of a letter, writing, or instrument.

In commerce, it is used for the share or interest which particular persons take in a public stock or trading company, by writing their names, and the shares they require in the books or register thereof.

Subscription, in the commerce of books, signifies an engagement to take a certain number of copies of a book going to be printed; and a reciprocal obligation of the bookseller or publisher to deliver the said copies on certain terms.

SUBSEQUENT, something that comes after another, particularly with regard to the order of time.

SUBSIDY, in law, signifies an aid or tax granted to the king, by parliament, for the necessary occasions of the kingdom; and is to be levied on every subject of ability, according to the rate or value of his lands or goods: but this word, in some of our statutes, is confounded with that of customs.

SUBSISTENCE, in the military art, is the money paid to the soldiers weekly, not amounting to their full pay; because their cloaths, accoutrements, tents, bread, &c. are to be paid. It is likewise the money paid to officers upon account, till their accounts be made up, which is generally once a year, and then they are paid their arrears.

SUBSTANCE, *Substantia*, something that we conceive to subsist of itself, independently of any created being, or any particular mode or accident.

Thus, a piece of wax is a substance, because we can conceive it as subsisting of itself, and of its own nature, without any dependance on any other created nature, or without any particular mode, form, colour, &c.

Spinoza maintains, that there is but one only substance in nature, whereof all created things are so many different modifications; and thus he makes the soul of the same substance with the body. The whole universe, according to him, is but one substance; which substance he holds endowed with an infinity of attributes, in the number of which are thinking and extension. All bodies are modifications of this substance, considered as extended; and all spirits modifications of the same substance, considered as thinking.

Mr. Locke's philosophy of substances is more orthodox. Our ideas of substance, that great author observes, are only such combinations of simple ideas, as are taken to represent distinct things, subsisting by themselves; in which the confused idea of substance is always the chief. Thus the combination of the ideas of a certain figure, with the powers of motion, thought, and reasoning, joined to substance, make the ordinary idea of man; and thus the mind observing several simple ideas to go

con-

constantly together, which being presumed to belong to one thing, or to be united in one subject, are called by one name; which we are apt, afterwards, to talk of and consider as one simple idea.

We imagine the simple ideas do not subsist by themselves; but suppose some substratum, wherein we subsist, which we call substance.

The idea of pure substance is nothing but the supposed, yet unknown support of those qualities which are capable of producing simple ideas in us.

The ideas of particular substances are composed out of this obscure and general idea of substance, together with such combinations of simple ideas, as are observed to exist together, and supposed to flow from the internal constitution, and unknown essence of that substance.

Thus we come by the ideas of man, horse, gold, &c. Thus the sensible qualities of iron, or a diamond, make the complex idea of those substances, which a smith, or a jeweller, commonly knows better than a philosopher.

The same happens concerning the operations of the mind, viz. thinking, reasoning, &c. which we concluding not to subsist by themselves, nor apprehending how they can belong to body, or be produced by it, we think them the actions of some other substance, which we call spirit; of whose substance or nature we have as clear a notion, as of that of body; the one being but the supposed substratum of the simple ideas we have from without; as the other of those operations, which we experiment in ourselves within: so that the idea of corporeal substance in matter is as remote from our conceptions, as that of spiritual substance.

Hence we may conclude, that he has the perfect idea of any particular substance, who has collected most of those simple ideas which exist in it; among which we are to reckon its active powers and passive capacities, though not strictly simple ideas.

Substances are generally distinguished by secondary qualities; for our senses fail us in the discovery of primary ones, as the bulk, figure, texture, &c. of the minute parts of bodies, on which their real constitutions and differences depend.—And secondary qualities are nothing but powers, with relation to our senses.

The ideas that make our complex ones of corporeal substances, are of three sorts: first, the ideas of primary qualities of things, which are discovered by our senses; such as bulk, figure, motion, &c. Secondly, the sensible secondary qualities, which are nothing but powers to produce several ideas in us, by our senses. Thirdly, the aptness we consider in any substance, to cause or receive such alterations of primary qualities, as that the substance so altered, should produce in us different ideas from what it did before; and they are called active and passive powers: all which, as far as we have any notice or notion of them, terminate in simple ideas.

Besides the complex ideas we have of material substances by the simple ideas taken from the operations of our own minds, which we experiment in ourselves, as thinking, understanding, willing, knowing, &c. co-existing in the same substance, we are able to frame the complex idea of a spirit; and this idea of an immaterial substance is as clear as that we have of a material one. By joining these with substance, of which we have no distinct idea, we have the idea of spirit; and by putting together the ideas of coherent, solid parts, and a power of being moved, joined with substance, of which likewise we have no positive idea, we have the idea of matter.

Further, there are other ideas of substances, which may be called collective; which are made up of many particular substances considered as united into one idea, as a troop, army, &c. which the mind makes by its power of composition. These collective ideas are but the artificial draughts of the mind, bringing things, remote and independent, into one view, the better to contemplate and discourse of them united into one conception, and signified by one name: for there are no things so remote, which the mind cannot, by this art of composition, bring into one idea; as is visible in that signified by the name universe.

SUBSTANTIAL, in the schools, something belonging to the nature of substance.

It is generally disputed, whether or no there be such things as substantial forms? i. e. forms independent of all matter; or forms that are substances themselves.

Substantial is also used in the same sense with essential, in opposition to accidental.

SUBSTANTIVE, in grammar, a noun, or name, considered simply and in itself, without any regard to its qualities, or other accidents, in contradistinction to the noun termed adjective, or that which expresses a certain quality or accident of the noun substantive. Or, a noun substantive is that noun, which, joined to a verb, makes a perfect sentence, as *a man, a horse, a tree*; thus *a man laughs, a horse gallops, a tree buds*, are each of them perfect sentences. All nouns, to which one cannot add the word *thing*, are substantives; and those to which *thing* may be added, are adjectives.

SUBSTITUTE, a person appointed to officiate for another, in case of absence, or other legal impediment.

SUBSTITUTE, in medicine, denotes a drug or remedy that may be used instead of another; or that supplies the place of another, of like virtue, which is not perhaps to be had: called also succedaneum.

SUBSTITUTION, in grammar, the using of one word for another, or one mode, state, person, or number of a word for another.—This the grammarians otherwise call syllepsis.

SUBSTITUTION, in algebra, &c. is the putting, in the room of any quantity in an equation, some other quantity which is equal to it, but expressed after another manner.

SUBTANGENT of a Curve, the line that determines the intersection of a tangent with the axis; or, that determines the point, wherein the tangent cuts the axis, prolonged.

Thus, the subtangent of the curve VMD plate CXXIII. fig. 3. is TP, determining the intersection of the tangent, and the axis or diameter continued.

In any equation, if the value of the subtangent comes out positive, it is a sign that the points of intersection of the tangent and axis fall on that side of the ordinate, where the vertex of the curve lies; as in the parabola and paraboloids: but, if it comes out negative, the point of intersection will fall on the contrary side of the ordinate, in respect of the vertex or beginning of the abscissa; as in the hyperbola and hyperboliform figures. And, universally in all paraboliform and hyperboliform figures, the subtangent is equal to the exponent of the power of the ordinate multiplied into the abscissa.

If CB fig. 4. be an ordinate to AB in any given angle terminating in any curve AC, and $AB = x$, $BC = y$, and the relation between x and y , that is, the nature of the curve, be expressed by this equation, $x^3 - 2xxy + bxx - bby + byy - y^3 = 0$, then this will be the rule of drawing a tangent to it: multiply the terms of the equation by any arithmetical progression; according to the dimensions of y , suppose

$x^3 - 2xxy + bxx - bby + byy - y^3$; as

0 1 0 0 2 3
also according to the dimensions of x , as,

$x^3 - 2xxy + bxx - bby + byy - y^3$
3 2 2 1 0 0
the former product shall be the numerator, and the latter, divided by x , the denominator of a fraction expressing the length of the subtangent BD, which, in this case, will be $= \frac{-2xxy + 2byy - 3y^3}{3xx - 4xy + 2bx - bb}$.

SUBTENSE, in geometry, the same with chord. See CHORD.

SUBTERRANEAN, or SUBTERRANEAN, something under-ground.

The word is formed from the Latin, *sub*, under, and *terra*, the earth.

SUBTILE, in physics, intimates a thing exceedingly small, fine, and delicate; such as the animal spirits, the effluvia of odorous bodies, &c. are supposed to be.

SUBTRACTION, or SUBSTRACTION, in arithmetic, is the rule by which one number is deducted from, or taken out of, another, that so the remainder, difference or excess, may be known.

The word is Latin, *substractio*, and is derived from *sub* and *traho*, to draw.

Thus, 6 taken out of 9, there remains 3. This 3 is also the difference betwixt 6 and 9, or it is the excess of 9 above 6.

Therefore the number or sum out of which subtraction is required, must be greater, or at least equal to the subtrahend, or number to be subtracted.

Note. This rule is the converse or direct contrary to addition.

And here the same caution that was given in addition of placing figures directly under those of the same value, viz. units under units, tens under tens, and hundreds under hundreds, &c. must be carefully observed; also, underneath the lowest rank there must be drawn a line, to separate the given numbers from their difference, when it is found.

Then, having placed the lesser number under the greater, the operation may be thus performed.

Rule. Begin at the right-hand figure or place of units, as in addition, and subtract the lower figure from the figure that stands over it, setting down the difference underneath the same; if the two figures chance to be equal, set down a cypher. But, if the upper figure be less than the lower, then you must add 10 to the upper figure more than it is, and from that sum subtract the lower figure, setting down the remainder, as before directed. Now, because the 10, thus added, was supposed to be borrowed from the next superior place, viz. of tens, in the upper figures, therefore you must call the next lower figure one more than it really is, and then proceed to subtract in that place as in the former; and so gradually on from one row of figures to another, until all be done.

Examp. 1. Let it be required to find the difference between 6785 and 4572. — That is, let 4572 be subtracted from 6785. These numbers, being placed down as before directed, will stand

$$\begin{array}{r} 6785 \\ - 4572 \\ \hline 2213 \end{array}$$

Beginning at the place of units, take 2 from 5, and there will remain 3, which must be set down underneath its own place; and then proceed to the place of tens, taking 7 from 8, and there will remain 1, to be set down underneath its own place; again, at the place of hundreds, take 5 from 7, and there remains 2, which is set down in its place; lastly, take 4 from 6, and there remains 2, which being set underneath its own place, the work is finished, and the difference so found will be $2213 = 6785 - 4572$, as was required.

Example 2. The difference between 5849 and 7946 is required?

$$\begin{array}{r} 7946 \\ - 5849 \\ \hline 2097 \end{array}$$

Having placed the figures as above, begin at the units place, and say 9 from 6 cannot be, but from 16 (as above directed) and there remains 7 to be set down under its own place; next proceed to the place of tens, and add 1 to the lower figure, which will pay the 10 you added to the former 6, to make it 16. This being done, the lower figure in the place of tens, which is 4, will be 5, which you must subtract from the figure above, saying 5 from 4 cannot be, but from 14 (by adding 10 to it) and there will remain 9, which must be put down in its place; then adding 1 to the next lower figure 8, in the place of hundreds, for the last 10 added, it will be 9, which taken or subtracted from the figure above it, which is 9, and there remains 0, which must be set down in its place; and proceed to the last, saying 5 from 7 and there remains 2, which being set down under its own place, all is done, and the difference required will be $2097 = 7946 - 5849$.

SUBTRACTION of divers Denominations, as of money, &c. — Begin with the lowest or least denomination, and subtract the figure or figures in that place, from the figure or figures that stand over them of the same denomination, setting down the remainder; but if the lower

figure be greater than that above it, you must increase the upper figure by adding to it one of the next superior denomination, and from that sum subtract, and then proceed to the next superior denomination, and add one to the lower figure for what you borrowed, as in whole numbers.

$$\begin{array}{r} \text{From } 38698 \\ \text{Take } 17346 \\ \hline 21352 \end{array} \quad \begin{array}{r} \text{From } 569106 \\ \text{Sub. } 389158 \\ \hline 1791410 \end{array}$$

The first of these examples is self-evident; in the second example, beginning at the place of pence, being the least denomination, I am to take 8 from 6, but as that cannot be done, I must, according to the rule, borrow one of the next denomination, viz. 1 s. and add it to the 6 d. which makes it 18 d. then I take 8 d. from it, and there remains 10 d. to be set down underneath the place of pence; that done, I proceed to the place of shillings, carrying 1 to the lower figure 15 for what I borrowed, which makes it 16, which from ten cannot be got; but from 30, by borrowing one of the next denomination, viz. 1 l. and there remains 14, which having set down in its proper place, I proceed to the place of pounds, where carrying the 1 I borrowed to 9 makes 10 from 19, and there remains 9; and so on as in whole numbers till all be finished.

SUBTRACTION of Algebra, is performed by the following general rule. — Change the signs of the quantity to be subtracted into their contrary signs, and then add it, so changed, to the quantity from which it was to be subtracted, and the sum arising by this addition is the remainder. For to subtract any quantity positive, or negative, is the same as to add the opposite kind.

$$\begin{array}{r} \text{Example. From } +5a \\ \text{Subtract } +3a \\ \hline \text{Remainder } 5a - 3a, \text{ or } 2a \end{array} \quad \begin{array}{r} 8a - 7b \\ 3a + 4b \\ \hline 5a - 11b \end{array}$$

$$\begin{array}{r} \text{From } 2a - 3x + 5y - 6 \\ \text{Subtract } 6a + 4x + 5y + 4 \\ \hline \text{Rem. } -4a - 7x - 10 \end{array}$$

It is evident, that to subtract or take away a decrement is the same as adding an equal increment. If we take away $-b$ from $a - b$, there remains a ; and if we add $+b$ to $a - b$, the sum is likewise a . In general, the subtraction of a negative quantity is equivalent to adding its positive value.

SUBTRIPLE Ratio, is when one number or quantity is contained in another three times.

Thus, 2 is said to be the subtriple of 6, and 6 the triple of 2.

SUBULATED, something in the shape of an awl: thus, a subulated leaf is one of an oblong and narrow figure, broadest at the base, and thence gradually decreasing, till it terminates in a point.

SUCCEDANEUM, in pharmacy, a remedy substituted in the place of another first prescribed, when the ingredients are wanting necessary for the composition of that other.

The word is formed from the Latin, *succedo*, to succeed, or come after.

SUCCESSION, *Successio*, in philosophy, an idea which we get by reflecting on that train of ideas constantly following one another in our minds, when awake. See IDEA.

SUCCESSION, in law, implies a right to the whole effects left by a defunct.

SUCCULA, in mechanics, a bare axis, or cylinder, with flaves to it round, but without any tympanum or peritrochium.

SUCKERS, in gardening, the same with off-sets. See OFF SETS.

SUCTION, *Suctio*, the act of sucking or drawing up a fluid, the air, water, milk, or the like, by means of the mouth and lungs.

There are many effects vulgarly attributed to suction, which, in reality, have very different causes. As when

any one sucks water, or any other liquor, up thro' a pipe, it is commonly thought, that by that action the person draws the air up into his mouth, and that the water, which is contiguous to it, follows it by a kind of attraction, as if the air and water hung together; and others fancy, that the air moves into the mouth of the sucker, and the water moves up after the air, to prevent a vacuum, which, they say, nature abhors: whereas the true cause of this phenomenon is only, that the air and atmosphere presses, with its whole weight, uniformly on the surface of the liquor in the vessel; and, consequently, prevents any one part of the water to rise higher than the other there: and if a pipe be put in, of any tolerable large bore, and be open at both ends, the water will rise within the pipe to the same height as without, and indeed, a little higher, because the pressure of the air within the pipe is a little taken off by bearing against the sides of the pipe. Now when any one applies his mouth to the upper end of the pipe, and sucks, his lips so strongly inclose the pipe, that no air can get between them and it; and by the voluntary motion of the spirits in the muscles, the cavity of his thorax, or breast, is opened and enlarged; by which means the air, included there, hath now a much larger space to dilate itself in, and, consequently, cannot press so strongly against the upper end of the pipe, as it did before the cavity of the thorax was so enlarged, and when the weight of the whole atmosphere kept its spring bent. And that weight or pressure being now taken off by the lips of the man that sucks, the equilibrium is destroyed, the air gravitates on the surface of the water, but cannot do so on the upper orifice of the pipe, because the juncture of the lips takes it off; and the spring of the air included in the thorax, being weakened by the dilation of its cavity, it cannot press so hard against the upper orifice of the pipe, as the water will do against the lower, and, consequently, the water must be forced up into the pipe. It is much the same thing in the suction of a common pump: the sucker being tight, takes off entirely the pressure of the atmosphere on the surface of the water within the barrel of the pump; and, consequently, the atmosphere, by its weight, must force the water up to make the equilibrium.

SUDAMINA, little heat pimples in the skin, like the millet-grains, frequent in youth, especially those of a hot temperament, and that use much exercise.

SUDATORY, a name given by the ancient Romans to their hot or sweating rooms; sometimes, also, called *Laconica*.

SUDOR ANGLICANUS, the sweating-sickness, a disease so called from its appearing first in England, in the year 1483.

It seized different patients in different manners; for in some it first appeared with a pain in the neck, scapula, legs, or arms; whilst others perceived only a kind of warm vapour, or flatulence, running through those parts. And these symptoms were suddenly succeeded by a profuse sweat, which the patient could not account for. The internal parts became first warm, and were soon after seized with an incredible heat, which thence diffused itself to the extremities of the body. An intolerable thirst, restlessness, and indisposition of the heart, liver and stomach, were the next symptoms, which were succeeded by an excessive head-ach, or delirium, in which the patient was very trifling and talkative; and after these, a kind of extenuation of the body, and an irresistible necessity of sleeping.

For preventing this disease, temperance is ordered, and the choice of salutary aliments and drinks. No crude pot-herbs nor sallads are to be used, because they may have received a noxious quality from the air; or, if they are used, they are to be previously washed with warm water.

SUDORIFIC, in medicine, a remedy that causes or promotes sweat.

The word is formed from the Latin *sudor*, sweat, and *facio*, to cause.

SUET, *Sevum*, or *Sebum*, in anatomy, the solid fat found in several animals, as sheep, oxen, &c. but not in the human species.

SUFFITUS, in medicine, the same with fumigation. See **FUMIGATION**.

SUFFOCATION, in medicine, the privation of respiration, or breathing; which is sometimes occasioned by a congestion of blood in the lungs, so as to prevent the ingress of the air.

The fumes of wine, or other strong liquors, when boiling, likewise cause suffocation; as do the fumes of lime, charcoal, antimony, sulphur, vitriol, spirit of nitre, &c.

SUFFOCATION of the Womb, or Matrix, is a disease pretty frequent in women, called also fits of the mother.

In this the patient imagines a malignant vapour rising from the matrix, and so pressing against the lungs and diaphragm, as to prevent the free motion necessary to respiration.

SUFFOCATIVE CATARRH. See the article **CATARRH**.

SUFFRAGAN, an appellation given to simple bishops, with respect to archbishops, on whom they depend, and to whom appeals lie from the bishop's courts.

SUFFRAGE, *Suffragium*, a voice or vote given in an assembly where something is deliberated on, or where a person is elected to an office or benefice.

SUFFUMIGATION, or **FUMIGATION**. See **FUMIGATION**.

SUFFUSION, in medicine, the same with cataract. See **CATARACT**.

SUGAR, *Saccharum*, a very sweet agreeable substance, extracted from a kind of canes, or reeds, growing in great plenty in both the East and West-Indies.

Sugar grows in a long stalk, which is called a cane, full of joints, two, three, four, or five inches asunder, and about six foot high, the spouts and leaves of which rising up so high, as may make it near eight feet in all. The body of the cane is about an inch in diameter, seldom more; the colour of the cane-tops is a pure grass-green; the cane itself is yellowish when ripe: it is covered with a thin skin or bark, somewhat hard on the inside, being of a white spongy substance, full of juice, which the inhabitants of Jamaica suck and eat in great quantities, without injuring their health: nothing is pleasanter than this sap, when the cane is ripe; it is also very nourishing and wholesome, if taken with moderation. Their way of eating it is thus: they cut the skin or rind off, and put the pile or spongy parts into their mouths, when the juice will come out more freely than honey out of the comb: it is not surfeiting, but the cleanest and best sweet in the universe. The nature of this juice is much like to that of apples, but something thicker; it is yellow when the cane is ripe, clean, and without any ill taste or smell, and goes off the palate as sweetly as it came on. Of this juice, sugar, rum, and melasses are made.

The season for planting sugar-canes, is from August to the beginning of December; which do not arrive to maturity, till they have been a year and a quarter, or eighteen months in the ground.

Their manner of growing is in sprouts, three, four, or five from one root. They are not all of a size, either in bigness or length, according to the goodness of the soil, and the seasons. Some canes will not rise above three feet high, and others six, and the flags or cane tops of them exceed that stalk and all, and sometimes are under six. These cane-tops make very good food for horses and black cattle; but the solid canes are carried to the mill, for the uses we shall mention hereafter.

The manner of planting them, is by digging long trenches in the earth, about six inches deep, and as many broad, and laying a double row of canes along in the trench one by another, from one end of the trench to the other; then the earth is thrown in, and another trench dug, and so another, at about two feet distance, till all the land is planted, by laying the canes along: thus they produce the greater number of sprouts; for this way, a branch shoots out of every joint of the cane, whereas the first planters used to thrust a piece of cane perpendicularly into a hole, at certain distances, which yielded

yielded no shoot but from the top; and having three or four sprouts, whose whole weight depended on one root, when they grew tall and heavy, the stems loosened the roots, and so they rotted, and became good for nothing. By this new way of planting the root is secured, and the produce increased. They come up in a little while after they are planted, and in about twelve weeks they will be two feet high.

The next care of the planter, is to keep the canes well weeded, weeds being very apt to grow among them; and formerly the withes in particular, a creeper that runs along the ground, and fastens to the canes, by which they hinder their growth.

The roots must also be examined, to see if any have failed, that they may be supplied in time with others, lest the ground should yield something hurtful to the plant.

The practice now is to dung the canes, which is done either when they are planted, or when they come up, and are two feet high; and this is the greatest trouble and expence the planter is at; for if it was not for this dunging, a third part of the negroes would do his business.

When the canes are ripe, which is known by their colour, they are cut up with a bill, or other tool, by one at a time; for if they are too big to be moved with a scythe, or cut with a hook. As they cut them, they trim them, chop off the top, and cut or strip off the leaves or flags on the sides, which are saved for the uses we have already observed.

The canes thus cut, are bundled up in faggots, and tied up with the tops of the canes; they are then carried to the mill by affinegoes, in carts, or drawn by horses.

The mills that are mostly used at Jamaica, are cattle mills; but lately, some substantial planters have one or two wind-mills, and some three. The late president Ascoug erected one at his plantation to windward, which is very curious.

The cattle-mills, water-mills, and wind-mills, are made after the same manner as those in England, and they grind the canes thus in the cattle-mills: the horses and cattle being put to their tackle, go about, and turn by sweeps the middle roller; which being cogg'd at the upper end, turn the others about. They all three turn upon the same centers, which are of brass and steel, going so easily of themselves, that a man taking hold of one of the sweeps with his hands, may turn all the rollers about; but when the canes are put in between the rollers, it is a good draught for five oxen or horses. A negro-woman puts in the canes on one side, and the rollers draw them through on the other, where another negro-woman stands, receives them, and returns them back on the other side of the middle roller, which draws the other way.

This operation presses out the juice, and the English do no more to the canes: but the Spaniards have a press to squeeze out the remainder of the liquor, after both the former grindings. Their works are small, and so are willing to make the most of them.

Mr. Ligon, from whom some part of this account of the cattle-mill is taken, speaks more largely of it; but what we have said, may give the reader some idea of the machine. The rollers are of wood, cas'd with iron, and they press out the juice so thoroughly, that there is no occasion of a press to squeeze them; for in an hour's time the sun dries the canes so much, that they are fit to burn. Under the rollers there is a hollow place, into which all the juice that runs from the canes is received, and by pipes of lead, or leaden gutters covered close over, conveyed into a cistern.

When sugar was first cultivated in this island, one acre of canes yielded more than now, for four, five, six, or seven years together, without any further planting or dunging; the same root would shoot forth new branches, and those be fuller of sap than the canes are at this time; when the sugar being of so great a substance, and containing such a quantity of rich juices, and the planters pressing it so often with the same plant, and never letting it lie still, the soil is so impoverished, that they are now obliged to dung and plant every year; insomuch that a

hundred acres of cane require almost double the number of hands they did formerly, while the land retained its natural vigour, which also then, did not only bring forth certain crops, but fewer weeds too, the weeds having been increased by frequent dunging.

Most of the sugar islands, Jamaica especially, have a kind of white chalky gravel, called marle, two or three feet deep, which of itself is of so hot a temper, and is increased so much by dunging, that their crops in all dry seasons are sure to fail; and, on the other hand, in a wet year, the canes grow rank, and never come to maturity.

When the liquor is in the cistern, it must not remain there above one day, lest it grow sour: from thence it is conveyed through a gutter, fixed to the walls of the boiling house, to the clarifying copper or boiler; and there boiled, till all the filth or gross matter rising in the top is skimmed off. This is the largest copper in the boiling-house; and as the liquor is refined, it is taken out of the copper, and carried into the second, and so into a third, fourth, fifth, sixth, and seventh. The least is called the tach, where it boils longest. It is continually kept stirring till it comes to a consistency; and yet all this boiling would reduce it only to a thick clammy substance, without turning it to a grain, were it not for the temper that is thrown into it. This ley or temper was many years ago made of the ashes of withes, which in the field was so destructive to the cane; the temper now used, is made of lime infused in common water. When the sugar begins to rise up with a turbulent ungovernable fury, occasioned by the fermentation of the liquor of the lime-water, and the vehement heat of the fire, to prevent its running over, they throw in a small piece of tallow no bigger than a nut. This presently makes it fall.

From the boiler the liquor is emptied into a cooler, where it remains till it is fit to be potted. These pots are wide at top, and taper downwards, where a hole is left for the molasses to drain. The hot liquor would run out, but the pots are stop'd with a twig till they are set upon the dripps. In refining the sugar, the first degree of pureness is effected by permitting the molasses to drain away through the hole at the bottom of the sugar-pots, they being all the time open at the top. The second degree is procured by dissolving it in lime-water, clarifying it, and boiling it down to a due consistence: after which it is poured again into the sugar-pots, having their lower holes stop'd with plugs. When the sugar has concreted into a mass, the liquid part is drained off by the aperture; and some fine clay, softened with water into a paste or batter, is spread upon the upper broad surface: the moisture of the clay slowly imbibed by, and percolating through, the sugar, carries down with it great part of the remains of the treacly matter.

The clayed sugar imported from America, is by our refiners dissolved in water, the solution clarified with whites of eggs, and after due inspissation, poured as before into conical moulds, where as soon as the sugar has concreted, and the fluid part is drained off by the aperture at the bottom, the surface of the loaf is again covered with moist clay. The sugar, thus refined, becomes, by a repetition of the process, the double refined sugar of the shops.

Sugar dissolves, by the assistance of heat, in rectified spirit; but greatest part of it separates again in the cold, and concretes into a crystalline form: on this foundation saccharine concretions are obtained from saturated spirituous tinctures of several of the sweet plants of our own growth; the saccharine part separating when the tincture is set in the cold, while the resinous or other matter extracted from the plant, remains dissolved in the spirit. Solutions of sugar mingle uniformly with those of other saline substances, whether acid, alkaline, or neutral; and make no visible alteration in the infusions of the coloured flowers of vegetables, or other liquors, in which acids or alcalies produce a change of colour or a precipitation. This sweet saline substance appears on all trials completely neutral; and unites with most kinds of humid bodies, without altering their native qualities: it serves as an intermedium for uniting together some bodies

dies naturally repugnant, as distilled oils and water. On the same principle it impedes the coagulation of milk, and the separation of its butyraceous part.

Sugar, in consequence of this property, is supposed to unite the unctuous part of the food with the animal juices. Hence some have concluded, that it increases corpulence or fatness; others, that it has a contrary effect, by preventing the separation of the oily matter, which forms fat, from the blood; and others, that it renders the juices thicker and more sluggish, retards the circulation, obstructs the natural secretions, and thus occasions or aggravates scorbutic, cachectic, hypochondriacal, and other disorders. General experience, however, has not shewn, that sugar produces any of these effects in any remarkable degree: its moderate use appears to be innocent; and perhaps, of all that have yet been discovered, it is the most universally innocent and inoffensive, as well as the most simple, sweet.

Sugar preserves both animal and vegetable substances from putrefaction, and appears to possess this power in a higher degree than the common alimentary salt; animal flesh having been preserved by it untainted for upwards of three years. From this it has been sometimes applied externally as a balsamic and antiseptic. The impure brown sugars, by virtue of their oily or treacly matter, prove emollient and gently laxative. The uses of sugar in medicinal compositions, whether for their preservation, for procuring the intended form and consistence, or for reconciling to the stomach and palate substances of themselves disgusting, are too obvious to require being enlarged on.

Sugar was known to the ancients; Dioscorides and Galen called it *saccharum*, and Theophrastus *mel* in *arundinibus*, honey in reeds. Arrian also calls it *mel arundineum*, and Ægineta *sal Indicus*, Indian salt. Notwithstanding, however, that the ancients were all acquainted with sugar, they did not bring it into common use as we do. All their writers, however, mention it as a thing known. Strabo says, that Indian honey, as he calls it, was produced without bees. Lucan speaks of the honey-juice of reeds; and Varro tells us, that a sweet juice was expressed from the Indian reeds, and was equal to honey. Seneca tells us of honey found in reeds, in India, and is in some doubt whether it was a honeydew, as they supposed manna to be, or whether it was the genuine product of those reeds. The Greeks indifferently called the sugar of those times by the names of honey, salt, and sugar.

Dioscorides makes it a kind of honey, and says, that, besides the common honey, there was another sort called *saccharum*, which was found in reeds, in Arabia and the Indies, and was like a salt, hard and brittle under the teeth. Pliny also agrees that there were sugar-canes in Arabia, which produced sugar like those of the Indies, but that it was inferior to that of India.

We find by all their accounts, that they knew the sweet juice of these reeds, and that they also sometimes, had sent over to them concremented granules of real sugar, which had exsuded from the reeds, and dried in the sun to a hardness; these were the pieces of sugar which Dioscorides mentions, as crackling under the teeth. And others tell us they were of the size of a pea, or at the most of a horse-bean. It is plain, however, that they knew nothing of the art of making sugar by boiling the juice.

As plain as it appears that the ancients not only knew sugar, but knew also it was produced from reeds, it does not yet appear, however, whether they knew the very species of reed which we now cultivate, and call the sugar-cane, or not. It is very certain, that there are other plants which may be called canes and reeds, and which produce sugar, in the Indies, as well as this: the bambu-cane, in particular, is remarkable, not only for producing sugar, but for having it exsude and concrete in granules on its surface, though in no great quantity. The Indians call this *sacchar manna*, but they do not boil its juice.

Salmasius, from Varro and some other of the ancients, talking of the Indian sugar-cane, as growing to the height of a moderate tree, seems positive, that the bambu was the only kind they knew; but though it may ap-

pear evidently enough from this, that they knew the bambu or bambu, it does not appear hence that they did not also know the common sugar reed of our times; which, indeed, it seems, in some measure, proved that they did, by Lucan's calling it the *tenera arundo*, a term no way applicable to the bambu.

The native sugar, or the concreted juice of the sugar-cane produced by mere exsudation, and hardened on its bark, was more frequent in the ancient times than now, because older and larger reeds are more disposed to produce it. It was also more carefully collected, when there was no other to be had; but now that the canes are cut down at a year's growth, and the sugar procured in such infinitely greater quantities by boiling, it is not wonderful that little of the native sugar is produced, or what there is, is but little regarded.

The Arabians all mention three kinds of sugar: 1. *Saccharum arundineum* of Avicenna, which was found naturally exsuded on the sugar-canes now propagated. 2. The *tabaxir* of the same author, which was the native sugar of the bambu: it appears probable, that all these authors understood, by the same name, a coarse kind of sugar produced by art, for they speak sometimes of *tabaxir* resembling ashes, and imagined it to be the ashes of the sugar-canes. 3. The *sacchar alhusar*; or *alhasht*. This they also called manna. It differed from the common sugar in many respects; it had little sweetness, but much of a bitterish taste. It exsuded from the plant they call *alhusa*, in the same manner as their manna did from the *alhagi*; and they, therefore, called it manna. This sugar is not now known in Europe, but in Egypt and Arabia they are well acquainted with it. The plant it exsudes from is the *beid-el-ossar* of Prosper Alpinus. The sugar produced by this plant was, indeed, probably, very different from that of the sugar-cane; this being of the *apocynum* or dog-bane kind, and its juice so acrid, as to be used as a depilatory.

In some parts of North America, particularly in Canada, a kind of sugar is prepared from the juice which issues upon wounding or boring certain species of the maple-tree, one of which is named from hence the sugar maple; as also from the wild or black birch, the honeylocust, and the hickory. The maple is most commonly made use of for this purpose, as being the richest, and as best enduring the long and severe winters of that climate. The juice is boiled down, without any addition, to a thick consistence, then taken off from the fire, kept stirring till its heat is abated, and set in a cold place; where the sugar quickly concretes into grains, resembling common brown sugar.

The trees are topped early in the spring about the time that the snow begins to melt: it is observable, that when the weather begins to grow warm, they bleed no more; and that after the bleeding has stopt, they begin to run again upon covering the roots with snow. The more severe the winter has been, the juice is found to be richer and in greater quantity. The trees which grow on hills, or high lands, yield a richer juice than those which are produced in low countries; and the middle-aged than the young or the old.

Mr. Kalm informs us, in the Swedish Transactions for the year 1751, that one tree, if the summer does not come on hastily, will yield about forty-two gallons of juice, English wine measure, and that the quantity which issues in one day is from three to six gallons: that eleven gallons of juice of middling quality give a pound of sugar, and that sometimes a pound has been gained from three gallons and a half: that two persons can in one spring prepare commodiously two hundred pounds. He observes that this sugar is weaker than that from the sugar-cane, but that for some purposes it answers better, as for chocolate and preserves. It is likewise esteemed more medicinal: considerable quantities are brought annually into Europe, particularly France, and there employed in disorders of the breast. It is reckoned that a pound of common sugar goes as far in sweetening as two pounds of maple sugar.

The large maple, commonly called *sycamore-tree*, bleeds also in Europe a sweet juice, from which an actual sugar has been prepared. In the Transactions above-mentioned, for the year 1754, there is an account of some

some experiments made in this view upon the Swedish maple. Eight trees, none of them under thirty years, bled, in four days, fourteen gallons of juice, which inspissated gave two pounds and a half of brown sugar. Another time, the same eight trees bled, in three days, ten gallons and a half, which yielded one pound four ounces of sugar, with half a pound of syrup. It is the saccharine juice of the maple-tree, which, exuding upon the leaves, renders them so apt to be preyed upon by insects.

The common birch bleeds also a large quantity of a sweetish juice, which yields on being inspissated a sweet saline concrete, not however perfectly of the saccharine kind, but seeming to approach more to the nature of manna.

There are sundry other vegetables, raised in our own country, which afford saccharine concretes; as beet roots, skirrets, parsnips, potatoes, celery, red cabbage-stalks, the young shoots of Indian-wheat, &c. The sugar is most readily obtained from these, by making a tincture of the subject in rectified spirit of wine; which when saturated by heat will deposite the sugar upon standing in the cold.

SUGAR-MILL, a machine for bruising the sugar canes, in order to extract their juice, for making sugar.

We have already mentioned, in the preceding article, the principles on which the sugar-mill is constructed: but in order to convey a more adequate idea of these machines, we have given perspective views of two on plate CXXIV. one turned by horses, the other by water.

Fig. 1. is a sugar-mill worked by horses, or other animals. A, A, the frame of wood made very strong. B, B, the basin of the mill, made out of a large block of wood, the upper surface of which is hollowed, and lined with lead. C, C, C, three rollers, revolving on an iron axis, their lower and upper extremities being formed into pivots, which move in gudgeons. D, D, D, D, apertures for changing, or repairing the pivots or gudgeons. E, E, two large apertures, for locking or fastening the wedges which support the pivots, and consequently keep the rollers in their proper position. F, F, apertures of the same kind, for fastening the wedges of the upper pivots. G, G, toothed wheels fixed to the upper ends of the rollers, by which they are turned contrary ways. H, the axis, or arbor of the middle roller extended. I, the collar, in which the point of that extended axis turns. K, K, arms of the mill, by which the moving force is applied. L, L, pieces of timber, for supporting the collar. M, a pipe, or gutter, for conveying the juice pressed out of the cane by the mill to the boiling house.

Fig. 2. A sugar-mill turned by a fall of water. A, A, the frame of the mill, made very strong. B, the basin of the mill lined with lead for receiving the juice of the sugar-canes, as in the preceding figure. C, C, C, the three rollers, described in the first figure. D, the vertical arbor of the middle roller, which is turned by a cog-wheel F; its pivot moving in a gudgeon supported by the pieces E, E. F, the cog-wheel, which turns the middle roller, and consequently the other two rollers the contrary way. G, another cog-wheel which acts as a lantern, and moves the cog-wheel F. H, the axis or shaft of the great-wheel. I, the buckets of the large wheel, filled by the fall of water from the trough K. L, a small gutter of wood, which carries the juice of the sugar from the mill to the boiling-house. M, the negro who puts the sugar canes into the mill. N, the sugar canes. O, a pulley for raising the arbor, when the lower pivots, &c. want repairing.

SUGAR-CANDY, *Saccharum Candum*, or *CrySTALLinum*, is sugar depurated and crystallised.

This is better made of earthed sugar, than refined sugar, in regard the former is sweeter.

The sugar to be used herein is first dissolved in a weak lime-water, then clarified, scummed, strained through a cloth, and boiled, and put in forms or moulds that are traversed with little rods, to retain the sugar, as it crystallises. These forms are suspended in a hot stove, with a pot underneath, to receive the syrup that drops out at the hole in the bottom, which is half stopped, that the filtration may be the gentler. When the

forms are full, the stove is shut up, and the fire made very vehement.

Upon this the sugar fastens to the sticks that cross the forms, and there hangs in little splinters of crystal. When the sugar is quite dry, the forms are broke and the sugar taken out, candied. Red sugar-candy they make, by casting into the vessel, where the sugar is boiling, a little juice of the Indian fig; and, if it is desired to have it perfumed, they cast a drop of some essence in, when the sugar is putting into the forms.

This method of making sugar-candy is that of F. Labat, practised in the Caribbees: the method in Europe, described by Pomet, is somewhat different.

White SUGAR-CANDY, they make of white refined sugar, boiled with water into a thick syrup, in a large pan. It is candied in a stove, whither it is carried, inclosed in brass peels, crossed with little rods, about which the crystals fasten, as they are formed.

The fire of the stove is kept equable for fifteen days; after which the sugar is taken out of the peels to be dried. Red or brown sugar-candy is made like the white, except that they only use brown sugars and earthen pots.

Barley SUGAR, *Saccharum Hordeatum*, is a sugar boiled till it be brittle, and then cast on a stone anointed with oil of sweet almonds, and formed into twisted sticks, about the length of the hand, and the thickness of a finger.

It should be boiled up with a decoction of barley, whence it takes its name; but in lieu thereof they now generally use common water, to make the sugar the finer. — To give it the brighter amber colour, they sometimes cast saffron into it. — It is found very good for the cure of colds and rheums.

SUGAR-SPIRIT, a name given by our distillers to a spirit made in England, Holland, and other places, from the washings, scummings, dross, and waste of a sugar-baker's refining-house. The manner of preparing it is the same with that used for the malt and melasses spirits. The refuse of the sugar is fermented with water in the usual manner, then distilled into what is called low wines, and afterwards rectified, without an addition, into proof spirit.

When the operation is well performed, and no foul, foetid, or foreign matter, has got in among the wash, this is a tolerably clean spirit. We usually make it such, but in Holland it is usually made very nauseous and disagreeable; though capable, by an easy rectification familiar with us, though not much known abroad, of being brought to a fine and clean spirit. With us this sugar spirit is used to mix with and adulterate brandy, rum, and arrac, which will receive a large dose of it without its being at all discoverable; but the Dutch who have it very coarse, can only adulterate rum with it, and even that will bear but a small proportion, without being betrayed by its nauseousness.

This sugar spirit reduced to alcohol makes one of the purest spirits we are acquainted with, much superior to that of melasses, and much more to that of malt. *Shaw's Essay on Dist.*

SUGILLATION, in medicine, an extravasation of blood in the coats of the eye, which at first appears of a reddish colour, and afterwards livid or black. If the disorder is great, bleeding and purging are proper, as are discutients. The following cataplasm is said to be very good: Take of comfrey-root, six ounces; of Solomon's seal, two ounces; of elder-flowers, one ounce and a half; of bean-flour, one ounce; let all these be boiled in a sufficient quantity of spring-water. The decoction may be used as a fucus, and the ingredients for a cataplasm.

SUIT, in law, is used in different senses; as, 1. For an action, whether personal or real. 2. Suit of court, or suit-service, which is an attendance the tenant owes to his lord's court. 3. Suit covenant, where a person has covenanted to do service in the court of the lord. 4. Suit custom, which is where one and his ancestors have owed suit time out of mind. 5. It is used for a petition to the king, or any person of dignity: where a lord distrains his tenant for suit, and none is due; in this case, the party may have an attachment against him to appear in the king's court. 6. Suit of the king's

peace, is an action brought against a person for breach of the king's peace; as in the case of treasons, felonies, or trespasses.

SULPHUR, in natural history, a mineral substance, fusible and inflammable by fire, and not dissoluble or miscible in water. The name sulphur has been applied by some to the inflammable principle of bodies; by others, to all inflammable mixts, or substances participating of this principle; and the alchemists speak also of a sulphur that does not burn. Vegetable oils and resins, animal fats, mineral bitumens, are by some called sulphurs; and by some sulphur itself is referred to the bitumens. This confusion has given rise to numerous errors and absurdities: how widely different is true sulphur, in all its properties, from bitumens, or oils, or any other kind of inflammable body! If every thing that burns was to be called sulphur, we might with equal propriety call every thing that is liquid by the name of water, or of spirit of wine, or vinegar, or oil, or any other particular liquor. Experiment has fully evinced, that sulphur is no other than the concentrated vitriolic acid combined with a small proportion of the phlogistic or inflammable principle; and to this combination alone, which is always one and the same, excepting for adventitious admixtures, the more judicious chemists have wholly confined the name.

Sulphur is a solid brittle concrete, of a yellow colour inclining a little to greenish, in some degree glossy. Held in the warm hand, it crackles, or bursts: and leaves on the hand a particular kind of smell. It is nearly twice as heavy as an equal bulk of water.

It melts in a small degree of heat into a red pellucid fluid, and on cooling concretes again into its original appearance. Some have endeavoured to purify sulphur from the drossy matters which are often mixed with it, by melting and pouring it into spirit of wine: others have melted it with wax, and poured the fluid mixture into water when the sulphur subsides, and the wax rises to the surface, carrying up with it a part of the impurities. With regard to spirit of wine, it can have no effect in separating foreign matters from the sulphur, though it seems in some measure to heighten the yellow colour. Wax on the other hand renders it greener, and if the fusion is several times repeated, changes it quite blackish.

Sulphur kept in fusion, gradually exhales: if the air is excluded, it sublimes into the upper part of the vessel, without undergoing any other alteration, than being reduced into the form of powder or flowers. This property affords a method of purifying it effectually from earthy, stony, or other fixed matters; and at the same time of reducing it into a finer powder than can easily be obtained by trituration. Where only a small quantity of flowers of sulphur is wanted, the sublimation may be performed in a jar, with aludels closely luted upon it, and a blind-head at top. In England, they are prepared by particular persons in the way of trade: the subliming vessel is an iron pot, so large as to hold two or three hundred weight or more of sulphur, about a fourth of its capacity remaining empty: the recipient is an arched room built above the pot, and communicating with it at one side by an aperture of six or eight or more inches in diameter. The room is lined with glazed tiles; and furnished with a door, by which a man may creep in, when the operation is finished, to sweep out the flowers. In the middle of the door is a small hole, which is opened occasionally during the sublimation, for examining whether the flowers continue or have ceased to arise.

In open vessels, sulphur readily takes fire from the contact of ignited bodies, and if kept in fusion, burns entirely away, with a blue flame, and a diffusive suffocating fume. This fume is no other than the vitriolic acid volatilized by the flame: a considerable quantity of it may be detained, and condensed into a liquid form, by placing over the burning sulphur capacious glass vessels, replete with aqueous vapours: the larger the receivers, and the less communication the flame has with the external air, the more of the fumes will be preserved.

The common apparatus for this purpose consists of a little earthen dish, for burning the sulphur in; a glass

bell, suspended over the flame; and a broad glass or earthen vessel, which supports the dish with the sulphur, and receives the acid liquor as it drops from the sides of the bell. Many variations have been made in this apparatus, with a view to detain the fumes more effectually. Instead of the bell, from which the acid has received the name of spiritus sulphuris per campanam, some have employed a glass differing from that shape in having a rim turned in at the bottom, and a tube at the top, to which a receiver is fitted as an enlargement of the capacity of the vessel; others a retort, with its bottom cut out, and a glass body or tubulated receiver applied to its neck; others a receiver, with a hole in its bottom for admitting the flame; others a glass body, with some water in its bottom, holes in the sides, a crucible with burning sulphur placed in the water, and another body inverted on the mouth: some have suspended the burning sulphur in a wooden cask half full of water, and afterwards rectified the liquor. The grand difficulty is, that sulphur will not burn without a draught of air, and the acid fumes are so volatile that far the greatest part of them is carried off by the air. Some direct a little nitre to be mixed with the sulphur, to promote its burning; but though nitre is undoubtedly of advantage in that respect, it is injurious in another; rendering the product impure, by giving out its own acid along with that of the sulphur. Many other contrivances have been made, but none with any commendable success; the same acid being obtainable at a much easier rate from vitriol, than by any methods of procedure to which sulphur has hitherto been submitted. The best way hitherto discovered of collecting the acid spirit of sulphur in a volatile state, is that given by Stahl: the sulphur is made to burn slowly by means of a wick, a number of aludels set over it, and a cloth moistened with strong alkaline ley placed in each aludel: as soon as any of the cloths become dry, a moist one is put in its room. The alkaline salt which the cloths were impregnated with, imbibes the acid fumes, and is thus converted into a neutral salt, which is easily rubbed out. It is the volatile vitriolic acid that this salt contains; and hence, upon adding to it common oil of vitriol, in a tubulated retort, the volatile spirit distils, leaving the alkali combined with the more powerful fixed acid superadded. The volatile however, as well as the fixed acid is still more commodiously and advantageously obtainable from vitriol itself.

It was formerly supposed, that the acid spirits of vitriol and sulphur were really different from one another, and hence they were received in the shops as two distinct acids: their identity is evident from hence; that the spirit obtained from common sulphur, united with metals, forms a true vitriol: and the spirit extracted from common vitriol forms, with inflammable substances, a perfect sulphur, not distinguishable on any trial from pure mineral brimstone.

Sulphur does not dissolve in water, in spirit of wine, or in acid liquors: the vitriolic acid, nevertheless, extracts a part of the acid of the sulphur, so as to gain a considerable increase of its own acidity. Fixed alkaline salts, injected upon half their weight or less of melted sulphur, readily unite with it into a red or liver coloured mass, called *hepar sulphuris*, which deliquesces in the air, dissolves in water, and gives a golden tincture to spirit of wine: the watery solution, kept for some time, generally deposits a black powder: sulphur is dissolved also by boiling in fixed alkaline lixivia, or in lime water. The addition of any acid to these solutions, renders them milky, and precipitates the sulphur in form of a white powder called *lac sulphuris*: during the precipitation, an extremely fetid vapour arises, which blackens metalline utensils, particularly silver ones, at a considerable distance.

If the mixture of sulphur and fixed alkaline salt be reduced to powder, kept for some time in a gentle heat, and frequently stirred; the sulphur will be destroyed, or resolved into its constituent parts. The inflammable principle is gradually dissipated, and only the acid of the sulphur remains combined with the alkali. Instead of a red, fetid, alkaline, sulphureous compound, we find now a white, inodorous, neutral salt, the same as if common oil of vitriol had been mixed with the alkali:

From

From this experiment we are enabled to determine the proportions of acid and phlogiston of which sulphur consists; the increase of weight which the alkaline salt acquires being pure concentrated acid. It appears upon careful trial, that in sixteen ounces of sulphur, there are upwards of fifteen ounces and six drams of pure vitriolic acid void of phlegm; the inflammable matter, by which so large a quantity of that most corrosive acid is in all its properties so surprisingly changed, amounting only to about a dram.

Some report that sulphur will dissolve in volatile alkaline spirits, without any intermedium. Boerhaave directs, for this purpose, any strong alkaline spirit to be distilled from flowers of sulphur, and cohobated or drawn over a second time from the residuum; or the mixture to be long kept in a close vessel, and frequently shaken. I tried strong spirits of sal ammoniac, both simple and dulcified, prepared both with alkaline salt and with quick-lime, and a spirit saturated with oil of aniseeds: but none of the five made any solution, or extracted any tincture from the sulphur, either by digestion or distillation.

There are means, however, of procuring a perfect solution of sulphur in volatile spirits; namely, by mixing the sulphur, not with the spirit already prepared, but with crude sal ammoniac; and adding quick-lime to extricate the volatile alkali, which thus will elevate with it in distillation a considerable portion of the sulphur. Beignus takes four parts of sulphur, two of quick-lime, and one of sal-ammoniac. — Hoffmann's proportions, three parts of lime, two of sal ammoniac, and three of sulphur, succeeded better with me. The mixture is to be put into a retort, and distilled by a gradual fire, the juncture of the retort with the receiver being closely luted. The distilled liquor called sulphureous spirit of sal ammoniac, smoking spirit of sulphur, or volatile tincture of sulphur, is extremely volatile and penetrating, emits highly fetid vapours, which blacken silver, and give colour to invisible writings made with saturnine solutions, like the liquor of orpiment. It is employed medicinally in some compositions; internally as a sudorific, and externally as an antipodagric.

Sulphur dissolves in oils, by the assistance of a boiling heat, into a thick, yellowish or reddish fluid, called balsam or oily liver of sulphur. This process should be performed without doors, in large vessels; the matter constantly watched and stirred, and, if it begins to rise up, removed immediately from the fire: otherwise the combustible compound will suddenly run over into the furnace, and may be productive of terrible consequences.

Expressed oils dissolve sulphur far more readily and plentifully than the distilled. The balsams of sulphur with distilled oils, directed in books of pharmacy, are very injudicious preparations; as the oil will scarcely gain any tincture from the sulphur, without a boiling heat; and such a heat will destroy the flavour and peculiar qualities of the oil. If these kinds of preparations are wanted, they may be much more commodiously and advantageously obtained by adding a due proportion of any essential oil to the solution made with expressed ones. Expressed oils will easily take up half their weight of sulphur, and form with it, when grown cold, a thick consistent mass: if this be liquified by a gentle heat, and any essential oil added, they will readily incorporate together. The essential oil of anniseed differs remarkably from all the other distilled oils, in its power of dissolving sulphur; taking up rather more even than the expressed. This oil, digested with the hepar sulphuris, or compositions of sulphur and fixed alkaline salts, readily takes up a large quantity of sulphur from the alkali: other essential oils absorb very little; and expressed ones scarce any at all. It is observable that the balsam of sulphur with oil of turpentine, if saturated with the sulphur whilst hot, concretes on cooling into a curious vegetation resembling a tree.

Sulphur unites in the fire with most metallic bodies, promotes the fusion of the refractory ones iron and copper, renders lead on the other hand almost unfusible, and debases the quality of them all. It changes several into the appearance of their own ores; silver, into a soft leaden coloured substance, resembling the malleable silver

ore; iron and copper into yellowish concretes, like the natural pyritæ; the antimonial regulus into antimony; quicksilver and arsenics into red compounds, the same with the native cinnabar and red arsenic; lead, into a dark-coloured mass, like its common ore; tin into a substance like antimony, a form in which that metal is never found in the earth. Pure sulphur does not act upon gold, but sulphurated alkali or hepar sulphuris unites with gold in fusion as well as with other metals, and renders it dissoluble in water so as to pass through the pores of a filter. The principal use of sulphur is in fire-works, and for making gunpowder. It is likewise employed in some woollen manufactures, in bleaching, for making cinnabar, by the wine-coopers, for sundry æconomical and other like purposes. — It is used medicinally against cutaneous eruptions, and disorders of the lungs: from the virtues attributed to it in this last intention, it has received the name of anima pulmonum.

Sulphur is sometimes found native in the earth, in pure, bright yellow, semitransparent masses; but more commonly in opaque ones, of a greenish, greyish, and other colours, intermixed with various earthy or stony matters: these impure sorts are those commonly understood by the name of sulphur vivum. The native sulphurs are met with chiefly about volcanos in Italy, in some of the German, Hungarian, and Swedish mines. A pale yellow transparent sulphur is brought from Guadeloupe in America; and Monardus mentions a sulphur as transparent as glass, and in colour like gold.

There are likewise reddish, and red sulphurs; of which I have seen some of a semitransparent cinnabarine red: these are never to be employed for medicinal use, as they are rarely free from an admixture of arsenic, and indeed are rather to be looked upon as a native red arsenic or realgar, than as sulphurs: the redder the colour, the more arsenic they generally hold. The greatest quantities of these red arsenical sulphurs are found in the Turkish dominions; and some in the territories of Saltzburg.

Authors mention another sort of native sulphur, which separates from the hot mineral waters, particularly those of Aix-la-chapelle: whether this yellow sediment be a true sulphur or not, I cannot determine, as I have not had an opportunity of examining it.

Sulphur is an ingredient in most kinds of ores, and frequently is the only one by which metallic bodies are debased in the earth into that form. Tin, bismuth, and cobalt are the only ones which have no sulphur in their ores: arsenic and gold are frequently accompanied with it: silver, a good deal more frequently, and lead still more so: of copper, it is a more constant attendant than of any of the foregoing: mercury and regulus of antimony are never found without it. The common ores of iron rarely hold any sulphur: the mineral, however, which contains the largest quantity of sulphur, or from which the sulphur is extracted to the greatest advantage, is a ferrugineous ore, called, from its colour, and from its striking fire with steel, yellow pyrites.

The yellow pyritæ are found most plentifully in some parts of Sweden, and in Saxony, where the principal sulphur works are established. The sulphur is extracted in some places, by distillation in large iron retorts; in others, by eliquation in earthen vessels; the sulphur, as it melts out from the ore, being conveyed along inclined pipes into vessels of cold water. At Goslar, in the Lower Saxony, great quantities of sulphur are collected in the calcination of certain ores in the open air: the ore being stratified with wood, and the wood set on fire, the sulphur melts out in different parts of the pile, and is received in vessels placed underneath, or on cavities made for that purpose in the matter itself when softened by the heat: the rough sulphur obtained by these processes is purified by fusion; which is sometimes twice or thrice repeated: the lighter feculencies, which arise to the surface, are skimmed off; and the fluid sulphur poured from the grosser sediment that falls to the bottom. Most of the sulphur prepared in Germany appears of a fine yellow colour, or inclines but a little to greenish yellow; the Swedish, particularly that which comes from the island Melo, has more of the green, and is not near so fine. The impure sulphur, or dregs remaining after

S U N

the purification, are called sulphur caballinum, as being only fit for horses; but even for such purposes, it is surely more advisable to use pure sulphur, than an unequal and an unknown mineral medley, which may often do more harm than good.

Hoffman and others have presumed, that sulphur exists in the air, and that from this proceed thunder, lightning, and other fiery meteors; the vitriolic acid and inflammable principle, the very ingredients from which art produces sulphur, being unquestionably diffused through the atmosphere. Plausible as this theory may appear, it is liable to considerable objections: art cannot produce sulphur without a degree of fire, which we cannot suppose to have any place in the atmosphere: no sulphur can be generated but with the concentrated acid, and how infinitely, on the other hand, is the aerial acid divided and diluted! Besides, the effects of sulphur and of lightning are in no wise similar. *Neumann's Chemistry.*

SUM, *Summa*, in arithmetic, &c. signifies the quantity that arises from the addition of two or more magnitudes, numbers, or quantities together.

The sum of an equation is, when the absolute number being brought over to the other side with a contrary sign, the whole becomes equal to 0: this Des Cartes calls the sum of the equation proposed.

SUMACH, *Rhus*, in botany, a low tree, or shrub, with oval, pointed, serrated, downy leaves, having each a red rib running along the middle, set in pairs without pedicles, producing clusters of small yellowish or greenish flowers, each of which is followed by a small, red, flattish berry, including a roundish reddish-brown seed. It is a native of the southern parts of Europe, and cultivated in some of our gardens.

The berries of sumach have an acid austere taste: they were formerly used for restraining bilious fluxes, and hemorrhages, and colliquative hectic sweats: some direct an infusion of half an ounce of the berries, and others two or three drams of an extract made from them by water, for a dose. The leaves and young twigs are strong astringents, and have been directed in the same intentions.

SUMMARY, in matters of literature, the same with abridgment.

Summary, however, is often used for a table of contents, placed at the beginning of books, to shew the principal heads treated of therein.

SUMMER, one of the seasons of the year, commencing in these northern regions on the day the sun enters Cancer, and ending when he quits Virgo. Or, more strictly and universally, the summer begins on the day when the sun's meridian distance from the zenith is the least; and ends on the day, when his distance is a mean betwixt the greatest and smallest. The end of summer coincides with the beginning of winter.

SUMMER, in architecture, is a large stone, the first that is laid over columns and pilasters, in beginning to make a cross vault; or it is the stone which, being laid over a piedroit or column, is hollowed to receive the first haunce of a platband.

SUMMER, in carpentry, is a large piece of timber which being supported on two stone piers or posts, serves as a lintel to a door, window, &c.

SUN, *Sol*, in astronomy, the great luminary which enlightens the world, and, by his presence, constitutes day.

Sir Isaac Newton, in his Principia, proves that the matter of the sun to that of Jupiter is nearly as 1100 to 1; and that the distance of that planet from the sun is in the same ratio to the sun's semidiameter.

That the matter of the sun to that of Saturn is as 2360 to 1; and the distance of Saturn from the sun is in a ratio but a little less than that to the sun's semidiameter.

And consequently that the common center of gravity, of the sun and Jupiter, is nearly in the superficies of the sun; of Saturn and the sun, a little within it. And by the same manner of calculation it will be found that the common center of gravity of all the planets cannot be more than the length of the solar diameter distant from the center of the sun. This common center of gravity

S U N

he proves to be at rest; and therefore, though the sun, by reason of the various position of the planets, may be moved every way, yet it cannot recede far from the common center of gravity. And this he thinks ought to be accounted the center of our world. *Book 3. prop. 12.*

By means of the solar spots it hath been discovered, that the sun revolves round his own axis, without moving (considerably) out of his place, in about twenty-five days. And that the axis of this motion is inclined to the ecliptic, in an angle of 87 degrees, 30 min. nearly. *Gregor. Astron.*

The sun's apparent diameter being sensibly shorter in December than in June, as is plain and agreed from observation, the sun must be proportionably nearer to the earth in winter than in summer; in the former of which seasons will be the perihelion, in the latter the aphelion: And this is also confirmed by the earth's moving swifter in December than it doth in June. For since, as Sir Isaac Newton hath demonstrated by a line drawn to the sun, the earth always describes equal areas in equal times, whenever it moves swifter, it must needs be nearer to the sun. And for this reason there are about eight days more from the sun's vernal equinox to the autumnal, than from the autumnal to the vernal.

According to Mr. Cassini, the sun's greatest distance from the earth is 22374, his mean distance 2200, and his least distance 8022 semidiameters of the earth.

And that the sun's diameter is equal to 100 diameters of the earth, and therefore the body of the sun must be 1000000 times greater than that of the earth.

Mr. Azout assures us, that he observed by a very exact method the sun's diameter to be not less than 31 minutes 45 seconds, in his apogee, and not greater than 32 minutes 45 seconds, in his perigee.

The mean apparent diameter of the sun, according to Sir Isaac Newton, is 32 minutes 12 seconds; in his theory of the moon, 32 minutes 15 seconds.

If you divide 360 degrees (i. e. the whole ecliptic) by the quantity of the solar year, it will quote 59 minutes 8 seconds, &c. which therefore is the quantity of the sun's diurnal motion. And, if this 59 minutes 8 seconds be divided by 24, you have the sun's horary motion, which is 2 minutes 28 seconds; and, if you will divide this last by 60, you will have this motion in a minute, &c. And this way are the tables of the sun's mean motion, which you have in the books of astronomical calculation, constructed.

The sun's horizontal parallax Dr. Gregory and Sir Isaac Newton make but 10 seconds.

To find this angle, astronomers have attempted variety of methods, but have as yet found none that will determine it exactly; however, by many repeated observations of Dr. Halley, it is found to be not greater than 12", nor less than 9". Wherefore $10\frac{1}{2}"$ (the mean) has been fixed upon as near the truth. By a transit of Venus over the sun's disk, the same gentleman has shewn how the sun's parallax may be determined to a great nicety, viz. to within a 500th part of the whole. See Phil. Trans. N°. 348, abridged by Jones, Vol IV.

Sir Isaac Newton, in his Optics, gives good reasons to suppose the sun and fixed stars to be great earths vehemently hot; whose heat is conserved by the greatness of their bodies, and the mutual action and re-action between them and the light which they emit; and whose parts are kept from fuming away, not only by their fixity, but also by the vast weight and density of the atmospheres incumbent on them, and every way strongly compressing them, and condensing the vapours and exhalations which arise from them. The light seems to be emitted from the sun and fixed stars (which probably are suns to other systems) much after the manner as iron, when heated to such a degree as to be just going into fusion by the vibrating motion of its parts, emits, with force and violence, copious streams of liquid fire all around. Great bodies must preserve their heat longest, and that, perhaps, in the proportion of their diameters.

Sir Isaac Newton hath made it probable, that the great comet in the year 1680, in its perihelion, would not entirely go off in 50000 years. Whence we may conjecture

ure that if the sun and fixed stars be only collections of dense and solid matter, like the planets, but heated to a very intense degree, they may be many millions of years without losing any considerable part of their heat.

SUN-FLOWER, in botany, a genus of plants, the flower of which is of a radiated kind; its disk is made up of floscules, and its outer edge of semifloscules; these stand upon the embryo seeds, and are separated from one another by little leaves of an imbricated figure, and contained in a scaly husk, or cup; the embryo's finally ripen into seeds furnished with two little leaves. See HELIANTHUS, and HELIANTHEMUM.

There are several different species of this flower, all which are very beautiful in large gardens. They are most of them annual plants, and are to be sown every spring in a bed of good light earth. When the shoots are about three inches high, they must be transplanted into nursery beds, and set at eight inches distant every way; they should remain there till they are a foot high, and then be carefully taken up with a ball of earth at their roots, and planted in large borders, or intermixed in the bosquets of large growing plants; they must be frequently watered till they have taken root, and after that will require no farther care. In July the flowers appear, and stand a considerable time: the largest of these should be left to stand for seed. The birds are very apt to devour this seed, but it should be carefully guarded from them, and the head left on the plant till October, at which time it should be cut off, and hung up to dry in an airy place, and in a month more the seeds will be perfectly hardened.

Several species of this plant also are perennial, and increase greatly by the root. Among these the common smaller flowered one is a very valuable plant in gardens, as it requires no culture, will grow in all soils and situations, and is a very ornamental flower, continuing in bloom from June to October.

SUN-SCORCHED, a term used by our gardeners in some parts of England to express a distemperature of fruit trees, owing to the sun's affecting them forcibly and too suddenly; the consequence of which is the loss and withering of the fruit. Such trees only are subject to this, as are planted in places sheltered from the spring sun, and only open to the summer's; and it may be always cured by proper waterings.

SUNDAY, or the LORD'S-DAY, a solemn festival observed by Christians on the first day of every week, in memory of our Saviour's resurrection.

This is the principal and most noted of the christian festivals, and was observed with great veneration in the ancient church, from the time of the apostles, who themselves are often said to have met on that day for divine service. It is likewise called the sabbath-day, as being substituted in the room of the Jewish sabbath.

The ancients retained the name Sunday, or *dies solis*, in compliance with the ordinary forms of speech, the first day of the week being so called by the Romans, because it was dedicated to the worship of the sun.

Besides that the most solemn parts of the Christian worship were always performed on Sundays, this day was distinguished by a peculiar reverence and respect expressed towards it in the observation of some special laws and customs. Among these, we may reckon in the first place, those imperial laws which suspended all proceedings at law upon this day, excepting only such as were of absolute necessity, or eminent charity; such as the manumission of slaves, and the like. Neither was it only the business of the law, but all secular and servile employments were superseded upon this day, still excepting acts of necessity and mercy. Another thing which the christian laws took care of, to secure the honour and dignity of the Lord's day, was, that no ludicrous sports or games should be followed on this day; but all such recreations and refreshments as tended to the preservation or convenience of life were allowed of; and therefore, Sunday was always a day of feasting, and it was not allowable to fast thereon, not even in Lent. The great care and concern of the primitive christians in the religious observation of the Lord's-day, appears first from their constant attendance upon all the solemnities of public worship, from which nothing but sickness, imprisonment, banish-

ment, or some great necessity could detain them. Secondly, from their zeal in frequenting religious assemblies on this day, even in times of the hottest persecution, when they were often beset and seized in their meetings and congregations. Thirdly, from their studious observations of their vigils or nocturnal assemblies that preceded the Lord's-day. Fourthly, from their eager attendance on sermons, in many places twice upon this day, and their constant resorting to evening prayers, where there was no sermon. Lastly, from the severe censures inflicted on those who violated the laws concerning the religious observation of this day, such persons being usually punished with excommunication, as appears from the apostolical constitutions, and the canons of several councils. In the Romish breviary, and other offices, we meet with a distinction of Sundays, into those of the first and second class; Sundays of the first class are, Palm-sunday, Easter-sunday, Advent, Whit-sunday, &c. those of the second class are the common Sundays of the year.

By our laws, no person is to do any worldly labour on this day, which is set apart for the service and worship of God, except works of necessity and charity, under the penalty of five shillings. And if any person cry, or expose to sale any wares, or goods on a Sunday, the same will be forfeited to the poor, &c. the offender being convicted thereof before a justice of the peace, &c. who is authorized to cause the penalties and forfeitures to be levied by distress. Yet this extends not to dressing of meat, nor to the selling of milk in the morning or evening, or the selling of mackerel on that day. The Sunday is not a day in law, so that no process lies, or may be served thereon, except for treason, or felony, or an escape. A sale of goods, or contract made on a Sunday, is deemed void.

SUNDAY Letter. See DOMINICAL LETTER.

SUOVETAURILIA, an ancient Roman sacrifice, so called because it consisted of a pig, *sus*, a sheep, or rather ram, *ovis*, and a bull, *taurus*. They were all males to denote the masculine courage of the Roman people. It was likewise called solitaurilia, because the animals offered up were always, *solida*, whole or uncut.

SUPERCARGO, a person employed by merchants to go a voyage, and oversee their cargo, or lading, and dispose of it to the best advantage.

SUPERCILIUM, in anatomy, the hairy arch extended over the orbit of each eye.

SUPERCILIUM, in the ancient architecture, the uppermost member of the cornice, called by the moderns corona, crown, or larmier.

It is also used for a square member, under the upper tore in some pedestals; some authors confound it with the tore itself.

SUPEREROGATION, in theology, what a man does beyond his duty, or more than he was commanded to do. The Romanists stand up strenuously for works of supererogation, and maintain, that the observance of evangelical councils is such. By means of which, a stock of merit is laid up, which the church has the disposal of, and which she distributes in indulgences to such as need. The reformed church do not allow of any work of supererogation.

SUPERFETATION, *Superfœtatio*, in medicine, a second, or after conception, happening, when the mother, already pregnant, conceives of a later coition; so that she bears at once two fœtuses of unequal age and bulk, and is delivered of them at different times. We meet with instances of superfœtations in Hippocrates, Aristotle, Du Laurens, &c. But they are said to be much more frequent in hares and sows. Naturalists hold that female rats are frequently born with young rats in their wombs; and we are told of extraordinary instances of this kind in the female part of the human species, by Bartholine, Mentzelius, and in the History of the Royal Academy of Sciences.

SUPERFICIES, or SURFACE, in geometry, a magnitude considered as having two dimensions; or extended in length and breadth, but without thickness or depth. In bodies, the superficies is all that presents itself to the eye. A superficies is chiefly considered as the external part of a solid. When we speak of a surface

M m m

simply,

simply, and without any regard to body, we usually call it figure. The several kinds of superficies are as follows. Rectilinear superficies, that comprehended between right lines; curvilinear superficies, that comprehended between curve lines; plane superficies, is that which has no inequality, but lies evenly between its boundary lines; convex superficies, is the exterior part of a spherical, or spheroidal body; and a concave superficies, is the internal part of an orbicular or spheroidal body.

The measure or quantity of a superficies, or surface, is called the area thereof.

The finding of this measure, or area, is called the quadrature thereof.

To measure the surfaces of the several kinds of bodies, as spheres, cubes, parallelopipeds, pyramids, prisms, cones, &c. see SPHERE, &c.

Line of SUPERFICIES, a line usually found on the sector, and Gunter's scale, the description and use whereof, see under the article SECTOR and GUNTER'S SCALE.

SUPERFINE, in the manufactories, a term used to express the superlative fineness of a stuff; thus a cloth, a camblet, &c. are said to be superfine, when made of the finest wool, &c. or when they are the finest that can be made. The term is particularly used among gold or silver wire-drawers, for the gold or silver wire, which after being drawn through an infinite number of holes, each less and less, is at length brought to be no bigger than an hair.

SUPERINSTITUTION, *Superinstitutio*, denotes an institution upon another, as where AB is admitted and instituted to a benefice upon one title, and CD is admitted and instituted on that of another.

SUPERINTENDANT, in the French customs, an officer who has the prime management and direction of the finances or revenues of the king. The term is also used for the first officer of the queen's household, who has the chief administration thereof. They have also a superintendant of the buildings, answering to the surveyor of the works among us.

SUPERINTENDANT also denotes an ecclesiastical superior in several reformed churches, where episcopacy is not admitted, particularly among the Lutherans in Germany, and the Calvinists in some other places. The superintendant is in effect little other than a bishop, only his power is somewhat more restrained than that of the diocesan bishops. He is the chief pastor, and has the direction of all the inferior pastors within his district or diocese.

SUPERIOR, or SUPERIOUR, something raised above another, or that has a right to command another.

SUPERJURARE, was antiently a term used in our law where a criminal endeavoured to excuse himself by his own oath, or by the oath of one or two witnesses; and the crime charged against him was so notorious, that he was convicted upon the oaths of many more witnesses; this was termed superjurare.

SUPERLATIVE, in grammar, one of the three degrees of comparison, being that inflexion of nouns-adjective that serves to augment and heighten their signification, and shews the quality of the thing denoted to be in the highest degree.

In English, the superlative is usually formed by the addition of *est* to the positive, as *richest*, *greatest*, &c. and frequently by prefixing of *most*, as *most rich*, *most great*, &c.

SUPERNUMERARY, something over and above a fixed number. In several of the offices are supernumerary clerks, to be ready on extraordinary occasions. There are also supernumerary surveyors of the excise, to be ready to supply vacancies when they fall; these have but half-pay. In music, the supernumerary, called by the Greeks *proslambanomenos*, is the lowest of the chords of their system, answering to *a*, *mi*, *la*, of the lowest octave of the moderns.

SUPERONERATIONE PASTURÆ, in law, a judicial writ which lies against a person that is impleaded in the county-court, for furcharging of a common with his cattle, in a case where he was formerly impleaded for it in the same court, and the cause is removed into one of the courts at Westminster.

SUPERPARTICULAR, } See RATIO.
SUPERPARTIENS, }
SUPER-PRÆROGATIVA REGIS, in law, a writ that formerly lay against the king's widow, for marrying without a licence.

SUPER-PURGATION, *Hypercatharsis*, in medicine, an excessive over-violent purging, the usual effects of colliquating, corrosive and stimulating medicines. In the beginning of this disorder, a very thin matter is evacuated: but afterwards, when the relaxation and aperture of the vessels are increased, the necessary humours are discharged; there is first an excretion of yellow bile, then of phlegm, then of black bile, and last of all blood.

Those who labour under a superpurgation, must be treated with frictions of the skin, and a warm bath, drinking before they bathe thin, red, or yellow wine, for such is easiest of distribution, with sops of bread, and pomegranates.

If the evacuation continues, let the limbs be bound in such a manner, that the bandage may be carried from the upper to the lower parts. Exhibit also a small quantity of theriaca, to be taken with the flesh of vipers, or for want of that, troches of theriaca, or troches of seeds, and of the antidote called philonium. Cupping-glasses may also be applied to the stomach, and cataplasms of polenta and mulsum; after which, you may use astringent epithems, but the greatest relief is had from frictions of the whole body, and potable remedies. The patient should keep himself from cold air, or what is very warm. If the evacuation still continues, the aforesaid cataplasms should be applied, and obtundents injected in clysters, such as the fat of goose, sweet wine, oil of spike, and the like.

SUPERQUADRIPARTIENS. See the article RATIO.

SUPERSCAPULARIS INFERIOR, called also *infraspinatus*, a muscle that helps to draw the arm backwards. It covers all the space that is between the spine and the teres minor, and is inserted in the neck of the humerus.

SUPERSEDEAS, in law, according to Fitzherbert, is a writ which lies in divers cases; and in general signifies a command to stay some of the ordinary proceedings in law, which, on good cause shewn, ought not to proceed. It is likewise used for staying of an execution after a writ of error is allowed, and bail put in, but not before bail is given, in case there be a judgment upon verdict, or by default in debt, &c. A superseedeas is also granted by the court for setting aside an erroneous judicial process, &c. And a prisoner may be thereby discharged upon entering his appearance, and on the plaintiff's not filing a declaration against him. For this writ is as good a cause to discharge the person, as the first process is to arrest him. There is a further writ of superseedeas, where an audita querela is sued, and in cases of surety of the peace, when one is already bound to the peace in chancery, or elsewhere.

SUPERSTITION, extravagant devotion, or religion wrong directed, or conducted.

SUPERVISOR, a surveyor, or overseer.

It was formerly, and still remains a custom among some persons, to appoint a supervisor of a will, to see that the executors thereof do punctually observe and perform the same.

Supervisor formerly was used for surveyor of the highways. There are likewise certain officers of the excise, who are called supervisors, on account of their having the supervising and inspecting of the books, &c. of the inferior officers belonging to that branch of the revenue, to prevent their neglect of duty.

SUPINATORES, in anatomy, are two muscles, the longus and brevis; the first ariseth by a fleshy beginning three or four fingers breadth above the external extubance of the humerus. It lies all along the radius, to whose inferior and external part it is inserted by a pretty broad tendon; the last comes from the external and upper part of the ulna, and, passing round the radius, it is inserted into its upper and fore-part below the tendon of the biceps. These turn the palm of the hand upwards.

SUPINE

SUPINE, in Latin grammar, a part of the conjugation of a verb, of a like effect with the infinitive mood.

There are two kinds of supines, the one in *um*, whose signification is active, and marks a motion, as *dare nuptum*; the other in *u*, having a passive signification, as *horrendum auditu*, &c.—The supines have neither number nor person.

SUPPLEMENT of an Arch, in geometry, or trigonometry, is the number of degrees that it wants of being an intire semicircle; as a complement, signifies what an arch wants of being a quadrant.

SUPPLEMENT, in matters of literature, an appendage to a book, to supply what is wanting therein.

SUPPLICAVIT, a writ issuing out of Chancery, for taking surety of the peace when one is in danger of being hurt in his body by another.

SUPPORTED, in heraldry, a term applied to the uppermost quarters of a shield when divided into several quarters, these seeming as it were supported or sustained by those below. The chief is said to be supported when it is of two colours, and the upper colour takes up two thirds of it. In this case it is supported by the colour underneath.

SUPPORTERS, in heraldry, figures in an achievement placed by the side of the shield, and seeming to support or hold up the same. Supporters are chiefly figures of beasts: figures of human creatures, for the like purpose, are properly called tenants. Some make another difference between tenant and supporter: when the shield is borne by a single animal, it is called tenant; when by two, they are called supporters. The figures of things inanimate sometimes placed aside of escutcheons, but not touching or seeming to bear them, though sometimes called supporters, are more properly cotises.

The supporters of the British arms are a lion and an unicorn: those of the French arms are angels, &c.

In England, none under the degree of a banneret are allowed supporters, which are restrained to those called the high nobility. The Germans permit none but princes and noblemen of rank to bear them: but among the French the use of them is more promiscuous.

SUPPOSITION, in music, is when one of the parts dwells on a note, while another part makes two or more lesser notes equivalent to it, by conjoint degree. See **HARMONY**.

SUPPOSITORY, *Suppositorium*, in pharmacy, a kind of medicated cone, or ball, which is introduced to the anus for opening the belly. Suppositories are usually made of soap, sugar, alum, or a piece of tallow-candle, about the length of a man's thumb and the breadth of a finger, though they may be made smaller for children, and sometimes a little thicker for adults. Suppositories are sometimes compounded of ingredients adapted to the disease and circumstances of the patient, as of honey, salt, powder of aloes, colocynthia, and the like. If one suppository does not occasion a stool, it must be followed by another stronger one; and if that does not succeed, the repetition must be continued till the effect required is produced. They are sometimes lubricated with oil or butter, that they may be introduced with greater ease. Some use a lozenge of sugar, or a piece of thin linen cloth rolled up with a little lard or salt butter, which greatly loosens the belly. For ulcers of the rectum, the best suppositories are made of honey of roses, powder of mastich and myrrh, or of colophony. The stronger suppositories, which are composed of acrid and stimulating ingredients, are advantageously used in promoting a difficult birth, if the infant be in a natural position; and also for expelling the secundines when they are tenaciously retained in the uterus. In exhibiting them the patient should be put in the same posture as in giving a clyster, and the suppository must be gently thrust up the anus with the finger.

SUPPRESSION, in law, the extinction or annihilation of an office, right, rent, or the like.

SUPPRESSION, in grammar and rhetoric, denotes an omission of certain words in a sentence, which yet are necessary to full and perfect construction: as, "I come from my father's;" that is, "from my father's house."

Suppression is a figure of speech very frequent in our language, chiefly used for brevity and elegance. Some

rules relating hereto are as follow: 1. Whenever a word comes to be repeated in a sentence oftener than once, it is to be suppressed. Thus we say, "This is my master's horse," not "This horse is my master's horse." 2. Words that are necessarily supplied may be suppressed: and 3. All words that use and custom suppress in other languages, are also to be suppressed in English, unless there be particular reasons for the contrary.

Suppression is also a figure in speech whereby a person in rage, or other disturbance of mind, speaks not out all he means, but suddenly breaks off his discourse. Thus the gentleman in Terence extremely incensed against his adversary, accosts him with this abrupt saying, "Thou of all." The excess of his indignation and rage choaked the passage of his voice, and would not suffer him to utter the rest. But in these cases, though the discourse is not complete, the meaning is readily understood; and the evidence of the thought easily supplies the defect of words. Suppression sometimes proceeds from modesty, and fear of uttering any word of ill and offensive sound.

SUPPRESSION, in medicine, is generally used for a retention of urine or the menses.

SUPPRESSIONIS IGNIS, a fire of suppression, a term used in chemistry to express such an application of fire to any subject that it shall at once act upon it, both above and below, in the same manner. The usual way of giving this heat is by covering the vessel in which the ingredients are put with sand, and then laying hot coals upon that, so that they may heat through the sand downwards.

SUPPURATION, in medicine and surgery, the second way wherein an inflammation terminates, being a conversion of the inspissated blood and the soft adjacent parts, as the vessels and fat, into pus, or matter: which disorder, when it has not yet found an opening, is generally called an abscess.

The best cure of an inflammation is by resolution or dispersion; but when this is out of the power of the surgeon or physician to effect, and when tumours and phlegmons shew a tendency to suppuration, all the resolving and dispersing medicines must be laid aside, and great care must be taken to forward the maturity of the inflammation; that is, to convert the stagnated blood into laudable matter; then to give a discharge or vent to this suppurated matter; afterwards to cleanse the part; and finally to incarn and heal it.

In general, suppuration is to be promoted by such of the emollient medicines as obstruct the pores of the skin, as fats, oils, and glutinous medicines, which may be used in form of cataplasms or plasters. But to be more particular, suppurating medicines are the fats of a goose, of a dog, of a man, of a viper, and of a bear; pigeon and cow-dung; bran, yeast, herrings, leeches, melilot, tobacco, oil, burgundy pitch, common-pitch, rosin, deer-suet, ox-suet, sheep-suet, and frankincense. These medicines, either alone or compounded, are to be applied hot to the part, and the application frequently repeated, till the matter within is found to be sufficiently ripened by the softness and whiteness of the tumour: but when the abscess is small, it is sufficient and more convenient to apply some of the ripening plasters, as diachylon with the gums, or the like, till the suppuration is perfected.

In general, it is to be observed, that suppurative medicines are such as by the activity and warmth of their parts are able to penetrate the pores, and mix with and rarify any obstructed matter, so that it may be rendered fit to discharge, upon laying open the part by a caustic or incision. Now, in many instances, as the matter by this means rarifies and grows more fluid, the re-fluent blood is apt to wash it back into the common mass, which sometimes is of that nature as to do a great deal of mischief; or by making it take up more room upon its rarefaction, occasions it more to distend the parts in which it is contained, whereon a sense of pain is excited, and thereby a greater concourse of fluid, and consequently a needless increase of the tumour; so that medicines under this denomination require to be in the hand of such as are so well acquainted with the mechanism of the animal œconomy as to be able to apply them to the best advantage, and know how to avoid the hazards which

may

may arise from their abuse. Nor are internal remedies to be neglected in order to further a suppuration, especially when the tumours are large and of consequence. In these cases, when the blood moves too slowly, which may be known by the pulse, the patient must be allowed to eat meat, and must take such medicines as are warm and stimulating, by means of which, and by the increased motion of the blood, the inspissated particles contained in the smaller vessels will be the more easily converted into matter. Strong broths are very proper for this purpose, as also the use of wine, or ale, in moderation; and Venice treacle, diascordium, and the confection of al-kermes, are to be the medicines taken three or four times a day, and medicated teas made of saunders-wood, sassafras, or cinnamon. But on the contrary, when the motion of the blood is too violent, and the heat too great, cooling medicines are to be given, such as the thin and watery drinks, the sub-acid medicines, and nitre: bleeding in a small quantity is also often necessary in this case. But when the constitution is sound, and the blood's motion regular, the use of internal medicines to promote suppuration is trifling, and may be altogether rejected.

SUPPURATIVES, or SUPPURATING MEDICINES, such as promote suppuration.

SUPPUTATION. See **COMPUTATION.**

SUPRACOSTALES, or LEVATORES COSTARUM, in anatomy, muscles serving to respiration; being among those that dilate the thorax for that end, and therefore reckoned among the dilatores.

These muscles are of two kinds, being distinguished from their figures into short and long. The short ones are twelve on each side; they have their origin from the transverse processes of eleven vertebræ of the back, and of one that is in the lower one of the neck, and they are inserted into the hinder part of the ribs. The long supracostales are three or four: their origin is the same from the seventh, eighth, ninth, and tenth vertebræ, and their end in the ninth, tenth, eleventh, and twelfth ribs.

SUPRALAPSARY, in theology, a person who holds that God, without any regard to the good or evil works of men, has resolved, by an eternal decree, to save some and damn others. These are also called antelapsaries, and are opposed to sublapsaries and infralapsaries.

SUPRASPINATUS, in anatomy, a muscle thus called from its fleshy origination at the upper end of the basis of the scapula above the spine, to the upper part whereof it is connected, as also to the superior edge of the scapula, whence marching along the upper interscapulum, or thin part of the scapula, which it fills, it passes under the acromium, and articulation of the humerus. It helps to lift the arm upwards.

SUPREMACY, in our polity, the superiority or sovereignty of the king over the church as well as state, whereof he is established head.

The king's supremacy was at first established, or, as others say, recovered, by king Henry VIII. in 1534, after breaking with the pope. It is since confirmed by several canons, as well as by the articles of the church, and is passed into an oath which is required as a necessary qualification for all offices and employments both in church and state, from persons to be ordained, from the members of both houses of parliament, &c.

SURA, in anatomy, the calf, or fleshy part of the leg. The word is also used by some for the fibula. See **FIBULA.**

SURBATING, among farriers, is when the sole of a horse's foot is worn, bruised, or spoiled by beating the hoof against the ground in travelling without shoes, or going in hot sandy lands, or with a shoe that hurts the sole, lies too flat to it, or the like. Sometimes also it happens by over-riding a horse while young, before his feet are hardened; and sometimes by the hardness of the ground and high lifting his feet. The signs hereof are his halting on both fore-legs, and going stiffly, and creeping as if half foundered. In the general, there is nothing better for surbated feet than tar melted into the foot, or vinegar boiled with foot to the consistence of a

broth, and put into the foot boiling hot, with hurds over it, and splints to keep it in.

SURCHARGE, the same with overcharge, and whatever is above that which is just and right. Surcharge of the forest or a common, is when a commoner puts more beasts in the forest or common than he has a right to do.

SURCINGLE, a girdle wherewith the clergy of the church of England usually tie their cassock.

SURCOAT, a coat of arms to be worn over the body armour.

The surcoat is properly a loose thin taffaty-coat, with arms embroidered or painted on it, such as is worn by heralds: anciently also used by military men over their armour, to distinguish themselves by.

SURCULUS, in the anatomy of plants, a word used to express that part of the branching of the ribs of a leaf, which is of a middle kind betwixt the great middle rib and the smallest reticular ramifications. The middle rib is by the writers on these subjects called petiolum. The first division that go off laterally from these are called rami, or branches; the next division of these into more minute ones, furculi; and the final divarications of these into the reticular work that spreads itself over the whole leaf, capillamenta.

SURD, in arithmetic and algebra, implies any number or quantity that is incommensurable to unity; and is otherwise called an irrational number or quantity.

If a lesser quantity measures a greater so as to leave no remainder, as $2a$ measures $10a$, being found in it five times, it is said to be an aliquot part of it, and the greater is said to be a multiple of the lesser. The lesser quantity in this case is the greatest common measure of the two quantities; for as it measures the greater, so it also measures itself, and no quantity can measure it that is greater than itself.

When a third quantity measures any two proposed quantities, as $2a$ measures $6a$ and $10a$, it is said to be a common measure of these quantities; and if no greater quantity measure them both, it is called their greatest common measure.

Those quantities are said to be commensurable which have any common measure; but if there can be no quantity found that measures them both, they are said to be incommensurable; and if any one quantity be called rational, all others that have any common measure with it, are also called rational: but those that have no common measure with it, are called irrational quantities.

If any two quantities a and b have any common measure x , this quantity x shall also measure their sum or difference $a \mp b$. Let x be found in a as many times as unit is found in m , so that $a = mx$, and in b , as many times as unit is found in n , so that $b = nx$; then shall $a \mp b = mx \mp nx = m \mp n x$: so that x shall be found in $a \mp b$, as often as unit is found in $m \mp n$: now since m and n are integer numbers, $m \mp n$ must be an integer number or unit, and therefore x must measure $a \mp b$.

It is also evident, that if x measure any number as a , it must measure any multiple of that number. If it be found in a as many times as unit is found in m , so that $a = mx$, then it will be found in any multiple of a , as na , as many times as unit is found in mn ; for $na = mnx$.

If two quantities a and b are proposed, and b measure a by the units that are in m (that is, be found in a as many times as unit is found in m) and there be a remainder c , and if x be supposed to be a common measure of a and b , it shall be also a measure of c . For by the supposition $a = mb + c$, since it contains b , as many times as there are units in m , and there is c besides of remainder. Therefore $a - mb = c$. Now x is supposed to measure a and b , and therefore it measures mb , and consequently $a - mb$ which is equal to c .

If c measures b by the units in n , and there be a remainder d , so that $b = nc + d$, and $b - nc = d$, then shall x also measure d ; because it is supposed to measure b , and it has been proved that it measures c , and consequently nc , and $b - nc$, which is equal to d . Whence, as after subtracting b as often as possible from a , the remainder c is measured by x ; and after subtracting c as often as possible from b , the remainder d , is also measured by x ; so for

the same reason, if you subtract d , as often as possible from c , the remainder (if there be any) must still be measured by x ; and if you proceed, still subtracting every remainder from the preceding remainder, till you find some remainder which subtracted from the preceding leaves no further remainder, but exactly measures it, this last remainder will still be measured by x , any common measure of a and b .

The last of these remainders, viz. that which exactly measures the preceding remainder, must be a common measure of a and b ; suppose that d was this last remainder, and that it measured c by the units in r , then shall $c = rd$, and we shall have these equations,

$$\begin{aligned} a &= mb + c \\ b &= nc + d \\ c &= rd. \end{aligned}$$

Now it is plain that since d measures c , it must also measure nc , and therefore must measure $nc + d$, or b . And since it measures b and c , it must measure $mb + c$, or a ; so that it must be a common measure of a and b . But further, it must be their greatest common measure; for every common measure of a and b must measure d ; and the greatest number that measures d , is itself, which therefore is the greatest common measure of a and b .

But if, by continually subtracting every remainder from the preceding remainder, you can never find one that measures that which precedes it, exactly, no quantity can be found that will measure both a and b ; and therefore they will be incommensurable to each other.

For if there was any common measure of these quantities, as x , it would necessarily measure all the remainders c , d , &c. For it would measure $a - mb$, or c , and consequently $b - nc$, or d ; and so on; now these remainders decrease in such a manner, that they will necessarily become at length less than x , or any assignable quantity. For c must be less than $\frac{1}{2}a$; because c is less than b , and therefore less than mb , and consequently less than $\frac{1}{2}c + \frac{1}{2}mb$, or $\frac{1}{2}a$. In like manner d must be less than $\frac{1}{2}b$, for d is less than c , and consequently less than $\frac{1}{2}d + \frac{1}{2}nc$, or $\frac{1}{2}b$. The third remainder, in the same manner must be less than $\frac{1}{2}c$, which is itself less than $\frac{1}{2}a$: Thus these remainders decrease so that every one is less than the half of that which preceded it next but one. Now if from any quantity you take away more than its half, and from the remainder, more than its half, and proceed in this manner, you will come at a remainder less than any assignable quantity. It appears therefore that if the remainders c , d , &c. never end, they will become less than any assignable quantity, as x , which therefore cannot possibly measure them, and therefore cannot be a common measure of a and b .

In the same way, the greatest common measure of two numbers is discovered. Unit is a common measure of all integer numbers, and two numbers are said to be prime to each other, when they have no greater common measure than unit. Such as 9 and 25. Such always are the least numbers that can be assumed in any given proportion; for if these had any common measure, then the quotients that would arise by dividing them by that common measure would be in the same proportion, and being less than the numbers themselves, these numbers would not be the least in the same proportion; against the supposition.

The least numbers in any proportion always measure any other numbers that are in the same proportion. Suppose a and b to be the least of all integer numbers in the same proportion, and that c and d , are other numbers in that proportion, then will a measure c , and b measure d .

For if a and b are not aliquot parts of c and d , then they must contain the same number of the same kind of parts of c and d , and therefore dividing a into parts of c , and b into an equal number of like parts of d , and calling one of the first m , and one of the latter n ; then as m is to n , so will the sum of all the m 's, be to the sum of all the n 's; that is, $m : n :: a : b$, therefore a and b will not be the least in the same proportion; against the supposition. Therefore a and b must be aliquot parts of c and d . Hence we see that numbers which are prime to each other are the least in the same proportion; for if there were others in the same proportion less than them, these would measure them by the same number,

which therefore would be their common measure against the supposition, for we supposed them to be prime to each other.

If two numbers a and b are prime to one another, and a third number c measures one of them a , it will be prime to the other b . For if c and b were not prime to each other, they would have a common measure, which because it would measure c , would also measure a , which is measured by c , therefore a and b would have a common measure; against the supposition.

If two numbers a and b are prime to c , then shall their product ab be also prime to c : For if you suppose them to have any common measure as d , and suppose that d measures ab by the units in e , so that $de = ab$, then shall $d : a :: b : e$. But since d measures c , and c is supposed to be prime to a , it follows that d and a are prime to each other; and therefore d must measure b ; and yet since d is supposed to measure c which is prime to b , it follows that d is also prime to b : that is, d is prime to a number which it measures, which is absurd.

It follows that if a and c are prime to each other, then a^2 will be prime to c : For by supposing that a is equal to b , then ab will be equal to a^2 ; and consequently a^2 will be prime to c . In the same manner c^2 will be prime to a .

If two numbers a and b , are both prime to other two c , d , then shall the product ab be prime to the product cd ; for ab will be prime to c and also to d , and therefore cd will be prime to ab .

From this it follows, that if a and c are prime to each other, then shall a^2 be prime to c^2 , by supposing, in the last, that $a = b$, and $c = d$. It is also evident that a^3 will be prime to c^3 , and in general any power of a to any power of c whatsoever.

Any two numbers, a and b , being given, to find the least numbers that are in the same proportion with them, divide them by their greatest common measure x , and the quotients c and d shall be the least numbers in the same proportion with a and b .

For if there could be any other numbers in that proportion less than c and d , suppose them to be e and f , and these being in the same proportion as a and b would measure them: And the number by which they would measure them, would be greater than x , because e and f are supposed less than c and d , so that x would not be the greatest common measure of a and b ; against the supposition.

Let it be required to find the least number that any two given numbers as a and b can measure. First, if they are prime to each other, then their product ab is the least number which they can both measure.

For if they could measure a less number than ab as c , suppose that c is equal to ma , and to nb ; and since c is less than ab , therefore ma will be less than ab , and m less than b ; and nb being less than ab , it follows that n must be less than a ; but since $ma = nb$, and consequently $a : b :: n : m$, and a and b are prime to each other, it would follow that a would measure n , and b measure m , that is a greater number would measure a less, which is absurd.

But if the numbers a and b are not prime to each other, and their greatest common measure is x , which measures a by the units in m , and measures b by the units in n , so that $a = mx$, and $b = nx$, then shall an (which is equal to bm , because $a : b :: mx : nx :: m : n$, and therefore $an = bm$) be the least number that a and b can both measure. For if they could measure any number c less than na , so that $c = la = kb$, then $a : b :: m : n :: k : l$; and because x is supposed to be the greatest common measure of a and b , it follows that m and n are the least of all numbers in the same proportion, and therefore m measures k , and n measures l . But as c is supposed to be less than na , that is, la less than na , therefore l is less than n , so that a greater would measure a lesser, which is absurd. Therefore a and b cannot measure any number less than an ; which they both measure because $na = mb$.

It follows from this reasoning, that if a and b measure any quantity c , the least quantity na which is measured by a and b , will also measure c . For if you sup-

N n n

pose

pose as before that $c=la$, you will find that n must measure l , and na must measure la or c .

Let a express any integer number, and $\frac{m}{n}$ any fraction reduced to its lowest terms, so that m and n may be prime to each other, and consequently $an+m$ also prime to n , it will follow that $\frac{an+m}{n^2}$ will be prime to n^2 , and consequently $\frac{an+m}{n^2}$ will be a fraction in its least terms, and can never be equal to an integer number. Therefore

the square of the mixt number $a + \frac{m}{n}$ is still a mixt number and never an integer. In the same manner the cube, biquadrate, or any power of a mixt number, is still a mixt number and never an integer. It follows from this, that the square root of an integer must be an integer or an incommensurable. Suppose that the integer proposed is B , and that the square root of it is less than $a+1$, but greater than a , then it must be an incommensurable; for if it is a commensurable, let it be $a + \frac{m}{n}$, where $\frac{m}{n}$ represents any fraction reduced to

its least terms: it would follow that $a + \frac{m}{n}$ squared would give an integer number B , the contrary of which we have demonstrated.

It follows from the last paragraph, that the square roots of all numbers but of 1, 4, 9, 16, 25, 36, 49, 64, 81, 100, 121, 144, &c. (which are the squares of the integer numbers 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, &c.) are incommensurables; after the same manner, the cube roots of all numbers but of the cubes of 1, 2, 3, 4, 5, 6, 7, 8, 9, &c. are incommensurables: and quantities that are to one another in the proportion of such numbers must also have their square roots or cube roots incommensurable.

The roots of such numbers being incommensurable are expressed therefore by placing the proper radical sign over them; thus, $\sqrt{2}$, $\sqrt{3}$, $\sqrt{5}$, $\sqrt{6}$, $\sqrt{7}$, $\sqrt{8}$, $\sqrt{10}$, &c. express numbers incommensurable with unit. These numbers, tho' they are incommensurable themselves with unit, are commensurable in power with it, because their powers are integers, that is, multiples of unit. They may also be commensurable sometimes with one another, as the $\sqrt{8}$, and the $\sqrt{2}$, because they are to one another as 2 to 1: And when they have a common measure, as $\sqrt{2}$ is the common measure of both, then their ratio is reduced to an expression in the least terms, as that of commensurable quantities, by dividing them by their greatest common measure. This common measure is found as in commensurable quantities, only the root of the common measure is to be made their common divisor. Thus, $\frac{\sqrt{12}}{\sqrt{3}} = \sqrt{4} = 2$, and $\frac{\sqrt{18a}}{\sqrt{2}} = 3\sqrt{a}$.

A rational quantity may be reduced to the form of any given surd, by raising the quantity to the power that is denominated by the name of the surd, and then setting the radical sign after it thus, $a = \sqrt{a^2} = \sqrt[3]{a^3} = \sqrt[4]{a^4} = \sqrt[5]{a^5} = \sqrt[n]{a^n}$, and $4 = \sqrt{16} = \sqrt[3]{64} = \sqrt[4]{256} = \sqrt[5]{1024} = \sqrt[n]{4^n}$.

As surds may be considered as powers with fractional exponents, they are reduced to others of the same value that shall have the same radical sign by reducing these fractional exponents to fractions having the same value and a common denominator. Thus $\sqrt[n]{a} = a^{\frac{1}{n}}$ and $\sqrt[m]{a} = a^{\frac{1}{m}}$, and $\frac{1}{n} = \frac{m}{nm}$, $\frac{1}{m} = \frac{n}{nm}$, and therefore $\sqrt[n]{a}$ and $\sqrt[m]{a}$, reduced to the same radical sign, become $\sqrt[nm]{a^m}$ and $\sqrt[nm]{a^n}$. If you are to reduce $\sqrt{3}$ and $\sqrt[3]{2}$ to the same denominator, consider $\sqrt{3}$ as equal to $3^{\frac{1}{2}}$, the $\sqrt[3]{2}$ as equal to $2^{\frac{1}{3}}$, whose indices reduced to a common denominator, you have $3^{\frac{2}{6}} = 3^{\frac{1}{3}}$ and $2^{\frac{2}{6}} = 2^{\frac{1}{3}}$, and consequently $\sqrt{3} = \sqrt[6]{3^2} = \sqrt[6]{27}$, and $\sqrt[3]{2} = \sqrt[6]{2^2} = \sqrt[6]{4}$; so that the proposed surds $\sqrt{3}$ and $\sqrt[3]{2}$ are reduced to

other equal surds $\sqrt[6]{27}$ and $\sqrt[6]{4}$, having a common radical sign.

Surds of the same rational quantity are multiplied by adding their exponents, and divided by subtracting them;

thus, $\sqrt{a} \times \sqrt{a} = a^{\frac{1}{2}} \times a^{\frac{1}{2}} = a^{\frac{1}{2} + \frac{1}{2}} = a^1 = a$; and $\frac{\sqrt{a}}{\sqrt{a}} = \frac{a^{\frac{1}{2}}}{a^{\frac{1}{2}}} = a^{\frac{1}{2} - \frac{1}{2}} = a^0 = 1$; $\sqrt[3]{a} \times \sqrt[3]{a} = a^{\frac{1}{3}} \times a^{\frac{1}{3}} = a^{\frac{2}{3}} = \sqrt[3]{a^2}$; $\sqrt[3]{a} \times \sqrt[3]{a} \times \sqrt[3]{a} = a^{\frac{1}{3}} \times a^{\frac{1}{3}} \times a^{\frac{1}{3}} = a^1 = a$; $\sqrt{2} \times \sqrt{2} = \sqrt{2^2} = 2$; $\sqrt[3]{2} \times \sqrt[3]{2} \times \sqrt[3]{2} = \sqrt[3]{2^3} = 2$.

If the surds are of different rational quantities, as $\sqrt{a^2}$ and $\sqrt{b^2}$, and have the same sign, multiply these rational quantities into one another, or divide them by one another, and set the common radical sign over their product or quotient. Thus, $\sqrt{a^2} \times \sqrt{b^2} = \sqrt{a^2 b^2}$; $\sqrt{2} \times \sqrt{5} = \sqrt{10}$; $\frac{\sqrt{a^2}}{\sqrt{b^2}} = \sqrt{\frac{a^2}{b^2}} = \frac{a}{b}$.

$\sqrt{\frac{a^2}{b^2}} = \frac{a}{b}$; $\frac{\sqrt{9}}{\sqrt{24}} = \sqrt{\frac{9}{24}} = \sqrt{\frac{3}{8}} = \frac{1}{2} \sqrt{\frac{3}{2}}$.

If the surds have not the same radical sign, reduce them to such as shall have the same radical sign, and proceed as before, $\sqrt{a} \times \sqrt[n]{b} = \sqrt[n]{a^n b}$; $\frac{\sqrt{a}}{\sqrt[n]{b}} = \sqrt[n]{\frac{a^n}{b}}$.

$\sqrt{\frac{a^n}{b}} = \sqrt[n]{\frac{a^n}{b}}$; $\sqrt{2} \times \sqrt[3]{4} = 2^{\frac{1}{2}} \times 4^{\frac{1}{3}} = 2^{\frac{1}{2}} \times 2^{\frac{2}{3}} = 2^{\frac{1}{2} + \frac{2}{3}} = 2^{\frac{7}{6}} = \sqrt[6]{2^7}$.

$\sqrt{8 \times 16} = \sqrt{128}$; $\frac{\sqrt{4}}{\sqrt{2}} = \frac{2^{\frac{1}{2}}}{2^{\frac{1}{2}}} = \frac{2^{\frac{1}{2}}}{2^{\frac{1}{2}}} = 1$.

$\sqrt{\frac{16}{8}} = \sqrt{2}$. If the surds have any rational coefficients, their product or quotient must be prefixed; thus,

$2\sqrt{3} \times 5\sqrt{2} = 10\sqrt{6}$.

The powers of surds are found as the powers of other quantities, by multiplying their exponents by the index of the power required; thus, the square of $\sqrt{2}$ is $2^{\frac{1}{2}} \times 2 = 2^1 = 2$; the cube of $\sqrt[3]{5}$ is $5^{\frac{1}{3}} \times 3 = 5^1 = 5$. Or you need only, in involving surds, raise the quantity under the radical sign to the power required, continuing the same radical sign; unless the index of that power is equal to the name of the surd, or a multiple of it, and in that case the power of the surd becomes rational. Evolution is performed by dividing the fraction, which is the exponent of the surd, by the name of the root required. Thus the square root of $\sqrt[3]{a^3}$ is $\sqrt{a^3}$ or $\sqrt[6]{a^6}$.

The surd $\sqrt[n]{a^m x^m} = a \sqrt[n]{x^m}$; and, in like manner, if a power of any quantity of the same name with the surd divides the quantity under the radical sign without a remainder, as here a^m divides $a^m x$, and 25 the square of 5 divides 75 the quantity under the sign in $\sqrt{75}$ without a remainder: then place the root of that power rationally before the sign, and the quotient under the sign, and thus the surd will be reduced to a more simple expression. Thus $\sqrt{75} = 5\sqrt{3}$; $\sqrt[3]{48} = \sqrt[3]{3 \times 16} = 2\sqrt[3]{3}$; $\sqrt[3]{81} = \sqrt[3]{27 \times 3} = 3\sqrt[3]{3}$.

When surds are reduced to their least expressions, if they have the same irrational part, they are added or subtracted, by adding or subtracting their rational coefficients, and prefixing the sum or difference to the common irrational part. Thus, $\sqrt{75} + \sqrt{48} = 5\sqrt{3} + 4\sqrt{3} = 9\sqrt{3}$; $\sqrt[3]{81} + \sqrt[3]{24} = 3\sqrt[3]{3} + 2\sqrt[3]{3} = 5\sqrt[3]{3}$; $\sqrt{150} - \sqrt{54} = 5\sqrt{6} - 3\sqrt{6} = 2\sqrt{6}$; $\sqrt{a^2 x} + \sqrt{b^2 x} = a\sqrt{x} + b\sqrt{x} = (a+b)\sqrt{x}$.

Compound surds are such as consist of two or more joined together. The simple surds are commensurable in power, and by being multiplied into themselves give at length rational quantities; yet compound surds multiplied into themselves commonly give still irrational products.

ducts. But, when any compound surd is proposed, there is another compound surd which multiplied into it gives a rational product. Thus $\sqrt{a} + \sqrt{b}$ multiplied by $\sqrt{a} - \sqrt{b}$ gives $a - b$, and the investigation of that surd which multiplied into the proposed surd will give a rational product.

SURETY, in law, generally signifies the same with bail.

There is also a surety of the peace, whereby a person, in danger of hurt from another, is secured by a bond or recognizance, acknowledged by the other to the king, and bail bound with him for keeping the peace.

SURFEIT, in medicine, a sickness proceeding from the sensation of a load at the stomach, usually attended with eruptions, and sometimes with a fever.

Surfeits may be caused, says Dr. Shaw, 1. By voracity; from whence the stomach and intestines are overcharged, digestion weakened, and the chyle rendered crude or viscid, and the blood corrupted. If what was thus devoured were high seasoned or inflammatory, or happened to lie longer in the body, it is supposed to cause a fever also. 2. By drinking of small liquors in hot weather, or when the body is heated by exercise; which, perhaps, chills the fluids, and gives a check to perspiration; from whence also may arise a fever and eruptions. Summer fruits likewise, as cucumbers, apples, cherries, &c. may have the same effect. 3. By too great exercise or heat, whence the fluids are rarified and thrown into too rapid a circulation, which being suddenly stopped, as may happen by cooling too fast, there ensues also a stoppage of perspiration. 4. By the state or some change of the air; as by blasts, or vehemently hot and sultry weather, or cold winds giving a check to, and preventing, perspiration.

Eruptions may not appear in surfeits, either by reason of the slightness of the cause, or some wrong management at the first. Nausea's, oppression, sickness, and sometimes a vomiting and a fever, but seldom eruptions, attend on an overloaded stomach. This species of a surfeit is called *crapula*; sickness, gnawing at the stomach, sometimes eruptions and a fever attend surfeits, from the bad quality of any thing used as food. The fever always decreases as the eruptions increase; and if these suddenly disappear, the fever increases. Those surfeits, which proceed from too great exercise, or too sudden cooling after it, appear with sickness, a fever and eruptions, though the two last may be wanting. Those caused from some alteration in the air, and vulgarly called *blasts*, appear with redness of the face, spots, and a fever, often with blisters on the skin.

SURGERY, or **CHIRURGERY**. See the article **CHIRURGERY**.

SURMOUNTED, in heraldry, is when one figure is laid over another.

SURNAME, or **SIRNAME**, a name added to the proper or baptismal name to denominate the person of such a family.

SURREBUTTER, in law, a second rebutter, or the replication of the plaintiff to the defendant's rebutter.

SURRENDER, in common law, an instrument in writing, testifying, that the particular tenant of lands and tenements for life, or years, doth sufficiently consent and agree, that he who has the next or immediate remainder or reversion thereof, shall have the present estate of the same in possession, and that he hereby yields and gives up the same to him.

SURSOLID, or **SURDESOLID**, in arithmetic and algebra, the fifth power, or fourth multiplication of any number or quantity considered as a root.

SURSOLID PROBLEM, in mathematics, is that which cannot be resolved but by curves of a higher nature than a conic section; v. gr. in order to describe a regular endecagon, or figure of eleven sides in a circle, it is required to describe an isosceles triangle on a right line given, whose angles at the base shall be quintuple to that at the vertex; which may easily be done by the intersection of a quadratrix, or any other curve of the second gender.

SURVEYING, the art or act of measuring lands; i. e. of taking the dimensions of any tract of ground,

laying down the same in a map or draught, and finding the content or area thereof.

Surveying, called also *geodæsia*, is a very ancient art; it is even held to have been the first or primitive part of geometry, and that which gave occasion to, and laid the foundation of all the rest.

Surveying consists of three parts or members; the first is the taking of the necessary measures, and making the necessary observations on the ground itself; the second is the laying down of these measures and observations on paper: and the third, the finding the area or quantity of the ground thus laid down. The first is what we properly call surveying: the second we call plotting or protracting, or mapping: and the third casting up.

The first, again, consists of two parts, viz. the making of observations for the angles, and the taking of measures for the distances.

The former of these is performed by some one or other of the following instruments, viz. the theodolite, circumferentor, semi-circle, plain table, or compass: the description and manner of using each whereof, see under its respective article.

The latter is performed by means either of the chain or the perambulator: the description and manner of applying each whereof, see under its respective article.

The second branch of surveying is performed by means of the protractor, and plotting scale. See the article **PLOTTING**.

The third is performed by reducing the several divisions, inclosures, &c. into triangles, squares, trapeziums, parallelograms, &c. but especially triangles; and finding the areas or contents of these several figures.

SURVEYING Harbours.—Let plate CXXIII. fig. 5. represent the place which it is required to survey and draw a map of.

1. It will be requisite to have some idea of the place to be surveyed, therefore it will be necessary, before the work is begun, to walk several times along the coast, carefully observing the several particulars necessary to be taken notice of.

2. Having acquired an idea of the place, signals must be erected at every angle, &c. as at C, D, E, F, G, H, and I; also at the ends of the sands, &c. as at Q, S, T, V, W, X, Y, and Z. And when you are at the point Q, erecting the signal, observe what objects on the land are in a right line, which are the windmill at *t* and the church at K, which objects must be inserted in your map as a mark for ships to avoid the sand Q T W. Likewise, when you are in the midst of the channel between the ends of the sands W and X, observe what objects are in a direct line, which are the house at *w*, and the church at O. In like manner when you are at *y*, the two windmills at P and L will be in a right-line, as will the windmill at P and the church at K when you are at Z. These objects you must be careful to insert in your map, and, if there be none that will answer the intention, some ought to be erected.

3. The signals, &c. being erected, place your instrument at A, and observe the bearing of the signal at C; also the several angles comprehended between the lines A Q, A S, A T, A Y, and A Z, and the line A C. And, because the object at X will be in a right-line with that at T, therefore the angle will be the same.

4. Measure along the line A C with your chain or perambulator, and, when you come to R, note down the distance from A to R, and, fixing your instrument in the same situation as at A, observe the angles intercepted between the lines R V and R W and the line R C. And, because the windmill at *t* is in a perpendicular direction to the line A C in the point R, measure the distance from thence to that windmill, noting it down also in your book.

5. Continue the measuring of the line A C from R towards C, observing if the edge of the water is not parallel to the line A C, to measure the distance in a perpendicular direction, as the small perpendiculars *a*, *b*, *c*, &c. but be sure to remark the distance such perpendiculars are from the point A, or first station. Also, when you perceive that the windmill at P is in a perpendicular direction to the line A C, measure the distance *d* P.

6. When

6. When you have measured to B, fix your instrument there in the same position as at A, and observe the angles which the lines BY and BZ form with the line BC. Then turn the instrument about (the index being fixed at the beginning of the graduations) till through the sights you see the object at A, and fix the instrument by the screw in that position; then observe the angles comprehended between the line BA and the lines BX, BW, BV, BS, BT, and BQ. Also turning about the brass limb of the instrument (the index being fixed at the beginning of the graduations) till the two sights be in a right-line with the object at A, and, fastening the instrument in this position, take the angles intercepted between the line BA and the lines BM, BL, and BK, and measure the distance BM.

7. Having measured the whole line AC, fix your instrument at C in the same position as before, and take the angles BCD, and DCE, measuring the distance CD and the perpendicular *f*.

8. Remove your instrument to D, and take the angle CDE; that is, place the instrument at D, and, having fixed the index at the beginning of the graduations, turn the instrument about till you perceive through the sights the object at C, and fix the instrument in that position; then move the index till you see through the sights the object at E, and the degrees cut by the index will be the angle required.

9. Remove the instrument to M, and take the angles KMB and KML after the preceding manner.

10. Having observed the angles and measured the distances requisite on the west side of the harbour, remove your instrument to the other side and plant it at E, observing the bearing of the line EF, measuring its distance, together with that of the perpendicular *g*, in all respects as before; as also the lines FG, GH, HI, and their perpendiculars *hik*, continuing the perpendicular *b* to the end of a ledge of rocks lying off that point.

11. Because the cleft will interrupt your sight from the church at O, therefore you must place your instrument on the top of the cleft at *q*, and take the bearing of the church, and either measure the distance from your instrument to it, or else remove your instrument thither, and, having placed signals at *q* and *s*, take the angle *qOs*.

12. Remove your instrument at low-water to the sand at X, taking the bearings, and measuring the distances of the lines X*l* and *lr*, together with the perpendiculars *m*, *n*, *o*.

Having finished your observations, proceed to construct your map in the following manner:

1. Draw the east and west line BC, setting off on it the several distances, viz. from A to R, A to *a*, &c. then by drawing the several perpendiculars, and making them of their proper lengths, you may easily draw the track of the surface of the water, and those which are above the line will give the places where the several objects are to be delineated.

2. By the help of your protractor or line of chords, make the several angles at A, and R, equal to their respective number of degrees, &c. drawing a right-line through each, which continue at pleasure.

3. Construct the angles at B in the same manner, continuing the right-lines from this station till they cut those projected from A and R, which will be the true places of those objects; whence the sands Q, Y, and Z, may be easily drawn.

4. By projecting the angle ABM, and setting off on the line BM its proper distance, you will have the place where that church must be delineated.

5. Construct the angles BCD and DCE, continuing the line CE at pleasure, and set off its proper length on the line CD; then by drawing the perpendicular *f* of its proper length, you may draw that part of the harbour between C and D.

6. Construct the angle at D, continuing the line DE till it cuts CE in E, which will give the place of the station at E.

7. By constructing the angles ABK, ABL, BMK, and KML; and continuing the lines BK, BL, MK, and ML, till they cut each other in K and L; you will have the situation of the objects at K and L.

8. Proceed in the same manner on the other side of the harbour, by projecting the lines EF, FG, GH, and HI, according to their several bearings, &c. and by drawing the several perpendiculars of their true length, the track of the surface of the water on the east side of the harbour may be delineated; also, by continuing the perpendicular *b*, you will have the situation of the ledge of rocks lying off that point.

9. Observe to draw the appearance of the land; that is, from A to *d*, the sand-hills which lie along above the high-water mark, and the cleft which stretches all along the east side of the harbour.

10. In some convenient place draw the compass, but let it be in its true position without any variation; that is, observe to allow for the variation, if any, which must also be done before you begin your projection.

11. Draw the lines Q*rk*, QPM, *zwO*, *yPL*, and ZPK, which will shew the marks necessary to be observed by ships in coming into the harbour.

12. At low-water go off in your boat, and sound the depth of the water in various places, which insert in your map; and observe the setting of the tide, which you must represent by darts. Also the time of high-water at the full and change of the moon must be inserted in Roman numbers.

13. Lastly, in some convenient place of your map insert a scale, of the same length of that which you made use of in the projection.

SURVEYOR, one that hath the oversight and care of considerable works, lands, or the like.

Such are the surveyor-general of the king's manors, surveyor of the king's exchange, surveyor-general of the works, surveyor-general of the crown lands, &c.

SURVEYOR of the Minting, is an officer of the mint, whose office is to see the bullion cast out, and that it be not altered after the delivery of it to the melter.

SURVEYOR of the Navy, an officer whose business is to know the state of all stores, and see the wants supplied; to survey the hull, masts, and yards of ships; to audit the boatswains and carpenters accounts, &c.

SURVEYOR of the Ordnance, is an officer whose charge is to survey all the king's ordnance, stores, and provisions of war, in custody of the store-keeper of the Tower of London; to allow all bills of debts, to keep checks on labourers and artificers work, &c.

SURVEYOR, is also used for a gauger. And also for a person who measures and makes maps of land.

SUSPENSION, in mechanics, are those points in the axis or beam of a ballance, wherein the weights are applied, or from which they are suspended.

SUSPENSION of Arms, in war, is a short truce which the contending parties agree on, for the burial of their dead, the waiting for succours, or the order of their masters, &c.

SUSPENSION, in rhetoric, is the carrying on a period or discourse, in such a manner as to keep the reader in expectation of something considerable in the conclusion. But great care must be taken, that the reader's expectation be not disappointed; for nothing is more contemptible, than to promise much and perform little, or to usher in an arrant trifle with the formality of preface, and solemn preparation.

SUSPENSOR, in anatomy, the same with the cremaster muscle. See CREMASTER.

SUSPICION, in law. Persons may be taken up upon suspicion, where a felony is committed, &c. however, there must be at least some reasonable grounds for the same.

SUSPIRAL, a spring of water passing under ground towards a conduit or cistern. Also a breathing hole or ventiduct.

SUSSEX Marble, a name given by many to a peculiar species of marble found in the county, the name of which it bears, and formerly much used in the pillars of churches, and other buildings, but now less in esteem. The ground of this marble is grey, with a faint cast of green, and it is very thick set in all parts with shells: these are chiefly of the turbinated kind, and they are generally filled with a white spar, which adds very greatly to the beauty of the stone.

It is plain, from considering the whole mass of this marble, that this spar was received into the shells before they were deposited in the marble. This is about the hardness of the common white Genoese marble, if any thing, somewhat more hard. The slender round scapi of the pillars in Westminster-Abbey, and in many other of our Gothic buildings, are made of this kind of marble. Some people have thought that the scapi of pillars of this kind, which occur in most of our Gothic buildings, are artificial, and that they are a kind of fusile marble cast in cylindric moulds. But any one who will compare the marble, of which those pillars are made, with its shells, and the spar they are filled with, with the marble of Sussex quarries, will find both to be the same in every particular. *Woodward's Cat. of Foss.*

SUTURE, *Sutura*, in anatomy, is a particular articulation. The bones of the cranium are joined to one another by four sutures. The first is called the coronalis. It reaches transversely from one temple to the other. It joins the os frontis to the ossa parietalia and petrosa. The second is called lambdoidalis, because it resembles the Greek letter (Λ) lambda. It joins the os occipitis to the ossa parietalia and petrosa. The third is called sagittalis; it begins at the top of the lambdoidalis, and runs straight to the middle of the coronalis. It joins the two ossa parietalia together. The fourth is called sutura squamosa, because the parts of these bones which are joined by this future, are as it were cut slopewise and lapped over one another.

This future joins the semicircular circumference of the ossa temporum to the os sphenoides occipitis, and to the ossa parietalia. The first three sutures were called *futurae verae*; and the last sutura falsa, because it was supposed to have no indentations, which is false.

The bones of the cranium are not only joined to one another, but they are also joined to the bones of the upper jaw by three other sutures. The first is the transversalis; it runs across the face, it passes from the little angle of the eye, down to the bottom of the orbit, and up again by the great angle of the eye, over the root of the nose, and so to the little angle of the other eye. It joins the os frontis to the bones of the upper jaw. The second is the ethmoidalis; it surrounds the bone of that name, and joins it to the bones which are about it. The third is the sutura sphenoidalis; it surrounds the os sphenoides, joins it to the os occipitis, the ossa petrosa, and the os frontis.

SUTURE, in chirurgery, denotes a seam made to close the lips of a wound, in order to its healing.

The ancients invented a great variety of sutures, which they reduced to three kinds; incarnatives, restrictives, and conservatives.

Incarnative SUTURE, is thus called, because, by re-joining the edges of a wound, and keeping them together by means of a thread run across them with a needle, they grow together, and incarnate as before.

This they subdivided into five kinds, viz. the interrupted, intertwisted, pinned, or feathered, with clasps, and the dry future.

Of these five, two are perfectly disused, viz. the feathered future, and the future with clasps, as being too barbarous, and at the same unnecessary. The first was called pinned, when little pins were made use of; and feathered, when the barrels of feathers or quills were used.

To perform it, two or three needles, threaded with a double thread, were passed through the lips of the wound at a finger's breadth from each other, and a pin or feather put in the stitch; and another pin or feather bound with the ends of the same thread, that the feathers might keep the lips of the wound close together.

To perform the second, they had large, crooked clasps, pointed at each end; one of which they thrust into the upper part of the wound, the other into the lower, to bring the lips together. These sutures, cruel as they were, are yet known to be useless; for in the only cases where they should seem serviceable, viz. in deep wounds, where the contraction of the fleshy parts keeps the lips far asunder, and in wounds of tendons; they expose the patient to terrible convulsions and shudderings, which are avoided, by diminishing the dilata-

tion of the wounds, by moderate compressions, and waiting till the fibres relax.

Restrictive SUTURES, were those wherewith they endeavoured to stop the flux of blood from large wounds, where any considerable vessels were cut.

To this end, they invented several kinds, in the number whereof, were the shoe-makers, taylors, skimmers, and other seams, each more impertinent than other. It is evident, the very design of such a future is blameable: for supposing the wound so exactly sewed up, that no blood could escape through the lips thereof; yet will it still flow out of the vessels, and will thus be forced to make its way between the laminæ of the muscles, by which means the part will swell, rot, and gangrene. Yet, the skimmers future, *sutura pellionum*, is still in use for wounds of the intestines: it is thus called, because the skimmers use the like, in sewing up the holes made by the butchers, in flaying off the skin.

Conservative SUTURE, is that kind of ancient future, whereby the lips of large wounds, wherein there was a loss of substance, were prevented from receding too far. But a bandage, now, suffices.

Intertwisted SUTURE, is thus called, because, the needles being left sticking in the wound, the thread is wound around them; much after the same manner as the taylors do the threaded needles they keep in their sleeves, &c. This future is performed two ways; for either the needles are passed a-cross the wound, or they are stuck on the sides thereof.

All the sutures, hitherto mentioned, are made with needle and thread: besides which, there is another kind called dry sutures, which are performed with glue or size, or other proper viscous matter.

The dry SUTURE, is ordinarily made with small pieces of leather, on linen cloth, indented like a saw, so that the teeth may fall between each other, and the whole row may be closed. The cloth, before it is cut into this form, is spread with some proper plaister, in order to its firm adhesion.

The plaisters thus prepared, being cut into the form, are applied on the firm flesh, according to the length of the wound, reaching from it to the distance of some inches; and after they are dried, or well fastened to the part, the lips of the wound being approached, they may conveniently be held together by the future in that posture.

This kind of future is principally used for wounds in the face, to prevent unsightly scars: it is likewise convenient when the fibres of the muscles are cut a-cross, and where it is difficult or impossible to apply a bandage.

In the other kinds of sutures, the stitches ought always to be taken of a depth proportionable to that of the wound; care being had to avoid the nerves as much as possible. In long wounds they are best begun at the ends, but in short ones at the middle.

SWALLOW'S TAIL, in fortification, a kind of out-work, only differing from a single tenaille, in that its sides are not parallel as those of the tenaille, but narrower towards the fortified place, than towards the country.

SWALLOW'S TAIL, in carpentry and joinery, denotes a peculiar way of fastening together two pieces of timber so strongly as they cannot fall asunder. See **DOVE-TAILING**.

SWARDY, in agriculture, an appellation given to lands well covered with grass.

SWARM of Bees, in what manner hived, see the article **HIVING**.

The signal of the going out of a swarm from a hive is sometimes only by a humming noise made by one single bee, but that a very particularly acute and clear sound: this seems to be the voice of the new queen or female bee, calling together the swarm that is to follow her out, and animating them with a sort of martial music for the great adventure they are going to engage in.

Some who have pretended to be extremely well versed in the language of the bees, as Butler, and others, say, that this is a voice of intreaty, by which the young queen begs permission of the old queen, or parent of the hive, to take out a swarm with her to some other place: they say this noise of intreaty usually lasts about two days,

and that, at the end of that time, if the parent grants the request, she is heard to answer with a louder and clearer voice of the same kind. These noises are not to be heard, unless the ear be applied close to the place; and they say, that when this last sound is made, the new swarm may be expected certainly to go out the next day, if the weather be proper.

But he seems to have taken great pains to distinguish these sounds; he gives all the modulations of the voice of the young female, and every note that she runs into; and observes, that all these are notes of supplication, and that the sounds issued by the parent, or reigning queen of the hive, have an air of majesty, and are greatly different; and adds, that, if the young female attempts to make the sounds of the reigning bee, it is looked upon as a rebellion in the hive; and he pretends to be acquainted with the proceedings against her in these cases; he says she loses her head; and that several of the bees that followed her are treated in the same manner for having been seduced to a rebellion. *Reaumur's Hist. Insect.*

If a hive has been very well peopled during the winter, the young progeny go out early in the spring; and, if it have been very thinly peopled, it is sometimes as late as the middle of June before they go out, even without any accidental delay from the want of a queen.

The people who manage bees, are informed of the time when they are going to send out new swarms by several signs. One is, when the hive is so peopled, that many of the bees cannot find room within, but stand in clusters on the outside of the hive; another, is the appearance of a large number of drones, or male bees; these, however, are not certain signs, nor do they point out the very day of the swarming; but there is one which declares it very punctually, which is the observing, that though the hive be very full, and the day very fine, yet very few bees go out in search of honey; in this case it is a certainty that they are assembling themselves in the hive, and preparing to be gone in a very little time. If a person go near the hives that are ready to send out swarms, in the evening, or even in the night, he will hear a sort of a humming noise in them, which is not to be heard at such times on any other occasion: in short, the whole is in agitation on the occasion, and the tumult never ceases till the new colony goes out.

SWATH, *Fascia*, in surgery, a long and broad bandage, for binding up any disordered limb. See **BANDAGE**.

SWEAT, *Sudor*, a sensible moisture issuing out of the pores of the skins of animals, through too much heat, exercise, or weakness; or through the action of certain medicines called sudorifics. Under the skin above the fat are disposed all over the body what we call the military glands, which are closely united, each gland furnished with an artery, vein, and nerve, and produce an excretory duct or vessel, which passes through a perforation in the reticular body, and discharges, through a wide orifice, the sweat under the epidermis. These ducts are covered with a hollow and raised valve of a round figure, and seated under the skin; its use is to transmit or restrain the humour. This excretory duct is the principal organ of sweat, in conjunction with the vascula Ruycheiana.

The sweat thus secreted varies according to the differences of air, soil, sex, age, temperament, emunctories, diet, way of living, and time of concoction, almost in the same manner as does the urine.

Sweat is seldom or never observed in a sound body, unless from an error of the non-naturals; in its primary effects it is always hurtful, by accident it sometimes proves beneficial. See **PERSPIRATION**.

SWEATING-SICKNESS. See the article **SUDOR ANGLICANUS**.

SWEATING-HOUSE. The natives of North-America, when we first settled among them, had a great many houses to sweat in, it being their general remedy for diseases of whatever kind; but at present they are less used among them.

The cave, or sweating-house, was usually eight feet in diameter, and four feet high, the roof being supported by sticks or boards. They usually dug these caves in

the side of a hill, and as near as could be to some river, or pond. The entrance into the cave was small, and, when any person was sweating in it, the door was covered with a blanket, or skin. Near the cave they used to make a large fire, and heat in this a quantity of stones, perhaps five hundred weight; these they rolled into the cave, and piled up in a heap in the middle. When this is done, the Indians go in naked, as many as please, and sit round the heap of stones; and as soon as they begin to grow faint, which is usually in a quarter of an hour, they come out, and plunge themselves all over in the water, remaining in it a minute or two; and, repeating this a second time, they dress themselves, and go about their business.

This has been used for many ages among them with success, in case of colds, surfeits, sciaticas, and pains fixed in their limbs; and the English have often used the same means, and found relief by it. It is practised equally at all times of the year, and the Indians do it not only in sicknesses, but by way of refreshment after long journies, and other fatigues, and so strengthen themselves for any expeditions. *Philos. Transf. N^o. 384.*

SWEET, in the wine trade, denotes any vegetable juice, whether obtained by means of sugar, raisins, or other foreign or domestic fruit, which is added to wines, with a design to improve them. It is plain, says Dr. Shaw, from the making of artificial must, or stum, by means of fine sugar, with a small addition of tartar, that the art of sweet-making might receive a high degree of improvement, by the using pure sugar, as one general wholesome sweet, instead of those infinite mixtures of honey, raisins, syrups, treacle, stum, cyder, &c. where-with the sweet-makers supply the wine-coopers, to lengthen out or amend their wines: for pure sugar being added to any poor wine, will ferment therewith, and improve it, and bring it to a proper degree of strength and vinosity. If the wine that is to be amended is tart of itself, no tartar should be added to the sugar; but if it be too sweet and luscious, then the addition of tartar is necessary.

SWEET-SUBLIMATE of mercury, the same with mercurius dulcis. See **MERCURY** and **CALOMEL**.

SWELLING, in surgery. See the articles **INFLAMMATION** and **TUMOUR**.

SWIMMING, the art or act of sustaining the body in water, and of moving therein; in which action the air-bladder and fins of fishes bear a considerable part.

Some have supposed, that the motion of fish in the water, depends principally upon the pectoral fins, but the contrary is easily proved by experiment; for if the pectoral fins of a fish are cut off, it will be found to move forward or side-ways, upward or downward, as well as it did when it had them on. If a fish be carefully observed, while swimming in a basin of clear water, it will be found not to keep these pectoral fins constantly expanded, but only to open them at such times as it would stop or change its course; this seeming to be their principal, if not their only use. The pectoral and ventral fins, in the common fishes of a compressed form, serve in the same manner in keeping the fish still, and serve in scarce any other motion than that towards the bottom: so that this motion of the fish, which has been generally attributed to their fins, is almost wholly owing to their muscles, and the equipoise of their air-bladder. That the use of the pectoral and ventral fins is to keep the fish steady and upright in the water, is evident from the consequences of their loss: if they are cut off, and the fish put again into the water, it cannot continue in its natural erect posture, but staggers about and rolls from side to side. The fins of the back and anus are also of great use to the keeping the creature in its natural position, as is easily seen by cutting them off, and observing the motions of the fish afterwards.

Though a great deal depends on the motion of the muscles of the several parts of the body, in the swimming of the fish, yet the tail, and those muscles which move the lower part of the body, to which it is affixed, are the great instruments by which their swift motions in the water are performed. The moving the tail, and that part of the body to which it adheres, backward and forward, or sideways any one way, throws the whole

Fig. 6. Swimming.

Fig. 7.

whole body of the fish strongly the contrary way ; and even in swimming straight forward, the motion and direction are both greatly assisted by the vibrations of this part, as may be experienced in the motion of a boat, which, when impelled forward, may be firmly guided by means of an oar held out at its stern, and moved in the water as occasion directs. The dorsal muscles, and those of the lower part of the body between the anus and tail, are the principal that are used in the motion of this part, and these are therefore the most useful to the fish in swimming. The muscles of the belly seem to have their principal use in the contracting the belly and the air-bladder. They have been supposed of use to move the belly-fins ; but there are too many of them for such a purpose, and these fins have each its peculiar muscle fully sufficient to the business. The use of the tail in swimming is easily seen, by cutting it off, and committing the fish to the water without it, in which case it is a most helpless creature.

Let A B (plate CXXIII. fig. 6.) be a fish swimming : by expanding or contracting its air-bladder L, it can rise or sink in the water at pleasure ; and its direct motion is performed by means of its tail B C D, vibrating from one side to another, which is performed thus ; suppose the tail in the position F G, (fig. 7.) being about to be moved successively to H, I, and K ; the fish first turns the end G, oblique to the water, and moves it quickly towards K ; the resistance of the water, acting in the mean time obliquely, moves him partly forward and partly sideways ; but this lateral motion is corrected by the next stroke, from K towards I, K, and G ; which is performed by turning the tail obliquely the contrary way to what it was in the first stroke. By the help of the tail they also turn about, by striking strongly with it on one side, and keeping it bent, so as to act like the rudder of a ship. The fins, especially the pectoral ones E, E, serve to keep the fish upright, as also to ascend and descend.

Brutes swim naturally, but men attain this art by practice and industry : it consists principally in striking alternately with the hands and feet ; which, like oars, row a person forward : he must keep his body a little oblique, that he may the more easily erect his head, and keep his mouth above water.

SWINE, in zoology, a general name for the *fus* or hog-kind. See HOG.

Swine are very profitable creatures to the owner, being kept at small expence, feeding on things that would be otherwise thrown away, and producing a very large increase. They are apt to dig up the ground, and to break fences ; but this may be prevented, by putting rings in their noses, and yokes about their necks. Leicester-shire, Northamptonshire, and Hampshire, are famous for these animals, which seems owing to their being clayey countries, and that more beans and pease are sown there, than in other places. The wild kind never grow so large as the tame, but they are much better tasted. The keepers of hogs should always chuse such boars to breed out of as are long-bodied, and have deep bellies and sides, short noses, thick thighs, short legs, high claws, a thick neck, and a thick chine, well set with large bristles.

It is not proper to keep too many breeding sows ; for they will produce so many young at a time, and this three times a year, that they will not find food enough. They usually bring thirteen or fourteen young ones in a litter, sometimes more ; but they can bring up no more than they have teats to suckle.

Young shoots, as they are called, that is, swine of three quarters of a year old, are best for pork, and those of a year and half, for bacon. Moist and sedgy grounds are good for swine, for they eat the roots of many of the plants that grow there ; and the fruit of the beech, chesnut, and hedgebushes, fatten them well, and make their flesh much better tasted, than when bred intirely in the sty. *Mortimer's Husbandry.*

SWINGLING, the beating of flax, or hemp, after it has been well broken with the brake : this is done by taking up the flax in handfuls, and then beating it with

a rod, or a flatted and smooth stick, in order to free it from the bun, and prepare it for being heckled.

SWITZERLAND, or SWISSERLAND, called Helvetia by the Romans, is bounded by the Suntgow, the Hircinian forest, and other parts of Swabia, on the north ; by the lake of Constance, also Tyrol and Trent, on the east ; by Savoy, Milan, and other provinces of Italy, on the south ; and by Burgundy and Franche-Comté on the west. It is about two hundred and sixty miles long, and upwards of a hundred broad ; some parts of Italy and France being now included in it, which did not belong to the ancient Helvetii.

There are thirteen provinces or cantons in this country.

SWOONING, in medicine, a species of lipothymy, wherein the patient is deprived of all sense and motion. See LYPOTHYMIA.

SWORD, *Gladius*, an offensive weapon worn at the side, and serving either to cut or stab ; its parts are the handle, guard, and blade ; to which may be added the bow, scabbard, pommel, &c. Fencing-masters, however, divide the sword into the upper, middle, and lower part ; or the sort, middle, and foible. See the article FENCING.

SYCAMORE-TREE, in botany, the English name of the *acer major*, or greater maple. See the article MAPLE.

SYCOPHANT, *συκοφαντης*, a Greek term originally used at Athens for persons who made it their business to inform against those who stole figs, or against those, who, contrary to the law, which prohibited the exportation of them, practised the thing, and deceived the officers, the inspectors of the ports, &c.

The word is formed from *συκ*, a fig, and *φαίνω*, *indicō*, to shew, or discover. At length the term became used in the general for all informers, tale-bearers, parasites, flatterers, &c. especially those in the courts of princes : and at last for lyars, impostors, &c.

SYLLABLE, in grammar, a part of a word consisting of one or more letters which are pronounced together.

The word is derived from the Greek, *συλλαβη*, which literally denotes comprehension, or assemblage.

Or syllable is a complete word, uttered in one breath, consisting either of a vowel alone, or of a vowel and one or more consonants, not exceeding seven.

SYLLABUB, a compound liquor made of white wine and sugar, into which is put new milk. If cream be used instead of milk, it is called whipt syllabub.

SYLLABUS, in matters of literature, denotes a table of contents, or an index of the chief heads of a book or discourse.

SYLLEPSIS, in Latin and Greek grammar, a figure whereby we conceive the sense of words otherwise than the words import ; and thus make our construction, not according to the words, but the intention of the author.

It is also used for the agreement of a verb or adjective, not with that word next it, but with the most worthy in the sentence, as *rex et regina beati*.

SYLLOGISM, in logic, an argument, or form of reasoning, consisting of three propositions ; having this property, that the conclusion necessarily follows from the two premises : so that if the first and second proposition be granted, the conclusion must be granted in like manner, and the whole allowed for a demonstration.

As the first work of the mind is perception, whereby our ideas are framed, and the second is judgment, which joins or disjoins our ideas, and forms a proposition, so the third operation of the mind is reasoning, which joins several propositions together, and makes a syllogism, that is an argument whereby we are wont to infer something that is less known, from truths which are more evident.

In treating of this subject, let us consider more particularly, 1. The nature of a syllogism, and the parts of which it is composed. 2. The several kinds of syllogisms, with particular rules relating to them. 3. The doctrine of sophisms, or false reasoning, together with the means of avoiding them, and the manner of solving or answering them. 4. Some general rules to direct our reasoning.

If the mere perception and comparison of two ideas would always shew us whether they agree or disagree; then all rational propositions would be matters of intelligence, or first principles, and there would be no use of reasoning or drawing any consequences. It is the narrowness of the human mind which introduces the necessity of reasoning. When we are unable to judge of the truth or falshood of a proposition in an immediate manner, by the mere contemplation of its subject and predicate, we are then constrained to use a medium, and to compare each of them with some third idea, that by seeing how far they agree or disagree with it, we may be able to judge how far they agree or disagree among themselves: as, if there are two lines, A and B, and we know not whether they are equal or no, we take a third line C, or an inch, and apply it to each of them; if it agree with them both, then we infer that A and B are equal; but if it agree with one and not with the other, then we conclude A and B are not equal: if it agree with neither of them, there can be no comparison.

So if the question be, whether God must be worshipped, we seek a third idea, suppose the idea of a Creator, and say, "Our Creator must be worshipped; God is our creator; therefore God must be worshipped." The comparison of this third idea with the two distinct parts of the question, usually requires two propositions, which are called the premises: the third proposition which is drawn from them is the conclusion, wherein the question itself is answered, and the subject and predicate joined either in the negative or the affirmative.

The foundation of all affirmative conclusions is laid in this general truth, that so far as two proposed ideas agree to any third idea, they agree also among themselves. The character of creator agrees to God, and worship agrees to a creator, therefore worship agrees to God.

The foundation of all negative conclusions is this, that where one of the two proposed ideas agrees with the third idea, and the other disagrees with it, they must needs disagree so far also with one another; as, if *no sinners are happy*, and if *angels are happy*, then *angels are not sinners*.

Thus it appears what is the strict and just notion of a syllogism: it is a sentence or argument made up of three propositions so disposed, as that the last is necessarily inferred from those which go before, as in the instances which have been just mentioned.

In the constitution of a syllogism two things may be considered, viz. the matter and the form of it. The matter of which a syllogism is made up, is three propositions; and these three propositions are made up of three ideas or terms variously joined. The three terms are called the remote matter of a syllogism; and the three propositions the proximate or immediate matter of it.

The three terms are named the major, the minor, and the middle. The predicate of the conclusion is called the major term, because it is generally of a larger extension than the minor term, or the subject. The major and minor terms are called the extremes. The middle term is the third idea invented and disposed in two propositions in such a manner as to shew the connexion between the major and minor term in the conclusion; for which reason the middle term itself is sometimes called the argument. That proposition which contains the predicate of the conclusion connected with the middle term, is usually called the major proposition, whereas the minor proposition connects the middle term with the subject of the conclusion, and is sometimes called the assumption.

Note, This exact distinction of the several parts of a syllogism, and of the major and minor terms connected with the middle term, in the major and minor propositions, does chiefly belong to simple or categorical syllogisms, though all syllogisms whatever have something analogical to it.

Note farther, that the major proposition is generally placed first, and the minor second, and the conclusion in the last place, where the syllogism is regularly composed and represented.

The form of a syllogism is the framing and disposing of the premises according to art, or just principles of reasoning, and the regular inference of the conclusion from them.

The *act of reasoning*, or inferring one thing from another, is generally expressed and known by the particle *therefore*, when the argument is formed according to the rules of art; though in common discourse or writing, such *causal* particles as *for*, *because*, manifest the act of reasoning as well as the *illative* particles *then* and *therefore*: and wheresoever any of these words are used, there is a perfect syllogism expressed or implied, though perhaps the three propositions do not appear, or are not placed in regular form.

Syllogisms are divided into various kinds, either according to the question which is proved by them, according to the nature and composition of them, or according to the middle term, which is used to prove the question. According to the question which is to be proved, so syllogisms are divided into universal affirmative, universal negative, particular affirmative, and particular negative. This is often called a division of syllogisms drawn from the conclusion; for so many sorts of conclusions there may be which are marked with the letter A, E, I, O.

In an universal affirmative syllogism, one idea is proved universally to agree with another, and may be universally affirmed of it, as "Every sin deserves death; every unlawful wish is a sin; therefore every unlawful wish deserves death."

In an universal negative syllogism, one idea is proved to disagree with another idea universally, and may be thus denied of it: "As no injustice can be pleasing to God, all persecution for the sake of conscience is injustice; therefore no persecution for conscience sake can be pleasing to God."

Particular affirmative, and particular negative syllogisms may be easily understood by what is said of universals, and there will be sufficient examples given of all these hereafter.

The general principle upon which these universal and particular syllogisms are founded is this, whatsoever is affirmed or denied universally of any idea, may be affirmed or denied of all the particular kinds or beings, which are contained in the extension of that universal idea. So the desert of death is affirmed universally of sin, and an unlawful wish is one particular kind of sin, which is contained in the universal idea of sin, therefore the desert of death may be affirmed concerning an unlawful wish. And so of the rest.

The next division of syllogisms is into single and compound. This is drawn from the nature and composition of them. Single syllogisms are made up of three propositions; compound syllogisms contain more than three propositions, and may be formed into two or more syllogisms.

Single syllogisms, for distinction's sake, may be divided into simple, complex, and conjunctive. These are properly called simple or categorical syllogisms, which are made up of three plain, single, or categorical propositions, wherein the middle term is evidently and regularly joined with one part of the question in the major proposition, and with the other in the minor, whence there follows a plain single conclusion; as, "Every human virtue is to be sought with diligence; prudence is a human virtue; therefore prudence is to be sought diligently."

Though the terms of propositions may be complex; yet where the composition of the whole argument is thus plain, simple, and regular, it is properly called a simple syllogism, since the complexion does not belong to the syllogistic form of it.

Simple syllogisms have several rules belonging to them, which being observed, will generally secure us from false inferences: but these rules being founded on four general axioms, it is necessary to mention these axioms before-hand, for the use of those who will enter into the speculative reason of all these rules. 1. Particular propositions are contained in universals, and may be inferred from them; but universals are not contained in particulars, nor can be inferred from them. 2. In all universal propositions, the subject is universal: in all particular propositions the subject is particular. 3. In all affirmative propositions, the predicate has no greater extension than the subject; for its extension is restrained by the subject, and therefore it is always to be esteemed

as a particular idea. It is by mere accident, if it ever be taken universally, and cannot happen but in such universal or singular propositions as are reciprocal. 4. The predicate of a negative proposition is always taken universally, for in its whole extension it is denied of the subject. If we say *no stone is vegetable*, we deny all sorts of vegetation concerning stones.

The rules of simple, regular syllogisms are these: 1. The middle term must not be taken twice particularly, but once at least universally. For if the middle term be taken for two different parts or kinds of the same universal idea, then the subject of the conclusion is compared with one of these parts, and the predicate with another part, and this will never shew whether that subject and predicate agree or disagree; there will then be four distinct terms in the syllogism, and the two parts of the question will not be compared with the same third idea; as if we say, *some men are pious*, and *some men are robbers*, we can never infer that *some robbers are pious*, for the middle term men being taken twice particularly, it is not the same men who are spoken of in the major and minor propositions. 2. The terms in the conclusion must never be taken more universally than they are in the premises. The reason is derived from the first axiom, that generals can never be inferred from particulars. 3. A negative conclusion cannot be proved by two affirmative premises. For when the two terms of the conclusion are united or agree to the middle term, it does not follow by any means that they disagree with one another. 4. If one of the premises be negative, the conclusion must be negative. For if the middle term be denied of either part of the conclusion, it may shew that the terms of the conclusion disagree, but it can never shew that they agree. 5. If either of the premises be particular, the conclusion must be particular. This may be proved for the most part from the first axiom.

These two last rules are sometimes united in this single sentence. The conclusion always follows the weaker part of the premises. Now negatives and particulars are counted inferior to affirmatives and universals. 6. From two negative premises nothing can be concluded. For they separate the middle term both from the subject and predicate of the conclusion, and when two ideas disagree to a third, we cannot infer that they either agree or disagree with each other.

Yet where the negation is a part of the middle term, the two premises may look like negatives according to the words, but one of them is affirmative in sense: as, What has no thought cannot reason; but a worm has no thought; therefore a worm cannot reason. The minor proposition does really affirm the middle term concerning the subject, viz. a worm is what has no thought, and thus it is properly in this syllogism an affirmative proposition. 7. From two particular premises nothing can be concluded. This rule depends chiefly on the first axiom.

Simple syllogisms are adorned and surrounded in the common books of logic with a variety of inventions about moods and figures, wherein by the artificial contexture of the letters A, E, I, and O, men have endeavoured to transform logic, or the art of reasoning, into a sort of mechanism, and to teach boys to syllogise, or frame arguments and refute them, without any real inward knowledge of the question.

All the possible compositions of three of the letters, A, E, I, O, to make three propositions amount to sixty-four; but fifty-four of them are excluded from forming true syllogisms by the seven rules already mentioned: the remaining ten are variously diversified by figures and moods into fourteen syllogisms.

The figure of a syllogism is the proper disposition of the middle term with the parts of the question. A mood is the regular determination of propositions according to their quantity and quality, that is, their universal or particular affirmation or negation; which are signified by certain artificial words wherein the consonants are neglected, and these four vowels A, E, I, O, are only regarded. There are generally reckoned three figures.

In the first of them the middle term is the subject of the major proposition, and the predicate of the minor. This contains four moods, viz. Barbara, Celarent, Darii, Ferio. And it is the excellency of this figure that

all sorts of questions or conclusions may be proved by it, whether A, E, I, or O, that is, universal or particular, affirmative or negative, as,

- Bar- Every wicked man is truly miserable;
- ba- All tyrants are wicked men;
- ra- Therefore all tyrants are truly miserable.
- Ce- He that is always in fear is not happy;
- la- Covetous men are always in fear;
- rent- Therefore covetous men are not happy.
- Da- Whatsoever furthers our salvation is good for us;
- ri- Some afflictions further our salvation;
- i- Therefore some afflictions are good for us;
- Fe- Nothing that must be repented of is truly desirable;
- ri- Some pleasures must be repented of;
- o- Therefore there are some pleasures which are not truly desirable.

In the second figure the middle term is the predicate of both the premises; this contains four moods, viz. Cesare, Camestres, Festino, Baroco, and it admits only of negative conclusions; as,

- Ce- No liar is fit to be believed;
- fa- Every good Christian is fit to be believed;
- re- Therefore no good Christian is a liar.

The reader may easily form examples of the rest.

The third figure requires that the middle term be the subject of both the premises. It has six moods, viz. Darapti, Felapton, Disamis, Datisi, Bocardo, Ferison; and it admits only of particular conclusions; as,

- Da- Whosoever loves God shall be saved;
- rap- All the lovers of God have their imperfections;
- ti- Therefore some who have imperfections shall be saved.

From what has been already said, we shall leave the reader to form examples of the rest.

Complex SYLLOGISMS. — It is not the mere use of complex terms in a syllogism that gives it this name, though one of the terms is usually complex; but those are properly called complex syllogisms, in which the middle term is not connected with the whole subject, or the whole predicate in two distinct propositions, but is intermingled and compared with them by parts, or in a more confused manner, in different forms of speech; as,

- The sun is a senseless being;
- The Persians worshipped the sun;
- Therefore the Persians worshipped a senseless being.

Here the predicate of the conclusion is worshipped a senseless being, part of which is joined with the middle term sun in the major proposition, and the other part in the minor.

Though this sort of argument is confessed to be entangled, or confused, and irregular, if examined by the rules of simple syllogisms; yet there is a great variety of arguments used in books of learning, and in common life, whose consequence is strong and evident, and which must be ranked under this head; as,

1. Exclusive propositions will form a complex argument; as, "Pious men are the only favourites of heaven; true Christians are favourites of heaven; therefore true Christians are pious men." Or thus, "Hypocrites are not pious men; therefore hypocrites are no favourites of heaven."

2. Exceptive propositions will make such complex syllogisms; as, "None but physicians came to the consultation; the nurse is no physician; therefore the nurse came not to the consultation."

3. Comparative propositions; as, "Knowledge is better than riches; virtue is better than knowledge; therefore virtue is better than riches." Or thus, "A dove will fly a mile in a minute; a swallow flies swifter than a dove: therefore a swallow will fly more than a mile in a minute."

4. Inceptive and desitive propositions; as, "The fogs vanish as the sun rises; but the fogs have not yet begun to vanish; therefore the sun is not yet risen."

5. Modal propositions; as, "It is necessary that a general understands the art of war; but Caius does not understand the art of war; therefore it is necessary Caius should not be a general: Or thus, "A total eclipse

eclipse of the sun would cause darkness at noon; it is possible that the moon at that time may totally eclipse the sun; therefore it is possible that the moon may cause darkness at noon."

Beside all these, there are a great number of complex syllogisms, which can hardly be reduced under any particular titles, because the forms of human language are so exceeding various.

Conjunctive SYLLOGISM. Those are called conjunctive syllogisms, wherein one of the premises, namely the major, has distinct parts, which are joined by conjunction, or some such particle of speech. Most times the major or minor, or both, are explicitly compound propositions; and generally the major proposition is made up of two distinct parts or propositions, in such a manner, as that by the assertion of one in the minor, the other is either asserted or denied in the conclusion: or by the denial of one in the minor, the other is either asserted or denied in the conclusion. It is hardly possible indeed to fit any short definition to include all the kinds of them; but the chief amongst them are the conditional syllogism, the disjunctive, the relative, and the connexive.

The conditional or hypothetical syllogism is whose major or minor, or both, are conditional propositions; as, "If there be a God, the world is governed by providence; but there is a God; therefore the world is governed by providence."

These syllogisms admit two sorts of true argumentation, where the major is conditional.

1. When the antecedent is asserted in the minor, that the consequent may be asserted in the conclusion; such is the preceding example. This is called arguing from the position of the antecedent to the position of the consequent.

2. When the consequent is contradicted in the minor proposition, that the antecedent may be contradicted in the conclusion; as, "If atheists are in the right, then the world exists without a cause, but the world does not exist without a cause; therefore atheists are not in the right." This is called arguing from the removing of the consequent to the removing of the antecedent.

To remove the antecedent or consequent here does not merely signify the denial of it, but the contradiction of it; for the mere denial of it by contrary proposition will not make a true syllogism as appears thus: "If every creature be reasonable, every brute is reasonable; but no brute is reasonable; therefore no creature is reasonable." Whereas if you say in the minor, but "Every brute is not reasonable," then it would follow truly in the conclusion, therefore "Every creature is not reasonable."

When the antecedent or consequent are negative propositions they are removed by an affirmative; as, "If there be no God, then the world does not discover creating wisdom; but the world does not discover creating wisdom; therefore there is a God." In this instance the consequent is removed or contradicted in the minor, that the antecedent may be contradicted in the conclusion. So in this argument of St. Paul, 1 Cor. xv. "If the dead rise not, Christ died in vain; but Christ did not die in vain; therefore the dead shall rise."

A disjunctive syllogism is when the major proposition is disjunctive; as, "The earth moves in a circle or an ellipsis; but it does not move in a circle; therefore it moves in an ellipsis."

A disjunctive syllogism may have many members or parts; thus, "It is either spring, summer, autumn, or winter; but it is not spring, autumn, or winter; therefore it is summer."

The true method of arguing here is from the assertion of one, to the denial of the rest, or from the denial of one or more, to the assertion of what remains; but the major should be so framed, that the several parts of it cannot be true together, though one of them is evidently true.

A relative syllogism requires the major proposition to be relative; as, "Where Christ is, there shall his servants be; but Christ is in heaven; therefore his servants shall be there also." Or, "As is the captain, so are his soldiers; but the captain is a coward; therefore his soldiers are so too."

Arguments that relate to the doctrine of proposition, must be referred to this head; as, "As two are to four, so are three to six; but two make the half of four; therefore three make the half of six."

Besides these, there is another sort of syllogism which is very natural and common, and yet authors take very little notice of it, call it by an improper name, and describe it very defectively, and that is,

A connexive syllogism. This some have called copulative; but it does by no means require the major to be a copulative nor a compound proposition; but it requires that two or more ideas be so connected either in the complex subject or predicate of the major, that if one of them be affirmed or denied in the minor, common sense will naturally shew us what will be the consequence. It would be very tedious and useless to frame particular rules about them: let therefore these two observations be sufficient. 1. Most of them may be transformed into categorical syllogisms by those who have a mind to prove the truth of them that way; or they may be easily converted into each other by changing the forms of speech. 2. These conjunctive syllogisms are seldom deficient or faulty in the form of them; for such a deficiency would be discovered at first glance generally by common reason, without any artificial rules of logic: the chief care therefore is to see that the major proposition be true, upon which the whole force of the argument usually depends.

Compound SYLLOGISMS. We properly call those compound syllogisms which are made of two or more single syllogisms, and may be resolved into them. The chief kinds are these, Epichireme, Dilemma, Prosyllogismus, and Sorites. See each under their proper heads. *Watts's Logic.*

SYMBOL, Symbolum, a sign or representation of any moral thing by the images or properties of natural things.

The word is formed from the Greek *συμβολον*, a mark, sign, or badge, and that from the verb *συμβαλλειν*, *conferre*, to compare.

SYMMETRY, συμμετρια, relation of parity both in respect of height, length, and breadth of parts necessary to compass a beautiful whole.

The word is formed from the Greek, *συν*, with, and *μετρον*, measure.

SYMPATHETIC, something that has a sympathy, or that acts, or is acted on, by sympathy.

Sympathetic is also particularly applied to all diseases which have two causes, the one remote, and the other near.

SYMPATHETIC INK. See the article *Sympathetic Ink*.

SYMPATHETIC POWDER. The composition of the famous sympathetic powder, used at Gosselaer by the miners in all their wounds, is this. Take of green vitriol, eight ounces: of gum tragacanth, reduced to an impalpable powder, one ounce; mix these together, and let a small quantity of the powder be sprinkled on the wound, and it immediately stops the bleeding. The vitriol is to be calcined to whiteness in the sun, before it is mixed with the gum.

SAMPATHY, συμπαθεια, an agreement of affections and inclinations, or a conformity of natural qualities, humours, temperaments, &c. which make two persons delighted and pleased with each other.

In medicine, sympathy denotes an indisposition befalling one part of the body, through the defect or disorder of another; whether it be from the affluence of some humour, or vapour sent from elsewhere; or from the want of the influence of some matter necessary to its action.

SYMPHONY, in music, properly denotes a consonance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also harmony.

The word is formed from the Greek *συν*, with, and *φωνη*, sound.

SYMPHYSIS, in anatomy, one of the kinds of junctures, or articulation, of the bones. See *ARTICULATION*.

SYMPLEXIUM, in natural history, the name of a genus of fossils, of the class of the scintillæ, but not of the

the determinate and regular figure of most of the genera of those bodies; but composed of various irregular connections of differently shaped, and usually imperfect, bodies.

The word is derived from the Greek *συμπλεω*, to connect or compound a mixed mass of different things.

SYMPOSIARCH, in antiquity, the director or manager of an entertainment.

SYMPTOM, *συμπτωμα*, in medicine, any appearance in a disease, which serves to indicate or point out its cause, approach, duration, event, &c.

SYMPTOM, in a large acceptation, signifies whatever preternaturally befalls a person, whether it be a disease, a morbid cause, or supervening preternatural accident. In a strict sense it means no more than the third or last species; that is, the consequences of diseases, and of their causes, exclusive of the diseases and causes themselves, and so is no other than a preternatural affection, which follows the disease, as the shadow follows the body.
